The temporary statistics are in a measure approximate, and consist of details obtained from day to day or from week to week, to guide the officer while operations are in actual progress — as examples the following are given :

Statements of approximate weekly earnings;
— of (received) traffic on hand at stations (daily);
— of traffic requiring transport in through and in local service (daily);
— of train loads (tonnage) in comparison with haulage capacity of engines (daily);
— of weight of traffic in vehicles in comparison with capacity of such vehicles (weekly or monthly);
— of train and vehicle mileage (weekly);
— of train and wagon miles per engine hour (weekly or monthly);
— of trucks under load at stations (daily);
— of rolling stock on hand (daily).

Note. — In connection with such statistics, it is of interest to note that the controversy some few years ago as to the relative merits of ton mileage statistics (as compared with the particulars on which English railway managers relied) was probably due to the failure to recognise the necessity for temporary statistics. The value of properly prepared ton mileage records is, in the writer's experience, undoubted. But at best the records can only be available some time after the traffic has been carried, and in the meantime, the needs of the operating officials require to be met by means of temporary statistics.

Permanent statistics.

The permanent statistics, on the other hand, comprise actual ascertained results collected and presented as early as may be possible for scrutiny, enquiry, and consideration after the operations are over. These statistics are especially valuable if they enable comparisons to be usefully made with earlier periods or with results attained on other lines. If the interval between the operations they record and the time of their presentation is not long, they are extremely valuable to the Administration as a record of what has been accomplished. They often also indicate directions in which it is possible to attract profitable trade and to curtail avoidable expenditure, without sacrifice of efficiency. If judiciously prepared and well balanced, they are especially valuable in enabling the Administration to form a judgment in regard to such matters as proposals for additional facilities to the public using the railway, inasmuch as they serve to indicate whether such additional services will be remunerative or not.

They should also be concise and to the point, for as a rule, the administrator of a railway has the current operations of his lines to attend to, and gets but little leisure time in which to digest voluminous statements. What is placed before him should render it possible for him to take a survey of the month's operations and take cognisance of any salient features without the expenditure of much time.

To secure this, it is essential that the preparation of such statistics should be entrusted to trained officers who fully recognise that their purpose is not so much to serve criticism as to guide and help the administrators in their work of supervising operation — work which is at best both arduous and harassing.

It is scarcely necessary to add that those on whom the duty of preparing or scrutinising the figures rests should be keenly alive to the importance of bringing to notice facts which indicate possibilities of increasing the traffic of the lines or securing better results of operation or increased comfort and contentment of the travelling public and the railway staff.

Similarly it goes almost without saying that one set of statistics, however valuable, without the corrective supplied by others, cannot fail to lead astray. For instance, statistics based on train mileage alone may often give an impression which is at variance with actual facts, and ton mileage statistics are themselves of limited value without figures of train mileage, earnings, tonnage of traffic (and its direction) at certain principal stations or districts. Such figures must be supplemented also by knowledge of traffic and working considerations, which can only be partly expressed in statistics.

Subject to the foregoing general observations, a somewhat detailed analysis of the principles on which the statistics prepared on British Colonial railways are based, together with information as to the statistics which the experience of the working of the railways under the charge of the Reporter, has indicated as the most suitable, is submitted for the consideration of the Congress.

b) Accounts.

The construction and equipment of a railway involves considerable expenditure. It is essential that proper records should ke kept of the money raised for, and the expenditure involved in, bringing the line up to the stage when it begins to earn revenue and in carrying out any subsequent extensions or substantial improvements. It is equally important when the line is opened that proper accounts should be kept of the earnings from operation and of the working expenditure, interest, and all other charges, as well as of the resulting profit or loss, as the case may be.

As has already been pointed out, the accounts of a railway form the foundation of much statistical data, and the importance of securing, at the outset, such a uniform system of accounts as will readily admit of the preparation of such statistical data is worthy of careful consideration.

Nature of railway capital expenditure.

If the items of capital expenditure in connection with railways are analysed, it will be seen that they fall under fairly well defined heads, namely :

1° Permanent way, works, and accessories (including station buildings);
2° Equipment : engines and rolling stock;
3° General buildings, workshops, offices, stores, etc.;
4° General expenses and cost of raising capital.

In addition to the above there is, in the case of many railways, capital expenditure in connection with such outside operations as docks and wharves, hotels, grain elevators, etc., which should be kept distinct from railway capital expenditure proper.

Form of capital account.

The Capital Accounts of very few colonial railways give particulars of capital expenditure. Sometimes, however, the capital cost of each of the different sections of the line is shown, such items of capital expenditure as are common to one or more sections being pro-rated on some arbitrary basis.

While the desirability of keeping records of capital expenditure under sections cannot be questioned, it appears to the writer that such sectional records should be subordinate to the main statement of capital expenditure, which would show the totals of the different items making up the cost of the railway system (such as permanent way, works, equipment, etc.) in such order as will facilitate analysis under sections.

In considering to what extent records in detail should also be kept of the cost of particular works, equipment, and appliances, regard should be had to the fact that, notwithstanding the most liberal provision for maintenance and repair, capital assets of almost every nature, except land, are subject to deterioration, and if the capital account of an administration is to remain accurate, it is absolutely necessary to keep proper records of the cost of each class of such assets. By this means only can the necessary adjustment be made when the asset goes out of service or is condemned.

Balance-sheet.

That comparatively few British Colonial railways prepare a regular " Capital Account " and " Balance-Sheet " showing their financial position, is probably due to the finances of the railways being more or less intimately bound up with those of the colony itself. The value of such statements in connection with the study of railway working is so considerable, that the writer is induced to subjoin draft specimens (1) of forms based on accounts actually prepared in British Colonies, so as to bring under discussion the question of the standardisation of railway accounts and returns of this nature.

In the case of many British Colonial railways, the complete adoption of standard forms would not be possible without more or less divorcing railway accounts from the ordinary Goverment accounts, but on the Central South African Railways, this step has been taken with results which leave nothing to be desired, either from the standpoint of the Government or the Railway Administration.

Revenue account and net revenue account.

The importance of setting out clearly the earnings and expenditure of lines open for traffic is generally recognised throughout the British Colonies, but unfortunately there is a want of uniformity in the manner of doing this. To begin with, there is no common understanding as to the heads under which either earnings or expenditure shall be kept. In some cases, earnings are made to include the receipts from departments worked by the railway which are not strictly a part of the ordinary services of transportation. Again, some Administrations show under " Earnings " only *cash actually received* (a practice adopted from English Government accounts), while others, correctly, record their whole earnings, whether such earnings have been actually received or not.

In regard to the recording of expenditure, similar diversity of practice exists, and will be dealt with in detail later on in the course of this paper.

No uniformity can be attained and no useful comparisons can be instituted between one railway and another, unless some general principles are adopted which will eliminate at any rate the most serious differences in present practice. The following proposals are submitted for consideration :

1° That each Administration should keep a " Revenue Account ", which would be *credited* under suitable heads with amounts earned (whether collected or not) for services directly and necessarily connected with transportation by rail; *debited* under suitable heads with the cost (whether actually paid or not) of maintaining the railway and the equipment, of working the traffic, of management, and of other services directly and necessarily connected therewith.

2° That each Administration should keep a " Net Revenue Account " and an

(1) See part 5.

" Appropriation Account ". These accounts would be dealt with as follows :

NET REVENUE ACCOUNT would be credited with the gross profit over working expenses (brought from the " Revenue Account " referred to in 1° above) and would also be credited or debited with the following items according as same represent profit or loss :

a) Net profit or loss on lines leased.

b) Net profit or loss on working of Cartage Department, Catering Department and Hotels, Steamer Services, Tramway Services, Bookstalls, House Property, Other separate Departments which are in the nature of outside investments.

c) { Interest earned on investments (Credit).
{ Interest paid on fixed Railway Loans (Debit).

d) Bad debts and losses written off (Debit).

APPROPRIATION ACCOUNT would be *credited* with :

1° The balance of net Profits shown in the Appropriation Account for the previous year.

2° The profit for the current period as shown in the Net Revenue Account above referred to.

It would be *debited* with any amounts appropriated from profits for such purposes as.

a) Improvements of railway property;

b) Redemption of Capital or Loans;

c) Acquisition of new Capital Assets (capital expenditure from profits);

d) Dividends to Shareholders.

3° That any refunds of revenue should be deducted from the revenue affected and not be shown as expenditure.

4° That any expenditure of a recoverable nature should not be included as part of the expenditure shown in the Revenue Account or the Net Revenue Account but debited to a Suspense Account pending recovery.

5° That where rolling stock is hired from or loaned to another administration, on payment, the net earnings or expenditure only should be shown in Revenue Account.

6° That expenditure on such services as relaying large sections of a line, replacing buildings, renewals of locomotives and rolling stock, should either be provided for out of Renewals Funds created and maintained by the inclusion in the working expenditure accounts of regular charges for depreciation (preferably under a separate head or separate sub-heads) or should be recorded separately under each head of working expenditure shown in Revenue Account.

7° That any revenue represented by charges raised for haulage of the administration's stores and material over home lines should be shown separately in Revenue Account and not included under the ordinary heads of traffic earnings. The advantage of creating debits for all such services as a check upon unnecessary haulage is undoubted.

Specimen forms of Revenue, Net Revenue and Appropriation Accounts which will serve to explain more clearly what is suggested are attached (1).

EARNINGS.

The main sources of railway revenue are

a) the transport of passengers (with their luggage) and goods (including live stock and minerals).

b) Other services not so directly connected with transportation—such as storage, cloakroom receipts, etc.

Such a division of earnings would be inadequate for any except the very smallest administration. It is somewhat important, however, that it should form the basis of any more extended classification, since it distinguishes clearly between those earnings arising directly from the conveyance of traffic and those which are more or less incidental thereto.

Classification of traffic earnings.

A logical method for the further subdivision of transportation earnings is indicated by the different quality of the services rendered in connection with the conveyance of the traffic. Passengers, their luggage, mail matter, and parcels are usually carried in trains running at higher rates of speed; the stations and vehicles provided are usually of more costly construction and both earnings and expenditure in connection with the traffic are high in comparison with those for the conveyance of other traffic.

If any idea at all of the relative profitableness of the different classes of work done by an administration is to be obtained the accounts should record separately the receipts for services performed by passenger trains as distinct from goods trains.

Then again, the earnings of goods trains must be subdivided where the traffic is at all large, the extent of the subdivision varying according to the nature and volume of the traffic carried. Differences in the vehicular accommodation provided and the existence in one case, and absence in another, of special expenses in connection with conveyance would suggest as natural the following subdivision of the goods earnings :

a) Live stock;

(1) See part 5.

b) Goods;
c) Minerals.

Classification of earnings incidental to traffic.

The subdivision of earnings from operations not so closely connected with the conveyance of traffic might quite well be effected so as to conform to the same general order as the subdivision of the previous main head, *i. e.* the first class would be earnings, which are more particularly connected with the coaching service and the second those earnings which relate rather to the goods service. A third subdivision would consist of those earnings which are quite general in character, and do not specially pertain to either the passenger or goods services.

EXPENDITURE.

Expenditure.

The second part of this paper deals with the classification of railway working expenditure, and it is only necessary to mention here such general principles as appear to be essential to the preparation of " unit " statistics (that is, statistics such as the cost of any particular service per ton, per open mile, per train mile, etc.).

A perusal of the replies received from the various Colonies makes it apparent that the uniform observance of a few cardinal principles in the classification of expenditure would not only be of general advantage as admitting of ready comparisons between one railway and another, but would give each Administration, at trifling cost, information as to the working of the lines controlled, which could otherwise only be obtained by the preparation of special returns or statements at considerable cost. Moreover, the adoption of such principles would render easier the preparation of other statistics of railway working.

The position of a railway is that it has transport to sell, and its interest lies in disposing of it in the manner best calculated to yield the largest net revenue, due regard being had to other considerations always present with a good seller.

To arrive at this result, it is obviously necessary to know, as accurately as may be possible, the cost of each service that goes to make up in the aggregate the performance of transport, and the preparation of such information can be much more accurately and readily obtained if expenditure is classified *according to the nature of the services rendered* and not according to departments. If this principle were adopted a clear distinction would be drawn between :

a) Services directly connected with railway working, *i. e.*, the service of transportation;
b) Services not directly connected with the actual service of transportation (such as cartage, catering, hotels, etc.)

On most railways from which replies have been received, subdivision of expenditure is effected according to departments (following the usual English practice). As radical changes have already been made in the organisation of certain British

Colonial railways. The position at the present time is that some services which are in one administration performed by one department are in another entrusted to quite a different department, and any comparisons between railways with different types of organisation are consequently rendered either impossible or misleading. As the classes of work to be done on railways are more or less the same all over the world, these seem to afford by far the best divisions of the expenditure. If adopted, they would give the following as the main heads of railway working expenditure :

1° Maintenance of the permanent way and works, bridges, station and other buildings used in connection with the operation of the line, fencing, telegraph lines, signals, etc.;
2° Maintenance of equipment, *viz.*, locomotives and rolling stock;
3° Transportation and Traffic : expenditure for working and supervising the traffic;
4° General Administration : charges common to all services connected with the working of the railway.

The subdivision of such heads of expenditure would be effected so as to reflect as far as possible the cost of the different services rendered, special importance being attached to grouping items and sub-heads according to the proximity of the service to the actual conveyance of traffic.

The same observations apply in respect to subsidiary services undertaken either to make transport more attractive to the buyer, or else to procure revenue in diminution of the cost of carrying out the work, (including such services as catering and refreshments and advertising at stations).

c) Statistics of Physical Condition of Property and Equipment.

Capital assets : Statistics of.

As has already been mentioned in connection with capital account, it is important that records should be kept of the principal capital assets of a railway administration, and it is desirable that any statistical data prepared from such records should give an idea of the condition and, if possible, the value of such assets. The greater number of the British Colonial railways recognise this, and give full particulars of the mileage owned and operated and the accessories and equipment used in connection with such operations. The amount of detail given varies with almost every administration, but an analysis of the various statements furnished appears to indicate the desirability of compiling periodically the following information :

Permanent Way and Accessories.

General Statement, showing cost, length, highest point, steepest gradient, radius of sharpest curve, ruling gradient when fully compensated for curves, and average cost per mile of each line (excluding general workshops, general offices, and rolling stock).

Mileage Owned. — Statement showing separately the mileage of single, double, and treble track, and of sidings, also the equivalents in single track mileage for each section of the line.

Average Mileage Operated. — This information is required in connection with the preparation of other statistics.

Rails in Track. — Statement showing for each section the mileage of rails of each class according to weight, length, and date when laid.

Sleepers. — Statement showing for each section the mileage of each class of sleepers, the number laid to the mile, sizes, and ages.

Rail Fastenings. — Statement showing mileage of each type and ages.

Ballast. — Statements showing the mileage of each line according to the nature, depth, and width of the ballast used.

Bridges. — Dimensions, capacity, and cost on each section.

Reservoirs and Dams. — Particulars of capacity, description, number, site, and cost of construction for each section.

Pumping Plant. — Particulars of and cost for each section.

Coaling Plant. — Particulars of and cost for each section.

Station and other Buildings used for Railway Purposes. — Particulars for each section, under classes, giving cost.

Signalling Appliances. — Particulars for each section, under classes, giving cost.

Telegraph Lines and Instruments. — Particulars for each section, under classes, giving cost.

Land acquired for Railway Purposes. — Under sections, giving also cost and dimensions.

Equipment (Engines and Rolling Stock).

Locomotives, Particulars of. — Giving under separate types the following information :

Number of each type, tractive power, average weight (engine and tender in working trim), average cost per locomotive, dates when placed in traffic, condition, number of obsolete engines on hand. (Such statement should show against each type the additions and reductions during the period covered and particulars of any conversions. For any engines which have gone out of service the mileage run to date of condemnation should be stated for each class.)

Coaching Stock, Particulars of. — Giving for each description the number of vehicles, average age, average seating capacity, average tare, average cost. (Similar information as in the case of locomotives should be given as to additions and reductions, conversions, and mileage run by vehicles taken out of traffic.)

Goods Stock. — Similar particulars to those set out above for coaching stock (including average load capacity and average tare).

Workshops and other Plant and Machinery, Particulars of. — Giving description, age, and cost of plant owned; also of any additions or reductions during the period covered.

It is particularly important that, either in the above statements or in special statements, the condition of the equipment should be periodically brought under review. It is not sufficient indication of the actual position to show that there are so many engines and so many cars, unless the proportion or numbers in good, indifferent, or bad condition is also stated.

Statements of this nature (especially where condition and cost or value is given) exercise a salutary influence in securing that there shall be no long continuance of deterioration of capital assets, without the proper adjustments being made in capital account, or the assets being again placed in serviceable condition at the expense of working charges.

d) Statistics of the Volume and Character of the Traffic Carried.

Passengers: number and revenue.

Most railways give statistics of the numbers of passengers carried (usually also of the numbers availing themselves of each class of accomodation provided) and the revenue earned for their transport. Where the railway connects with the lines of other administrations, separate records are as a rule kept of the numbers and earnings in respect of the different classes of " through " (*i. e.* foreign) passengers exchanged with such other lines. Often also separate records are kept of the " up " and " down " passenger traffic.

The necessity for such statistics is self-evident. They enable those directing the services to gauge the public demand for facilities of different classes, and they afford information as to the probable financial and other effects of alterations in the scales of fares, in the types of vehicles used, and of any acceleration or increase of train service, etc.

To what extent particulars shall be kept will of course depend on the magnitude of the traffic carried. Some of the railways in the British Colonies keep statistics of passenger numbers under seven or eight heads, whilst others keep them all under one general head. The only rule which seems to admit of general application is that wherever there is a very considerable difference in the rates charged for conveyance of separate classes, it is advisable to keep separate records of the volume of traffic and earnings under each.

Luggage and parcels.

Luggage and parcels are usually carried by passenger trains, and in order that the earnings of the coaching service as distinct from the goods service may be ascertained it is desirable to keep separate records of the weight of such traffic for comparison

with the earnings. In many cases, separate records are kept of luggage and of parcels, and this information is sometimes found of particular value in connection with the arrangement of train services and the fixing or modification of luggage or parcels rates.

Other passenger train traffic.

Where mails, or such commodities as milk, are usually carried in large quantities by passenger trains, it may be necessary to keep a separate record of the weight and earnings under a special sub-head, but in the majority of cases all that would seem to be required is to have a general head under which miscellaneous revenue of passenger trains would be recorded with a view to arriving readily at the total earnings of such trains.

Goods and minerals.

What has been said with regard to coaching traffic, applies equally to traffic carried by goods trains or by goods vehicles on " mixed " trains. It is essential to efficient management and control that separate records should be kept of the tonnage of the most important commodities carried. If, against the tonnage of such commodities, the revenue earned can also be given the statements become still more valuable.

Traffic : direction of.

The importance of a distinction in the records between " through " and " local " traffic, and between traffic carried " up " or " down, " or " north " or " south " or " east " or " west " (as the case may be) of course varies with local circumstances, but in cases where the heavy traffic is in one direction, it is of undoubted value to have separate figures for the traffic in the two directions. Where there is the element of competition with other railways, it may be necessary or desirable to show separately the quantities and earnings of goods consigned to or from the areas where such competition is felt.

Commodities carried : classification of.

To suggest for general adoption by all administrations a detailed list of commodities, so that the tonnage of each carried might be stated in a uniform manner would no doubt be futile at the present time, but the writer would commend to the notice of those interested in the subject the general heads under which commodity statistics are prepared by all railways in the United States of America. The advantages in the matter of comparison of railway statistics if these or similar heads were adopted generally by railway administrations will be readily seen.

1° Products of agriculture;
2° Products of animals;
3° Products of mines;
4° Products of forests;
5° Manufacture and miscellaneous.

In the records of the Administration with which the writer is connected, the tonnage of and earnings on coal traffic (which in point of tonnage represents more than

*

one half of the traffic) are shown under a separate head, entirely distinct from the figures of goods traffic and earnings (which latter include all minerals other than coal). While this practice may not be entirely suitable for other administrations, it would appear to be a matter worthy of consideration whether the adoption in railway accounts of a separate head of earnings for "Mineral Traffic" would not be of general advantage.

Another distinction that should be reflected in any tonnage statements is that between public traffic and railway service traffic.

c) Unit Statistics as applied to Volume of Traffic Carried, Traffic Earnings and Utilisation of Rolling Stock.

Statistical units.

To admit of the ready grasp of the meaning of figures showing the volume and earnings of passenger and freight traffic, as well as the expenditure connected with railway working, railway managers have long been in the habit of expressing the recorded results in terms of some unit, as an average or a percentage. As is natural, most railway units take into account the element of distance as well as that of weight or number. Thus we have units based on distance and

Equipment used	Train miles. Engine miles. Vehicle miles.
Number	... Passenger unit miles.
Weight	... Ton miles.

Train mileage.

An idea of the actual services performed in connection with the transportation of traffic is given by statistics of the train mileage run, but such information requires to be supplemented by other statistics, and by a general knowledge of working conditions before it can be put to much practical use. Train mileage figures are usually given for each of the two main divisions of traffic, *viz.*, coaching and goods, but in the case of large administrations the train mileage is subdivided into further classes. Under coaching train mileage, for instance, some administrations show separately the train mileage of fast and slow passenger trains, and the mileage of excursion trains. The extent to which subdivision is necessary depends, of course, on the individual requirements of each administration. The basis for division is indicated in most cases by some marked difference in the services rendered, or in differences in the expense of running particular classes of trains.

Most British Colonial Railway administrations make extensive use of the unit of train mileage in their records of operation. Usually the earnings, as a whole, are worked out per train mile ("up" and "down") for *a*) passenger trains and *b*) goods trains, but in some cases only, the average earnings per train mile are given without any distinction being drawn between the two services. Needless to say, the latter

information, while giving a general figure of considerable value, is inadequate except for small administrations. Where the train mile earnings for coaching traffic are shown regularly under classes, a valuable indication is given as to the necessity or otherwise for adjustment of the train service, or of the scale of fares. Where the average earnings per train mile show a constant downward tendency, one might be obliged to think of cutting down the service.

Similarly with the goods and mineral train services, the earnings per train mile constitute a valuable record for purposes of control.

Passenger miles and ton miles.

The most comprehensive measure of earnings and services rendered is afforded by statistics of passenger unit mileage and traffic ton mileage. Such unit mileages in themselves express the actual amount of the work involved in the transportation of persons and material almost as clearly as a statement of the energy required to lift a certain weight is expressed in the physical sciences by the number of " foot-pounds " that is, the weight of the material multiplied by the number of feet it is to be raised. Theoretically we have in passenger unit and ton mileage statistics, what is perhaps the most satisfactory common measure of railway work which could be devised. While a train or vehicle, and a train mile or a vehicle mile, may and does differ on one administration from the same unit on another administration (or even on the same administration at different dates) the service of moving a passenger or ton of goods one mile affords a basis for a more accurate comparison, whether such comparison is with another administration or not. Such figures are, however (as has been already pointed out) of very limited practical value unless taken in conjunction with other statistics of operation — by themselves they are often positively misleading.

To a considerable and increasing extent, passenger mile and ton mile figures are prepared by British Colonial Railway administrations. Some prepare two sets of ton mile figures, one giving for both passenger and goods traffic the " gross " ton mileage (*i. e.* including the ton mileage of the passenger and goods vehicles themselves as well as of their contents) and the traffic ton mileage. The gross ton mileage is a good index of the physical work performed, and the information affords a satisfactory basis for division of certain classes of expenditure between sections or different services, such, for instance, as the division of certain *general* expenditure between passenger and goods services. Where gross ton mileage is taken out, the weight of passengers, live stock, etc., is in the British Colonies generally arrived at by multiplying the numbers carried by average (estimated) weights of passengers, etc.

Zone statistics

Where, by reason of the cost or otherwise, ton-mile figures cannot be prepared, statements of the numbers of passengers and tonnage of goods, according to the distance carried in zones, say :

From 1 to 10 miles,

From 10 to 25 miles.
— 25 to 50 —
— 50 to 100 —
— 100 to 150 —

and so on, giving the average earnings per ton for each zone, and for different commodities, will be found to be almost as valuable as the average earnings per passenger unit or per ton mile. For purposes of rate making or adjustment, such figures are — in the opinion of the writer — even more valuable, as it is possible from the statements to gauge at once the financial results of a reduction in rates for long or short distance traffic in any of the classes for which the records are kept.

Average haul.

With the figures of passenger unit mileage and ton mileage are usually given particulars of the "average distance haul" for passengers and for goods — information which is not nearly as valuable as the statistics of the traffic under zones to which reference is made in the preceding paragraph.

As a general indication of the rise or fall in earning power of their lines, most British Colonial Railway administrations give the earnings for passengers and freight per mile of line. Such information is more valuable when taken out for the different sections of the line, so as to reflect the development of particular districts. Such figures are occasionally valuable when projects are under consideration for the construction of new lines in districts where the conditions are similar.

Train loads.

Some of the uses of engine, train, and vehicle mileage statistics, have already been referred to, but perhaps the most important direction in which such figures are useful is in securing the efficient loading of the rolling stock, and also in getting the maximum amount of work out of such stock. The latter should perhaps come first, for the expense of providing engines and rolling stock represents a large proportion of railway capital expenditure; how large the proportion is of the whole must ultimately depend on the efficiency with which the engines and rolling stock are utilised. To get the maximum amount of work out of a given quantity of rolling stock means that fixed charges, such as interest on capital expenditure for rolling stock, are kept down to the lowest possible figure.

The great thing is to keep the stock employed to the fullest possible extent in hauling traffic; never to incur light mileage where it can be avoided, and to keep the stock moving and earning money. The minimum of cost cannot be secured unless good engine loads are arranged with trucks loaded as nearly as may be to their full capacity, and passenger cars to the full extent which the accommodation permits.

So far as the use of such statistics more directly bears on the efficiency of the stock used, the principles of application will be dealt with later, but the importance of taking out the average number of passengers and the average number of tons of

freight carried in each train and in each loaded car or truck should be mentioned here. Most British Colonial Railways take out such figures, but the value of the information as an aid to operation would be much greater were the figures given separately for each section, for up and down traffic, and for traffic between specially important points on the system.

Efficiency and utilisation of engines and rolling stock.

As already mentioned, a material factor in economical working is to keep equipment employed on remunerative work. To maintain a check on this, records must be kept of the mileage run by engines and vehicles.

Particulars of the train mileage actually run is kept by all railways; there is, however, no generally accepted classification of such mileage. Most administrations give separately

Passenger train mileage;
Goods train mileage;
Mixed train mileage;

but it is desirable also to supplement this by giving the following particulars, at least, of the train service :

Other revenue train mileage;
Work train mileage;

as well as particulars of other engine mileage, *viz.* :

Assisting (banking, etc.), engines;
Light engines;
Shunting engines.

The latter should be calculated on some uniform basis per hour, preferably six miles, so as to be in accord with the practice in England, North America, and other countries.

The mileage run under each of the above classes, taken out regularly under sections, is of much use if any increases on the figures of previous periods are carefully scrutinised in conjuction with other figures, such as those of the average load per train and the average earnings per train mile. Where these returns are supplemented by statements showing the percentages of each class to the total mileage run, any increase in the proportion of light mileage is at once brought into relief as a matter calling for enquiry. Again, the average mileage run under these heads by the engines in service during the particular period under review as compared with past periods, is a useful indication of whether the greatest possible work is being got out of the stock.

Some (but very few) administrations give also the average gross ton mileage hauled per engine and a comparison with the maximum ton mileage which could have been hauled by each type. Such assumed maximum ton mileage is, of course, a figure

based on ideal conditions, but affords a comparison more or less accurate between possible and actual efficiency.

Nearly all administrations keep for each locomotive a record of the mileage run by it each week or month throughout its running life. The information is of value in arriving at the rate of depreciation of engine stock.

Vehicle mileage and loads.

The average vehicle mileage run by passenger and goods stock is another figure of considerable value as indicating the extent to which the stock is being employed, while the average number of passengers per coach, or the average load per truck in the case of freight, gives information as to the efficiency of the loading, which is of the greatest possible value for comparative purposes. Where loads are substantially and habitually below the carrying capacity of the vehicles the returns will indicate a direction in which enquiry is called for.

Of course any such statistics lose part of their value unless they are taken out separately for sections of the line where the traffic conditions are exceptional; for instance, if one of the sections has very heavy mineral traffic carried in special trucks of large capacity, it is obviously desirable to isolate the figures for that particular section for special consideration.

A few administrations take out figures giving a comparison between the average loads of loaded cars under classes (as well as for all classes as a whole) and place against each class the average possible load. This gives a further general idea of the efficiency of the loading.

As the value of most statistics, and especially those relating to the actual working of traffic, largely depends upon the promptitude with which they can be made available, most railway systems apply quite a number of other checks on working long before some of the more elaborate returns referred to can be completed. In the early part of this paper, reference has been made to the special value of such " temporary " statistics to those entrusted with the operation and management of a railway system. The records of Colonial railways show that considerable attention and importance is attached to daily returns from stations, showing the loading of trains (both passenger and goods) and trucks, and the punctuality and average speed of trains; bad loading and delays in train service are promptly brought to notice and remedied, if possible, before they have time seriously to affect the results of working or give rise to public complaint, as the case may be.

Many uses and combinations (1) of figures referred to above can be and are made by individual administrations, with which it is not possible to deal in a short paper, but a sufficiently clear idea of general methods and principles has been given, and I will now pass to the principles of such statistics as relate more closely to railway working expenditure and the staff employed and material used in operation.

---

(1) As instances the following may be mentioned : train miles per engine hour; vehicle miles per train mile; ton miles per vehicle mile.

f) Statistics of Cost of Operation.

In anticipation of that portion of the report which deals with the uniform classification of railway working expenditure, I have already referred to the importance of keeping expenditure records according to services rendered, rather than by departments and of subdividing such heads of expenditure according to proximity of services to the actual conveyance of traffic.

It is only when we come to the consideration of statistics of cost of operation and the principles on which they are based, that the full importance of a good arrangement of expenditure heads is fully demonstrated. Where such a classification exists, the operating officers can be readily supplied at very small cost with information as to the economy and efficiency, or otherwise, of general working. Without a proper classification, results are either obscurred or have to be specially taken out, often at great expense.

With railway working expenditure, as with everything else, the larger the figures are the greater is the difficulty of grasping their significance. Where the only record is the total working expenditure month by month or year by year, comparisons as to the results achieved can only be made if one is satisfied that the conditions during the different periods were practically unchanged. Whether increases or decreases are shown as between one period and another, enquiry as to the causes which gave rise to them is naturally suggested. An increase (even with a decrease in the train mileage run) does not necessarily imply bad working; it may have resulted in a large increase in the net surplus available, and be partially or wholly justified it may be due to the operation of an increased mileage of lines, or to increased facilities being given in the matter of train services, to an increase in the volume of traffic handled, or to some necessary adjustment of rates of pay of the railway staff.

Similarly, a falling off in the expenditure may be due to a reduction in the services rendered or to other causes, and may or may not be a matter for congratulation.

To make the position clear to the responsible officers of an administration it is essential, firstly, that the accounts should be in such a form as will be helpful and, secondly, that the "unit" or other statistics prepared should be appropriate and sufficiently complete to admit of correct deductions being arrived at without much trouble.

Whatever the heads of expenditure are, it is requisite that they should separate expenditure in connection with railway working from expenditure on services of a subsidiary or independent character. For the purpose of setting out the further development of statistics, it will be assumed that they distinguish clearly between expenditure for

1° Maintenance of way and works,
2° Maintenance of equipment (engines and rolling stock),
3° Transportation (*i. e.* running expenses),

4° Traffic,
5° General and other charges,

this being a division easy to follow and one to wich quite a good number of the accounts kept by British Colonial railway administrations could with very few alterations be made to conform.

Unit statistics of cost.

The expenditure under each head, sub-head, and item is in most railways also reduced to " averages per unit," in the same manner as the earnings are worked out according to different units. The units used for expenditure are the same as those used for earnings; that is, the expenditure for each head may be shown :

Per open mile.
Per mile of single track.
Per train mile.
Per vehicle mile.
Per gross ton mile.
Per revenue ton mile.
Per passenger unit mile.

The resulting figures are placed alongside the corresponding figures of earnings for the same units, and afford a general view (when compared with previous periods) of the results of operation.

So far as British Colonial railways are concerned, the most generally used unit for general comparisons is the " train mile ".

Most administrations also show the percentage of each head of expenditure to

a) Earnings,
b) Total Expenditure,

a statement which is of considerable value to the administration in bringing to notice any radical variations in the proportions of the expenses for particular services at different periods.

Statistics of staff employed.

An instructive and useful general statement (compiled by several of the systems which have furnished information) shows for each separate branch of the railway service under specified grades the number of staff employed and their remuneration for the period covered, as well as similar information for previous periods for purposes of comparison. Any increases or decreases are also shown and the average number, average remuneration, and cost for each grade per open mile and per train mile. Where comparisons are instituted with the figures of other administrations (which should be possible in the case of government railways or railways under the same control) such statements bring out the merits or demerits of any particular organisation, for in almost every administration by far the larger portion of the cost of working is represented by personal emoluments.

Sectional figures of expenditure.

Before passing on to statistics applying more particularly to the expenditure and working of individual departments or branches of the railway service, attention is drawn to the value of records showing separately the expenditure of the different branches or sections of a railway as a means of securing efficient and economical working. In quite a number of colonial railways (including the different systems in South Africa) such sectional records or statistics are regularly prepared. A specimen of the forms on which they are prepared on the Central South African Railways is reproduced (1) in order to give an idea of what is meant. Blue prints of the completed forms are sent regularly to all the principal operating and other officials who have it in their power to influence expenditure. They are thus enabled to compare the working of one line with another — the lines for which they are responsible with those of their colleagues — and a spirit of friendly rivalry is induced which has been found is actual practice to result in large savings in expenditure. It will be seen that the expenditure for each section is given in totals and sub-totals as well as

per track mile,
per train mile,
percentage of earnings,
percentage of total expenditure.

The amount regularly set aside for the renewals of capital assets of each section is shown separately in all cases, as the provision made for depreciation is a matter settled by the chief executive authority and is not controlled by the operating officials in any way.

In order to arrive at the working expenses on particular sections of the lines, certain items of expenditure common to several or all sections have of course to be *pro-rated* or distributed; it is not possible to formulate any general rules for such distribution which could be applied to railways generally. The cost of *Maintenance of Way and Works* can, as a rule, be accurately allocated to sections (any engineering superintendence being distributed as a percentage on the whole). That for *Maintenance of Locomotives*, including superintendence, can usually be apportioned between sections on the basis of the engine mileage run on each. Similarly, the cost of *Maintenance of Passenger and Goods Vehicles* can be fairly apportioned according to the vehicle mileage run on each section by passenger or goods vehicles.

Transportation Running Expenses can usually be charged to the actual sections in which the expenditure was incurred, and any balance distributed pro rata to the train mileage run on the different sections. Expenses at large terminal stations sometimes require special treatment and distribution over the sections benefited.

(1) See part 5.

Traffic Expenses (*Stations, etc.*) are to a large extent capable of allocation to actual sections, and what remains can be fairly distributed on the basis of train mileage.

General and other charges can as a rule be charged out to sections as a percentage on other expenditure.

Apart from the use of sectional figures as an aid to operation, they are often found useful when considering the claims of particular districts for increased facilities or additional lines. Notwithstanding the fact that they are based to some extent on averages, the writer believes that with care they can be made to reflect accurately the actual position and effect savings in working, out of all proportion to the cost of their preparation.

Division of expenditure between "passenger" and "goods" services.

It might be expected that, as they have largely followed English methods and practices, few railways in the British Colonies would take out separate figures of the cost of conducting the passenger and goods services and the cost per passenger per mile and per ton mile, but this is not the case. Such figures are regularly taken out by most of the larger administrations and periodically by some of the smaller ones. Unfortunately, there is no uniform basis for arriving at such figures, which must depend for their accuracy on the degree of precision with which expenditure can be assigned to the passenger or goods services.

There can be little doubt that with the exercise of care in their preparation, separate statistics of the cost of hauling passengers and goods afford most valuable information to those directing the operation of a railway. Such figures should, in the opinion of the writer, be regarded as approximate only and as of value for administrative rather than for operating purposes; ton mile costs for instance have and should have great value as one (but *only* as one) of the factors to be taken into consideration in fixing rates; for if they are reasonably accurate they afford a better measure of the value of the services rendered than any other unit. Even as regards operation, they give in one figure more complete information as to the average cost of transportation on particular lines or sections than can be obtained otherwise, and by long continued adherence to the same method of compilation, comparative figures of undoubted value are obtained since they represent in crystallized form practically all the elements of cost. The preparation of such statistics entails considerable expense, and the question whether the advantages obtained are such as to warrant such an expense is one which can be decided only by the administrations concerned.

Ton mile statistics.

The whole question of the desirability of taking out ton mile statistics is of a controversial character, and as it is impossible in this paper to discuss adequately the pros and cons thereof, I propose simply to offer some suggestions as to a method of apportioning expenditure between the passenger and goods services, in order to obtain the benefit of the criticisms of those present and, if possible, lay the foundations of some method which will be capable of general application.

All working expenditure incurred directly in connection with passenger or goods service to be allocated specially as either " passengers " or " goods," as the case may be. So far as expenditure is common to the two heads, the basis of division between " passengers " and " goods " to be as follows :

Permanent Way and Works Maintenance distributed pro rata to train mileage of passenger and goods trains.
Locomotives Maintenance distributed pro rata to passenger train mileage and goods train mileage.
Coaching Stock Maintenance to be allocated to " Passengers ".
Goods Stock Maintenance to be allocated to " Goods ".
Transportation (Running Expenses) to be allocated to passengers and goods in proportion to mileage run by passenger and goods vehicles.
Traffic Expenses to be apportioned on basis of passenger and goods train mileage.
General Charges to be apportioned as a percentage on total other expenditure.

In the case of administrations which are in the habit of taking out the gross ton mileage hauled (*i. e.* the total ton mileage including that of the vehicles containing the traffic) it is possible that the above suggestions may not be the best possible, but as against this it has to be borne in mind that comparatively few administrations do take out figures of gross ton mileage, and what is sought is some general scheme which can be applied to most administrations without imposing on them the necessity of getting out additional statistics.

Attention is now directed to statistics specially relating to the working of individual branches of the railway service.

Maintenance of Way and Works.

Maintenance of way, works, and stations.

Most administrations prepare statements showing under each head, sub-head, and item of expenditure the cost of maintenance " per mile of line maintained " giving comparisons with the figures for previous periods. As a rule, the mileage on which the costs are worked out is " route " or " point to point " mileage, but in many cases the figures are also given " per mile of single track including sidings "; the latter is the more satisfactory. The expenditure under each item is usually also given per train mile and, in the case of administrations which are in the habit of taking out gross ton mileage, per 1,000 gross ton miles. The percentage of each of the different items to the total expenditure for Maintenance of Way and Works is also usually given.

All of these figures are useful; where it is not considered necessary to take out so

much detail, it would seem to be advantageous to give information, at any rate, as to the costs

a) per mile of single track,
b) per total train mile.

Statements showing by districts the cost of maintenance per mile of single track, under heads and sub-heads, and statements showing for each grade of the staff the average number employed (and the cost) per mile of single track for each section will be found, perhaps, as important for purposes of general control and comparison as any statements usually got out in connection with Maintenance of Way and Works.

So far as the permanent way itself is concerned, quite a number of other statistics are got out by different administrations with a view to ensuring that the capital assets of the administrations are maintained in good condition and that economies in working are not effected at the expense of Capital Account; amongst them may be mentioned the following which are regularly taken out by a number of railways amongst those furnishing their information for this paper :

Ballast. — Statistics of the number of cubic feet of different kinds of ballast put into the track, giving the cost per hundred cubic feet (by districts).

Sleepers renewed. — Statistics of the number of sleepers of different kinds taken out of the track and replaced, giving ages of the sleepers renewed (by district).

Rails relaid. — Statistics of the number of rails taken out of the track and replaced, giving weights of rails of different sections and values (by districts).

Rails found broken. — Statistics of broken rails discovered, giving mileage in each case and particulars and cause of break.

Relaying. — Particulars of cost of relaying work carried out in each district, showing separately expenditure for wages and material.

Extraordinary expenditure for Maintenance. — Statements of special work entailed by slips and washaways (by districts).

Bridges. — Statistics of the cost of maintenance of each of the principal bridges in each district.

Stations and Buildings. — Particulars of the cost of maintenance of each of the principal buildings on the system (by districts).

Maintenance of equipment.

Particulars of the statistics commonly prepared as to the maintenance of equipment by railways in the British colonies are given below.

Maintenance of Engines.

Cost is usually worked out per train mile and per engine mile. (In many cases also the average cost of maintenance per 1,000 gross ton miles is given.)

Statistics are also usually kept of the mileage run by each engine, month by month, and the actual cost for repairs of each engine.

Note. — If the cost of repairs is made to include running repairs (which unfortunately is not usually the case) it affords important information as to the relative expensiveness of maintenance of engines of different types.

Figures of the engine mileage run by each engine are sometimes kept and are valuable in arriving at the proper provision to be made out of working expenses for replacement of particular types of engines.

As a check on working expenses and to ensure the maintenance of a proper standard, many British Colonial administrations prepare periodical statistics of the number of engines repaired and overhauled, giving particulars under classes of the repairs effected. The particulars of such repairs vary considerably for different administrations, but the following particulars are usually given :

Total passed through shops;
Built : new;
Re-erected;
Thoroughly overhauled;
Heavy repairs;
Light repairs;
Painted and varnished;
Touched up.

Special statistics of locomotive boilers repaired are usually kept.

Passenger Vehicles : Maintenance.

The expenditure for maintenance of passenger vehicles is usually reduced to statistics giving the average cost per passenger train mile and per 1,000 passenger vehicle miles. As in the case of locomotives, statistics are usually kept of the number of passenger vehicles of each class repaired and overhauled during the year, classifying the repairs under appropriate heads, giving for each the cost and the average cost per vehicle.

Goods Stock : Maintenance.

Similar statistics to those kept in the case of passenger stock are usually prepared for goods vehicles. In order to get at the relative merits of different classes of trucks, much importance is usually attached to keeping separate records for the different types of trucks, especially where there is a great divergence in such types (as in the case of administrations carrying very heavy mineral traffic in specially designed and constructed trucks of large capacity).

Transportation (Running) Expenses.

Transportation: running expenses.

Since running expenses usually constitute a large proportion of railway working expenditure, it is not surprising that voluminous statistics are kept by most administrations in connection with this particular service. The largest element in running expenses is usually the remuneration of the drivers and firemen and other trained staff, and special statistics are, as a rule, prepared to show the cost per train mile for such services, the number of staff engaged, the average mileage run per man — advantage being taken of such returns to compare the results achieved on different sections of the line. In addition to the detailed statistics showing the cost of running per train mile and per engine mile, many administrations secure an additional check by taking out the average cost per 1,000 gross ton miles or per 1,000 vehicle miles for the whole system as well as for districts. As a rule, regular comparisons are also periodically instituted between the numbers of the running staff, their average pay per man, and the average cost for each grade per train mile and per engine mile.

Another effective check on the expenditure for this service which appears to be fairly generally exercised is the compilation of statistics of the working of each engine shed on the system giving the shed costs in great detail, and the average cost per engine mile, worked out on the mileage run by engines from each shed.

Most administrations agree in taking out in detail statistics of the coal consumption per train mile and per engine mile.

Where considerable expenditure is incurred for handling coal or pumping water, it is a common practice for administrations to take out, for each coaling and pumping station, the costs per ton and per 1,000 gallons, respectively. Comparisons between such stations are instituted thereafter for the purpose of bringing to light any excessive cost (where such exists) which may admit of reduction, either by the provision of more economical appliances or by the reduction of labour costs in other ways.

Oil consumption is usually worked out separately for engines and vehicles per engine mile and per 1,000 vehicle miles, respectively. Regular comparisons are also instituted with lubricating costs at other times and on other lines.

Reference has already been made in the early part of this paper to the importance of certain checks exercised with a view to ensuring the proper loading of trains and vehicles, and to the necessity of keeping a check on light engine and vehicle mileage.

A few administrations take out regularly for each type of engine, statistics of the actual work done (expressed in ton miles) and the cost for each of the principal items making up running expenditure so as to afford a more accurate comparison of the relative efficiency of the different types in use. Such statistics are of an expensive nature to prepare and, as they are not generally compiled, it does not seem to be necessary to do more than observe that they have been found of considerable

value by administrations whose operations are of such a magnitude as to warrant the expense of instituting such special enquiries. On smaller railway systems, operating officials are able to arrive at a judgment sufficiently accurate for all practical purposes without statistics of this nature.

Traffic Expenses.

Traffic expenses.

As a rule, traffic expenses are worked out per train mile. In some cases, the expenditure on each item is shown as a percentage of the traffic earnings. As by far the greater portion of traffic expenses consists of the cost of stations and station staff, special statistics and returns are usually got out showing for each station the number of staff, their pay, and other expenses. Alongside these figures are usually placed particulars of the number of passenger bookings and the revenue and tonnage of goods traffic, in and out, so as to afford a ready comparison between station cost and station revenue. For the larger goods terminals, statements are taken out by many administrations in which the costs of handling, etc., are shown worked out on the tonnage of goods handled.

General Charges.

General and other charges

Most administrations prepare statements showing the cost of these services per train mile, per cent on total earnings, and per cent of total expenditure.

Such general charges are, as a rule, more of the nature of fixed charges than other items of railway expenditure and vary less directly with increases or decreases in the traffic handled. It is necessary, therefore, to scrutinise each individual item separately, and there are few statistics which can with advantage be generally employed to effect comparisons between administrations. With regard to accounting work, however (which is usually embraced under the head of General Charges), certain comparisons have in the past been made between expenditure for this service by the different South African railway administrations on the basis of the cost of different sections of the work, expressed as a percentage of the revenue collected or the expenditure for railway service according to the nature of the work. To effect these comparisons, it is necessary to separate the cost of accounting for (*a*) earnings and (*b*) expenditure; such a division can, it is believed, be made with sufficient accuracy to afford a basis for instituting a very useful comparison, especially so far as the cost of accounting for railway expenditure is concerned.

g) Statistics relating to Indirect and Subsidiary Services.

INDIRECT SERVICES.

By indirect services are meant the branches of the railway service which do not fall within the scope of any of those previously enumerated but exist for the benefit

of the administration as a whole. The most important of these are the Stores Department and Workshops.

Stores department

As a rule, the service of maintaining an adequate supply of stores and material required in railway working is delegated to a special department whose duty it is to keep records under suitable heads of quantities and values of material in stock and any receipts and issues. Most of the returns furnished by the British Colonial railway administrations as to the classes and values of such stores are merely classified statements from the Stock Ledgers. Statistics showing the quantities and, values of material handled at different stores depots are, however, prepared by some administrations in which the stores expenses are stated as a percentage on the value of such receipts and issues. This information is an effective check if comparisons are given with earlier periods, and in those cases where expenditure of the Stores Department is charged out to other departments as a percentage on the value of the stores issued, the preparation of regular monthly or quarterly returns showing what the service is actually costing per cent, ensures that the distribution of the expenditure shall respond readily to any change in methods of working and cost.

Workshops.

The Workshops of most railways are under the control of the Locomotive Department (or in cases of railways which have adopted American methods of organisation, the Chief Mechanical Engineer). In some cases, there are separate workshops for the engineering and other departments, but modern practice seems to take rather in the direction of centralising work and having it done in the main wokshops, *viz.*, under the control of the Locomotive Superintendent or the Chief Mechanical Engineer, as the case may be. Whatever practice is adopted, the magnitude of the Workshops expenditure of a railway administration is usually such as to necessitate the preparation of regular returns and statistics with a view either to effecting comparisons with the cost of getting the work done elsewhere, the cost on other railway administrations, or the cost of performing similar work during some previous period. Broadly, the work done in the shops may be devided into two main classes :

1° Work in connection with maintenance of equipment.
2° Manufacturing and other work done for other branches of the railway service or for the public.

Reference has already been made to the statistics usually prepared in regard to the maintenance of locomotives and passenger and goods stock. So far as manufacturing work is concerned, most administrations seem to rely on systems of cost accounting for an indication as to whether the work is being done economically or not. In the one or two cases where methods of cost accounting have been developed to a greater extent than is customary amongst railway administrations regular statistics are taken out of the cost of manufacturing particular articles or spare

parts, thus admitting of comparisons being instituted between the cost of carrying out any particular class of work at different times. Apart from the value of such records as a check on uneconomical working, statistics of this nature are found to be exceedingly useful as a guide in preparing estimates of the cost of carrying out any work and also in connection with the development of any system of remuneration by piece-work. Other statistics that have apparently been found of use in Workshops control are statements of expenditure for each of the different shops, showing under separate items the charges for shop superintendence, chargemen, artizans, labourers, upkeep of machinery, power, light, heating, etc., and the percentage of such different items to the total expenditure of each shop. Where there is a foundry, or where an administration makes or rolls its own steel or carries on any separate industry of a similar nature, the ordinary commercial practice of taking out figures showing the output and the cost per ton or per other unit is usually followed with advantage. This observation may be regarded as applying also to the electric light and power branch of a railway where statistics are almost invariably taken out of the expenditure for generating and distribution per Board of Trade unit.

SUBSIDIARY SERVICES.

Quite a number of railways perform services which are distinct from railway working although they are, as a rule, closely connected therewith. So far as the British Colonial railways are concerned, the most important of such subsidiary services are the cartage of traffic to and from stations, the provision of meals and hotel accommodation to passengers (in many cases to the general public also) and the running of steamship services in connection with the railways. Where such services are conducted, the statistics got out and the checks applied to expenditure are, as a rule, of a slightly different nature to those pertaining to the railwy service proper.

The cost of cartage service is usually taken out under suitable heads for each station and statistics prepared showing cost per ton handled.

Catering and hotel services are usually reduced to such statistics as are kept by those engaged in the business of catering outside the railway service. A useful statement which has been furnished to me gives a comparison for different periods between the earnings, expenditure, net earnings, and percentage of profit at each of the station refreshment rooms, showing separately receipts and expenditure for meals and for alcoholic and other liquors, tobacco, cigars, cigarettes, etc. For dining-cars the earnings, expenditure, and net earnings for each car are shown separately and the average cost of meals served.

As regards statistics of steamship services, these usually follow the same general lines as are adopted by steamship companies.

h) Other Miscellaneous Statistics.

Staff: social condition.

Apart from the statements showing the number and remuneration and average pay of Staff in individual departments already referred to, it is quite usual on Government railways to furnish a considerable amount of information as to the condition of the Staff. The value of such information is certainly great to the political economist, and it is occasionally useful to those directing the operation of a line. The following statements among others are prepared by some of the Colonial railways :

Statistics of social condition of Staff showing nationality, age, whether married or single, average emoluments per day or per month or per annum for each grade, giving comparisons with previous years.

Statistics showing for each grade, the number of Staff employed at the beginning of the period, appointments made during the period, wastage during the period (showing separately resignations, dismissals, services dispensed with, deaths, and transfers), total remaining at the end of the period.

(The figures of wastage worked out as a percentage on the Staff employed will be found of interest and use in connection with Staff arrangements, especially in a large administration where the Staff is sufficiently numerous to allow of the operation of the law of average.)

Where pension and other institutions exist for the benefit of the Staff statistical information is usually compiled setting out the extent to which the privileges are availed of.

Other social statistics.

In practically all British Colonies, railways are required to render returns of accidents arising through the operation of railways. The form in which such returns are prepared varies almost with each Colonial Administration, but the best practice shows separately the number of :

a) Accidents to passengers;
b) Accidents to the general public other than passengers;
c) Railway employees.

For each class, the extent of the injuries sustained is shown, *e. g.* a distinction is made between those killed and those injured. Further, the accidents are classified as far as possible according to their nature and causes.

PART 3.

Uniform Classification of Working Expenses.

Amongst English speaking nations and countries, there have been three successful attempts to introduce a classification of railway working expenses applying to all railways operating within the territory under which such classification has been promulgated. On each occasion, the classification has been one that has either been laid down or enforced by the Government.

The first uniform classification was that applied by Act of Parliament to English railways. This is generally admitted, even in England, to be inadequate and unsuitable, and at the present time, the question of its revision is engaging the attention of a Royal Commission, whose report will probably be available by the time the Congress meets in Berne.

The second was that applied by the Government of India to railways operating in the Indian Empire. This classification (though much more extensive) is in many respects marked by fairly close adherence to the English model.

The third is the comprehensive classification issued in the United States of America by the Inter-State Commerce Commission, and having the force of law. The last of these (as is fitting from the premier position of the United States in the matter of railway mileage) is in point of development far more complete than either the first or the second.

In considering what classification of working expenditure could be adopted for general use, one cannot fail to be influenced by the large amount of work which has been done at the instance of the Inter-State Commerce Commission in America, in settling the classification which now applies to all railways in the United States.

The principal differences between the American classification on the one side, and the English and Indian classifications on the other, are as follows :

1° In America, there is a hard and fast line drawn between
   a) The operating expenses of railways and
   b) Expenditure in connection with subsidiary operations undertaken by railways.

2° In America, the cost of maintenance of locomotives and rolling stock is kept distinct from running expenses.

3° The cost of transportation is in America kept distinct from " traffic expenses." (1)

(1) The term " Traffic expenses " is here used in the sense in which it is applied in America.

4° In America, regular provision is made for charging working expenses with the estimated depreciation of the different classes of capital assets. Expenditure for replacement of such assets is met from depreciation funds, so far as it is covered by contributions standing to the credit of such funds, any balance being charged to working expenses;

5° The American classification not only sets out item by item clearly what shall be charged to working expenses, but also indicates clearly the classes and nature of expenditure which is to be charged to Capital and other Accounts.

Comparison of various classifications.

The differences under the main heads of classification of expenditure in certain different countries are shown below :

Main Heads of Working Expenditure.

United States of America (225,000 miles).	*Great Britain* (24,000 miles).	*British India* (29,000 miles).	*Typical British Colonial Railway.*	*France* (30,000 miles).
Maintenance of Way and Structures.	Maintenance of Way and Works.	Maintenance of Way, Works and Stations.	Maintenance of Way, Works and Stations.	Maintenance of Way and Structures.
Maintenance of Equipment.	Locomotive Power.	Locomotive Power.	Locomotive Power.	Locomotive Power and Carriage and Wagon Expenses.
	Repairs and Renewals of Carriages and Wagons.	Carriage and Wagon Expenses.	Carriage and Wagon Expenses.	
Traffic Expenses.	Traffic Expenses.	Traffic Expenses.	Traffic Expenses.	Traffic Expenses.
Transportation Expenses.				
General Expenses.	General Charges.	General Charges.	General Charges.	General Administration.
	Rates and Taxes.	Steamboat Service.		
	Government Duty.	Special and Miscellaneous Expenditure.		
	Compensation.			
	Legal and Parliamentary Expenses.			
	Miscellaneous.			
	Expenditure not allocated.			

From the above tabulated statement, it will be seen that the main heads in the

American classification are intended to, and do, reflect the cost of the several main services connected with railway working, *viz.* :

American expenditure heads.

1° The maintenance of the track and its appurtenances and of the buildings utilised in connection with its operation;
2° *The Maintenance of the Engines and Rolling Stock used for the conveyance of traffic*;
3° *Expenditure incurred in obtaining traffic and in affording information as to the facilities given by lines for the conveyance of traffic*;
4° *Expenditure directly or indirectly connected with the actual conveyence of traffic : such as cost of operation of trains and stations.*
5° General expenses.

As regards heads 1° and 5°, these correspond to a large extent with heads in the classification adopted by most of the railways outside North America — that is to say Nos. 1° and 5° are at the present time practically uniform main heads of expenditure throughout the railway world.

In place of Nos. 2°, 3° and 4° most railways outside North America record their expenditure under the following main heads :

a) *Locomotive Power.* — Includes maintenance of engines (American head 2) and running expenses of engines (American head 4).
b) *Carriage and Wagon Expenses.* — Includes maintenance of rolling stock (American head 2) and running expenses of rolling stock (American head 4).
c) *Traffic Expenses.* — Includes cost of obtaining traffic (American head 3) and station and other staff (American head 4).

Uniformity of expenditure records could easily be obtained by the adoption of a classification comprising :

1° Heads common to most administrations;
2° Separate heads for all items which are treated differently by (*a*) railways in North America and (*b*) other railways.

Such a classification would embrace the following heads :

1° Maintenance of Way, Works, and Structures;

2° Maintenance of Equipment;

3° Transportation and Traffic Expenses.
  a) Running Expenses and Supplies (Locomotives and Vehicles).
  b) Station and other Traffic Staff.
  c) Cost of obtaining traffic, etc.

4° General Charges.

[In the above list Nos. 3°*a* and 3°*b* together would correspond to the head " Transportation Expenses " in the United States classification, and Nos. 2°*a* and 3°*a* together would correspond with " Locomotive Power " and " Carriage and Wagon Expenses " in the other classification.]

The weak part of such a classification is that it is a compromise, and, like most compromises, it does not entirely satisfy the requirements of those accustomed to work to either of the classifications on which it is based. To the manager of an American line, it would seem a retrograde step were the present American classification altered so as to show separately the cost of departments which do not form part of the usual organisation of an American railway, but which exist in countries which have followed English practice, *i. e.* the locomotive department (which has control of the engine-drivers, firemen, and running shed staff) and the traffic department (which has charge of station staff, guards, etc.).

On the other hand, the railway manager in other countries is accustomed to receive information as to the expenditure of each *department* of the organisation of which he has control and any rearrangement of expenditure heads which decentralises or appears to decentralise the expenditure of a particular department must have much to recommend it before securing his adherence.

So far as lucidity and arrangement go, the main heads of the American Expenditure Classification leave little to be desired, and the writer feels that no argument which he could put forward would detract from the superiority of that classification over any other that he has had the opportunity of examining. Whether the general adoption of the American Classification in its entirety would be practicable at the present time or not is a matter worthy of discussion; if not, such a compromise as that suggested above appears to the writer the only alternative to losing the advantage of being able to institute comparisons with American systems.

Only the main heads (or grand divisions) of working expenditure have been dealt with above. For small railways it is quite conceivable that no more extended classification of working expenditure would be necessary than is comprised by the main heads under discussion, *viz.* :

1° Maintenance of Way, Works, and Structures;
2° Maintenance of Equipment;
3° Transportation and Traffic Expenses;
4° General Charges.

For larger systems, however, effective control would not be possible without some subdivision of such main heads. Such further analysis might with advantage be based on the actual subdivision of the work performed, since this remains practically the same whatever changes in organisation may take place.

In the annexures to this paper (1) an attempt has been made to indicate for each main head of expenditure such sub-heads as appear generally suitable for adoption. In a third column, the process of subdivion is carried still further so as to cover the requirements of railways desirous of obtaining still more detailed information from their expenditure accounts. The classification outlined is composite, based principally on American practice with some slight alterations and additions based on South American (Buenos Ayres Great Southern), French, British, and British Colonial practice.

The proposals cover only the working expenditure of a railway, that is, the total cost of maintaining in good order and condition the capital assets of the raiway and of carrying on the business of transportation, as distinct from the cost of performing other services (described in America as " Outside Operations ") which are often performed by railways but equally often left to other agencies or put to tender.

TREATMENT OF EXPENDITURE ON " INDIRECT " SERVICES.

In connection with the matter of classification of working expenditure it is necessary specially to mention certain general services more or less directly connected with railway working such as the following :

Stores Department;
General Workshops;
Electric Light and Power Branch;
Sanitation.

If the total cost of working a railway is to be recorded under certain main heads, it is submitted that all expenditure in connection with such subsidiary services as those set out above should be taken out separately and distributed on some well considered basis over the main expenditure heads themselves, having regard to the amount of work done for each. Unless there is uniformity in regard to the treatment of such expenditure it is apparent that no effective comparison is possible between one railway and another. Absolute uniformity in the expense classifications of these separate accounts is not essential at the present time, although desirable.

Similarly, it is desirable to keep separate records of such expenditure as that on

Fire and other insurance,
Contributions to pension funds, sick funds, etc.,

and to distribute the charges over the main heads of working expenditure if the total cost under each main head is to be arrived at.

---

(1) See part 5.

OTHER MATTERS AFFECTING WORKING EXPENDITURE.

Other matters closely connected with the classification of expenditure arise out of the varying methods of providing for or accounting for

a) Maintenance, etc., of Staff Quarters, House Property, etc.;
b) Depreciation of Capital Assets;
c) Capital Expenditure and expenditure for Betterments.

In order to bring the question of the best method of treatment of such services under consideration, the following information is afforded as to the practice followed by the Central South African Railways — practice based largely on those obtaining on certain large lines in South America:

Reale state.

a) Any profit (or loss) on "Real Estate Account" is carried to net revenue account. All revenue and expenditure in connection with quarters or other structures for which the administration receives or might receive rent is carried to a separate account called "Real Estate." Such structures comprise:

Quarters let to employees and others for which rent is paid by the occupier;
Quarters let to employees and others for which rent is paid by the department;
Buildings occupied by the cartage department;
Buildings occupied by the catering department.

The revenue includes all rents and receipts for water, sanitary and other services. (Where quarters are occupied by employees rent free, the amount of the rent is charged to the departments to which the employees belong.) The Expenditure includes cost of maintenance, water supply, sanitation, rates and taxes, fire insurance, depreciation, etc.

Depreciation of capital assets.

b) Provision is made for charging working expenditure with amounts for depreciation and crediting such amounts to renewals or replacement funds until such time as it becomes necessary to renew the different assets. The following example will serve to explain the working of the different depreciation funds:

A locomotive is purchased at a cost of £5,000 on the opening of the railway, and is placed in traffic on 1. January, 1908. Its life is estimated at 20 years. Each year (in addition to the cost of *all* repairs) one-twentieth of its original cost is charged to working expenses under Locomotive Maintenance (depreciation) and credited to "Locomotive Renewals Fund." By the 31st December, 1927,

this fund will show a credit balance of twenty times £250=£5,000. The original locomotive is now worn out, its scrap value being, say, £300. It is desired to purchase a new locomotive in place of the old one, and the following adjustment is made in the books :

An asset worth £5,000 has disappeared, so Capital Account is credited with £5,000 and Renewals Fund debited with that amount.

On the purchase of a new locomotive, say, for £6,000 Capital Account is debited with the cost.

As regards the scrap value of the old locomotive, it is considered desirable for the present to credit Renewals Fund with the amount realised (less any cost of breaking up or of sale); this amounts in fact to an additional contribution for depreciation.

In case the locomotive were scrapped at the end of 10 years (*i. e.* 10 years before its estimated life expired) working expenditure would still be charged with depreciation on the engine for the remaining 10 years. If, on the other hand, it lasted 50 years (*i. e.* 30 years beyond its assumed life), no depreciation would be charged on it during the last 30 years.

All assets of the railway (and of subsidiary departments) which are liable to depreciation are treated in the same way, the percentage set aside for depreciation being based on the estimated life. All money for replacements is provided by transfers from the different " Renewals Funds."

[It will be apparent that uniformity with regard to the matter of depreciation must be attained before effective comparisons can be made between two or more railway systems. At present, some administrations rely upon replacing out of current working expenditure capital assets which are no longer serviceable, and as a rule, no distinction is made in their accounts between ordinary working expenditure and expenditure for such replacements. In addition to rendering impossible any comparisons with working results of other railways which meet such special expenditure from renewals funds, such a practice seriously disturbs comparisons on the same railway between the working expenditure of a year when little renewal work has been undertaken, and a year when much of it has had to be done. This it is contended is fair neither to the administration nor to the investor who has provided the capital required for railway purposes.]

Capital expenditure and expenditure for betterment

c) Expenditure for the acquisition of entirely new assets is on the Central South African Railways charged to capital account, and also expenditure for improvements or additions tending to increase earnings or reduce working expenses. Separate records are kept of the capital expenditure of

a) The railway proper.

b) Real Estate Department (dwelling-houses, etc.)
c) Workshops' machinery and equipment.
d) Cartage Department. } (These Departments have separate Capital
e) Catering Department. } Accounts of their own.)

(In the case of the last four items all expenditure for improvements or additions is charged to capital account except in cases where the amount is trivial when it is charged to working expenses.)

In the case of the railway proper, expenditure for improvements and additions is charged to :

Working expenses...	If the amount does not exceed £50.
Betterment Fund ...	If the improvement does not mean the acquisition of entirely new assets or increase earnings or reduce working expenses.

[The importance of securing uniformity in regard to the treatment of expenditure on improvements is so inseparably bound up with the question under consideration that this paper would not be complete were attention not drawn to the fact that there is at present considerable diversity of practice amongst British Colonial railways in regard to the matter.]

PART 4.

Conclusions of Reporter.

Principles of Statistics of Railways in operation.

The majority of the statistics usually prepared on British Colonial railways fall under one of two classes :

1° Those statements or returns (including approximate returns) which are available at a sufficiently early date to serve as an effective aid to operating officers and to the supreme executive head of an administration.

2° Those more permanent records which usually require longer time for preparation and are sometimes of less value for the direction of current operative details than for the purpose of bringing under scrutiny the general results attained as well as the tendencies and influences which the figures indicate so as to serve as a guide to the administration in matters of general policy and finance.

The real test of the worth of statistics of either class in their utility. Money spent in the preparation of statistics which have no value for operating purposes or for purposes of guidance in matters of policy, is money wasted.

In the case of the British Colonial railways, the statistical data taken out varies (as is natural) with local conditions and requirements, and the principle of utility seems to be everywhere well recognised.

In the opinion of the Reporter, the statistical data of a more permanent nature would have much greater value if uniformity were secured in the railway methods of accounting and if an agreement were come to by all railways — parties to this Congress — with regard to such matters at the method of calculating open mileage, train mileage, vehicle mileage, ton mileage, and other units used in the preparation of statistics.

The standardising at any rate of the principal statistical returns and the establishment of a recognised standard classification of statistical data, on lines approved by this Conference, which would be suitable for general adoption, would also add considerably to the value of the statistics of individual railways, since it would enable any one administration to compare results with any other to the advantage of all concerned.

Uniform Classification of Railway Working Expenses.

There is no uniformity in the classification of working expenditure of railways in the British Colonies, although there is a classification common to all the railways in British India.

Generally the classification of such expenditure follows the English model, with such additions and modifications as appear necessary to meet local conditions, but the differences in accounting methods and in the heads of the classification are together so pronounced as to render comparisons between one railway and another either misleading or impossible.

The acceptance of some standard classification of railway working expenditure and of an agreement as to the treatment of expenditure for

a) replacements of capital assets,
b) improvements of capital assets,
c) capital purposes,
d) subsidiary services in connection with railways (such as catering),

would be of inestimable advantage not only to railways in British Colonies but to railways throughout the world generally.

PART 5.

Annexures.

Principles of Statistics of Railways in operation.

1° Draft Forms of Capital Account and Balance-Sheet.
2° Draft forms of Revenue, Net Revenue, and Appropriation Accounts.
3° Specimens of Statistical Forms prepared by British Colonial Railways.
4° Replies of different Railways to questions as to the Statistics found most useful for Operating purposes.

Uniform Classification of Railway Expenses.

5° Draft scheme form Uniform Classification of Working Expenses.
6° Replies of different Railways to questions as to the method of providing, in their Accounts, for depreciation of Capital Assets.
7° Replies to questions as to the treatment of expenditure on Improvements (Betterment).

Capital Account. — Receipts and Expenditure to 30th June, 1909.

EXPENDITURE.	Year ended 30th June, 1909.	Prior to 30th June, 1908.	Total to 30th June, 1909.

Returns of train and engine mileage under classes; returns of costes at different running sheds, coaling, and pumping stations, and comparison with cost on other South African Railways.	dual stations, statistics of earnings and expenditure under sections monthly.
Natal Government Railways.	The weekly statement of traffic indicates the fluctuations that take place and the detailed monthly analysis of commodities is utilised for the purpose of watching revenue received from each class of traffic.	...	The cost of train and engine mileage.	Ton miles.	Statement of staff, increases in pay and numbers. Classification fo appointments. Monthly figures of results.
Cyprus Government Railway.	The classified statements of passenger traffic in money and numbers presented to me monthly and the weekly traffic report, supplemented by verbal advices from traffic inspector, and personal observation.	...	Comparison with corresponding periods and challenging of increases or decreases.	Comparison with corresponding periods and challenging of increases or decreases.	The monthly comparisons of expenditure are the effective checks.
Ceylon Government Railway.	The greatest importance is attached to the goods and coaching comparative return in watching the increase of traffic; these statements are received monthly and show the increases and decreases as compared with the corresponding month in the previous year.	Monthly expenditure is watched and an annual check is kept on expenditure under the various heads per mile of railway open, per train mile, and per 1,000 gros ton miles, and the informations is published in the Administration Report of the Ceylon Government Railway.	The system adopted by us of checking the expenditure on account of locomotives is by engine mileage and carriage and wagon expenditure by vehicle mileage.	...	Taking the expenditure generally, I consider the cost per 1,000 gross ton miles, the freight loads per goods vehicle, and cost of hauling per goods vehicle mile, the number of passengers per passenger carriage, and the cost of hauling per coaching vehicle mile are the best checks on the economical working of the traffic.

Replies of Different Railways to question as to which Statistics are considered most valuable for : 1° Watching earnings; 2° Watching expenditure *(continued)*.

RAILWAY.	1° Earnings.	2° Expenditure.			
		Maintenance of Way and Works.	Maintenance of Equipment.	Running Expenses, Locomotive Department.	Traffic Expenses.
Federated Malay States Railways.	To all statistics.	...	I consider that the check afforded by the total expenditure against each class of stock, divided by the number of such stock passed through the shop and worked out and compared year by year per train mile is an effective check where a large clerical staff is not available.	A statement for the year is prepared, showing cost of department per engine and train mile, against "fuel", "running stores", and wages and material. I consider that these checks are sufficiently effective.	...
Cape Government Railways.	Monthly results of working classified and placed in comparative order, so that rise and fall in any particular items of revenue or expenditure may be seen. These, in conjunction with special returns showing the traffic passing the main junction and depot stations, and the prompt rendering of statements showing the approximate tonnage daily and monthly from the ports to specified sections of line show what is being done on the railways.	Open mile basis is adopted and officers responsible are furnished with details each month.	The costs are compiled monthly by the locomotive superintendent, of the respective systems and checked by the chief locomotive superintendent, who directs attention to any special increase in the rates.	District costs are worked out in the office of the locomotive superintendent, who supplies copies to the district officers and directs attention to any special rate of expenditure.	...
New South Wales Government Railway.	The principal revenue is derived from goods traffic, and all statistics, relating thereto are regarded as the most important. Weekly and monthly statements of the revenue earnings under the four headings are prepared, and constant attention and consideration is given as to how the earnings from each branch may best be increased.	A comparative check of the expenditure incurred under the various schedules in each section, and closely following up all excesses.	Personal supervision and close inquiry into all comparative increases exhibited on the returns produced.	Monthly comparative statements showing each class of expenditure investigated by the head of the branch and criticised and held in check by the administrative committees.	A monthly abstract of the expenditure is prepared under the various schedules.

Annexure No. 5 (continued).

Classification of Indirect (suspense) Expenditure.

In the above classification of working expenditure, it has been assumed that separate records are kept of expenditure on such services as the following, and charged out on some well considered basis to the different departments or accounts which have benefited by such indirect expenditure :

Stores expenses ;
Electric light and power ;
Workshops expenses ;
Labour recruiting charges ;
Sick fund and superannuation fund contributions ;
Insurance premiums and expenses.

Although uniformity in the expense classifications of these separate accounts is not essential at the present time, some particulars are given below (based on the practice of the Central South African railways) both as to the heads of expenditure and the basis of distribution, as the adoption of different methods by different administrations affects to some extent the cost of the other services shown in the preceding classification of working expenditure proper.

Stores Expenses.

Heads of Expenditure.	Basis of Distribution.
Superintendence : Salaries and wages Office and travelling expenses *Other expenditure :* Salaries and wages Offices Travelling allowances Sanitary charges Maintenance of stores buildings Miscellaneous expenditure	A percentage is added to the value of stores issued to cover the stores department expenditure.

Electric Light and Power.

Heads of Expenditure.	Basis of Distribution.
Superintendence : Salaries and wages Office and travelling expenses Wages, other than superintendence Materials Maintenance of buildings Miscellaneous expenses Purchase of power and light Depreciation of plant	Charged out to all departments using electric power and light according to consumption. (Cost of train and station lighting charged to traffic department.)

Annexure No. 5 (continued).

Classification of Indirect (suspense) Expenditure (continued).

Workshops Expenses. — Locomotive Department.

Heads of Expenditure.	Basis of Distribution.
Direct expenses . . { Wages. Material	The expenditure of the locomotive workshops is of two classes: 1. Wages of men actually employed on specific jobs and material used for such jobs (direct expenditure). 2. General expenses which cannot be assigned to particular jobs, such as general superintendence, consumable stores, workshops' stores expenses, power, light, etc. (indirect expenditure). These two classes are dealt with in the following manner: *Direct expenditure* is charged out to the actual work. *Indirect expenditure:* A separate record is kept for each shop of all indirect expenditure, except item *d*), and it is charged out by a percentage addition to the labour charges of any work passing through that particular shop. *Item d*): Use of machinery represents the expenditure for maintaining the machinery and for motive power for driving it, also charges for depreciation.
Indirect expenses . { *Workshops expenses:* *a*) Superintendence . . . *b*) Wages . . . *c*) Material . . . *d*) Use of machinery . . . *e*) Other expenses . . .	

Coloured Labour (recruiting and other charges).

Heads of Expenditure.	Basis of Distribution.
Superintendence: Salaries and wages Office and travelling expenses	
Recruiting expenses: Recruiting fees Clothing, etc., for recruits (value recovered from wages) Railway fares	*Recruiting expenses* charged out to all departments in proportion to number of natives supplied.
Compound expenses Salaries and wages. Provisions Medical attendance Heating, lighting and maintenance of buildings, etc.	*Compound expenses* charged to departments in proportion to number of natives maintained in compounds.
Miscellaneous expenses	*Superintendence and miscellaneous expenses* charged out to departments as a percentage on recruiting and compound expenses.

Annexure No. 5 (continued).

Classification of Indirect (suspense) Expenditure (continued).

Sick and Superannuation Funds (contributions to).

Heads of Expenditure.	Basis of Distribution.
1. Contributions by administration to sick fund	1, 2 and 3. Charged out to departments in which employees are serving. 4. Charged to coloured labour account (see above).
2. Contributions by administration to pension fund	
3. Contributions by administration to sick fund to cover medical examination of applicants for employment . .	
4. Contributions by administration to sick fund for medical attendance on coloured labourers.	

Insurance.

Heads of Expenditure.	Basis of Distribution.
1. *Fire insurance:* Premiums paid to companies . . . . . . — — to administration's fire fund . . . . Fire brigade pay and expenses.	1. Charged out to departments for which insurance is effected, but insurance of all buildings occupied by traffic department or in connection with running of trains is borne by maintenance department; insurance of cartage, catering quarters, and other *buildings* for which rent is charged is a debit to real estate account. Insurance of loco. workshops is a charge to workshops account, and of stores buildings to stores expenses. Insurance of contents in all cases is debited to the department in whose charge such contents are.
2. *Marine insurance:* Premiums paid to companies . . . . . . — — to administration's fund	2. Charged to stores department and added to cost price of stores.
3. *Workmen's compensation insurance:* Premiums paid to administration's fund.	3. Charged to departments employing the workmen as a percentage on the wages paid.

Annexure No. 6.

Depreciation of Capital Assets. — Replies of various Railway Administrations as to the method of providing for Depreciation and Renewals of Capital Assets.

ADMINISTRATION.	Question. Is any provision made in working expenses for depreciation of permanent way, rolling stock, and other assets to provide a fund for replacement on expiration of life? If not, how is such expenditure met as that on the relaying of a whole section or renewing a bridge with the same weight of material, or replacing locomotives, coaches, wagons, or machinery when life is exhausted?	Question. If no provision for depreciation is made at present, are you in favour of charging each year with something on account of that wear and tear which cannot be made good by ordinary maintenance, and do you consider in fixing such depreciation charges, obsolescence should be taken into account? If each year's working is not charged with some contribution for depreciation, and expenditure for replacements is charged to working expenses, do you find that it has a disturbing effect on expenditure and renders comparisons with other years of less value? Also what security have you that economies are not effected at the expense of capital assets?	Question. If provision is made for depreciation, please say how it is calculated. If on the estimated life of the assets, please give the yearly percentage of the cost which is set aside for each class of asset, and say whether labour charges are included in the cost on which depreciation is calculated. Also say how the value of any scrap is treated on replacement. Full information as to the working of the depreciation fund will be particularly valuable.
	Replies.	**Replies.**	**Replies.**
East India Railway .	No. Charged to revenue working expenses.	This is not permissible under Government orders. Our earnings and expenditure are so large that we have found no undue disturbance in our net revenue.	Not made.
Eastern Bengal State Railway.	No. All renewals form a charge to revenue, as capital cannot be charged twice over. Renewals involving improvements are debited partly to capital, the charge to capital representing the value of the improvement.	...	Value of old material is credited to revenue on the renewal estimate.
South Indian Railway.	No. Cost of renewals are generally debited to revenue working expenses.	No. The system of working on this railway does not require the proposal suggested here, as we work on a fixed programme of renewals. Comparison is made, excluding such extraordinary renewals. Budget grant for the year and provision in the sanctioned estimates are the securities.	Value of scrap is credited to the work concerned by debit to stores at the present value. There is no depreciation fund, nor is it necessary.
Assam Bengal Railway.	No.	...	

Annexure No. 6 (continued).

Depreciation of Capital Assets. — Replies of various Railway Administrations as to the method of providing for Depreciation and Renewals of Capital Assets.

ADMINISTRATION.	Question. Is any provision made in working expenses for depreciation of permanent way, rolling stock, and other assets to provide a fund for replacement on expiration of life? If not, how is such expenditure met as that on the relaying of a whole section or renewing a bridge with the same weight of material, or replacing locomotives, coaches, wagons, or machinery when life is exhausted?	Question. If no provision for depreciation is made at present, are you in favour of charging each year with something on account of that wear and tear which cannot be made good by ordinary maintenance, and do you consider in fixing such depreciation charges, obsolescence should be taken into account? If each year's working is not charged with some contribution for depreciation, and expenditure for replacements is charged to working expenses, do you find that it has a disturbing effect on expenditure and renders comparisons with other years of less value? Also what security have you that economies are not effected at the expense of capital assets?	Question. If provision is made for depreciation, please say how i is calculated. If on the estimated life of the assets, pleas give the yearly percentage o the cost which is set aside fo each class of asset, and say whether labour charges ar included in the cost on which depreciation is calculated. Also say how the value of any scrap is treated on replacement. Full information as to the working of the depreciation fund will be particularly valuable.
	Replies.	**Replies.**	**Replies.**
Ceylon Government Railway.	No provision is made against depreciation; expenditure for relaying permanent way and renewing bridges with same weight of material or replacing engines on stock is met from revenue.	I am not in favour of a depreciation account, but would favour annual contributions of fixed sums to a "relaying provision account," "bridges provision account," etc., where the actual yearly expenditure on account maintenance cannot be equally distributed for reasons that are obvious. The charging of expenditure for heavy replacements to working expenses has a disturbing effect on expenditure, but does not render comparisons with other years of less value, as such expenditure is taken into consideration when making comparisons.	Proceeds of sale of scrap are credited to revenue.
Cape Government Railways.	All replacements are performed at cost of revenue.	(*a*) No; except in case of rolling stock. (*b*) No; after a system of railways has been working for a number of years, a normal condition is reached, when the renewals can be regulated on a fairly constant basis, except in the case of rolling stock, in respect of which a depreciation fund should be established. No work is allowed to be undertaken to debit of capital without the express written sanction of the general manager to the department concerned and the chief accountant.	Scrap, except rolling stock, is credited to the working department concerned, and rolling stock is credited to rolling stock account replacement.

Annexure No. 6 (continued).

Depreciation of Capital Assets. — Replies of various Railway Administrations as to the method of providing for Depreciation and Renewals of Capital Assets.

ADMINISTRATION.	Question. Is any provision made in working expenses for depreciation of permanent way, rolling stock, and other assets to provide a fund for replacement on expiration of life? If not, how is such expenditure met as that on the relaying of a whole section or renewing a bridge with the same weight of material, or replacing locomotives, coaches, wagons, or machinery when life is exhausted?	Question. If no provision for depreciation is made at present, are you in favour of charging each year with something on account of that wear and tear which cannot be made good by ordinary maintenance, and do you consider in fixing such depreciation charges, obsolescence should be taken into account? If each year's working is not charged with some contribution for depreciation, and expenditure for replacements is charged to working expenses, do you find that it has a disturbing effect on expenditure and renders comparisons with other years of less value? Also what security have you that economies are not effected at the expense of capital assets?	Question. If provision is made for depreciation, please say how it is calculated. If on the estimated life of the assets, please give the yearly percentage of the cost which is set aside for each class of asset, and say whether labour charges are included in the cost on which depreciation is calculated. Also say how the value of any scrap is treated on replacement. Full information as to the working of the depreciation fund will be particularly valuable.
	Replies.	**Replies.**	**Replies.**
Central South African Railway.	Yes.	...	On the estimated life of the asset concerned : Per cent. Permanent way, etc. . . . 3 1/8 Brick and stone buildings. 1 1/2 Wood and iron buildings. 5 Rolling stock. . . . . 5 Labour charges are included, except in the case of permanent way. Scrap, less cost of demolition, is credited to renewals, as a set-off to the amount transferred to capital account to write out the value of the asset scrapped.
Natal Government Railways.	No fund is created for depreciation, but provision is made in working expenses for the upkeep of permanent way, rolling stock, and other assets. On the other hand, a sinking fund has been introduced, into which large sums are paid yearly with the object of liquidating the capital borrowed in a fixed period of years.	...	...
Cyprus Government Railway.	No depreciation is charged, but the costs of such extra expense will fall in the year that the renewals are required to be paid for from revenue.	Renewals funds are common practice. Certainly. This contingency is so obviously true that it needs no buttressing. No security whatever.	Provision not made.

Annexure No. 6 (continued).

	Replies	**Replies.**	**Replies.**
New South Wales Government Railway.	No special fund is set apart for depreciation purposes, but what is practically equal to a depreciation account is that a certain amount of relaying and renewing of the permanent way and renewing of rolling stock and other works is provided and charged against working expenses each year.	Yes; to a certain extent. For instance, we provide for the wear, and tear that is going on year by year by charging to working expenses all capital works where the estimated cost is less than £100, and by renewing each year out of working expenses what is considered a fair thing. In the case of betterments or improvements the whole charge is debited to working expenses, and in this way it is considered we provide what to a large extent meets the ordinary wear and tear that is going on, and the value of the asset is maintained.	
Trinidad Government Railways.	No. In the one or two cases which have occurred of renewals the charge has been made against net revenue.	*a*) No provision is made at present. We consider there should be a renewal fund, fed from net revenue, as circumstances permit, after payment of fixed charges, which should be available to meet charge for any renewals which cannot be made good in the ordinary course of maintenance. Obsolescence should be included, and credit charges by sales, etc., placed to credit of renewals fund. *b*) Yes; very much so. Destroys comparisons for all useful purposes. Restrictions only on the employment of capital.	None.

Expenditure for Improvements. — Replies of various Railway Administrat

	Question.	Question.	Question.	Question.
ADMINISTRATION.	How is expenditure for improvements and replacements with heavier or better material treated in your accounts, such for instance as : 1° Replacement of bridges by stronger bridges. 2° Replacement of culverts by larger or stronger culverts. 3° Replacement of turntables by larger turntables. 4° Replacement of rails and other permanent way by heavier type. 5° Replacement of buildings by better structures. 6° Replacement of locomotives by heavier engines.	How is expenditure for rearrangement of lines or yards treated in your accounts *a*) where the mileage of track remains the same; *b*) were the mileage of track is increased?	Have you a separate allotment from railway profits for « betterment expenditure » — that is, expenditure for improvements the cost of which is not to be capitalised? If so, please say what classes of expenditure are charged to betterment and what classes are charged to capital account.	Is your system accounting such to make it impo ble to charge capi expenditure to w king, and vice vers
	Replies.	**Replies.**	**Replies.**	**Replies.**
East India Railway.	1°) 2°) 3°) and 5°) The general rule is that so far as the original structure is simply renewed without additions to its extent or to its strength (as in case of girders) or its efficiency or complexity (as in case of signals interlocking, etc.), the charge shall be borne by revenue, and the cost of any additions charged to capital. As regards bridges, capital is debited on basis of increased weight of girders or difference between cost of new girders and original cost of old girders replaced, whichever is less, revenue being debited with the balance of expenditure and credit with value of materials recovered. 4°) Rails : renewals should be sanctioned on a yearly or half-yearly mileage rate, which should include provision for ordinary maintenance. Increased weight in renewal would require special sanction. No charge to be made against capital unless the actual cost of the new rails is in excess of the original cost of those replaced and the new rail is also heavier than the old one, nor shall such charge bear a greater proportion to the cost of the rail replaced than that which the weight of the new rail bears to the weight of the old one. All charges for renewal of ordinary fastenings and chains to be made against revenue. Sleepers : additions to the number originally charged to capital to be charged to capital. The substitution of iron for wood not to be made unless specially authorised, the relative economy of wood and iron sleepers being open to considerable question. It may be agreed that revenue should bear one-third of the increased cost of substituted iron sleepers, and capital two-thirds. Ballast : all additions to the quantity of ballast originally charged to capital to be paid for by revenue after three years from the date of opening a new line, unless the contrary is specially sanctioned. 6°) Capital is debited on basis of increased tractive power, subject to the condition that the amount does not exceed the difference between the cost of the new and the original cost of the engine replaced.	*a*) Substantial improvements are debited to capital. *b*) Substantial improvements are debited to capital, including additional mileage of track.	All works costing less than Rs. 2,000 each, with a maximum of Rs. 25,000 in the half-year, which would otherwise be charged to capital are charged to revenue as new minor works. It may also be noted that the purchase price of the railway is being redeemed by annuities on a 50 years' basis, charged to net revenue account before arriving at divisible profits. This arrangement is to all intents and purposes a setting aside of a large share of the profits on a fund for betterment, as at the end of 50 years the original capital will be wiped out at the cost of revenue.	**Replies.**

How is expenditure for rading and re-aligning the purpose of reduc- curves treated in your ounts?	To what account is expenditure for rebal-lasting or strengthening lines by materially in-creasing the quantity of ballast charged in your accounts?	How is the expense of removal of structures from one place to ano-ther charged in your ac-counts?	When a new line is opened is the expenditure for maintenance during the first twelve months (or less) charged to capital account or to working expenses? If the former, please say for what period capital account is charged.	If capital assets are scrapped and not replaced please say what adjust-ments are made in the books of your line. To what head are such reduc-tions in capital assets charged?
Replies.	**Replies.**	**Replies.**	**Replies.**	**Replies.**
o revenue.	We usually charge addi-tional ballast to revenue. A charge to capital would be altogether exceptional.	Charged to revenue, wor-king expenses.	Anything beyond the sanc-tioned specification for con-struction of the line is charged to revenue. The period is not unduly extended, but a good deal depends upon the season when the line is opened.	*a*) Capital is credited with scrap value, less cost of dis-mantling, provided there is no substitution. *b*) No adjustment is made.

Replies.	**Replies.**	**Replies.**	**Replies.**	**Replies.**
To revenue.	To capital up to a certain limit of cost per mile: above that limit to revenue.	To revenue.	...	...
Charged to revenue, working expenses.	Ordinary ballasting of the line is a charge to revenue, working expenses. Any substantial increase in the depth of ballast to what is already laid as required is a charge to capital.	To revenue, working expenses.	The ordinary rule is that all maintenance charges from the date of opening of a line to traffic are a debit to capital for the first twelve months.	If a work be abandoned and not replaced, the original cost remains at debit of capital. Any materials returned to stores will be credited to capital. If a work be abandoned consequent on the construction of another work or in connection with the rearrangement of the existing work, the original cost of the abandoned portion is a debit to revenue, which will receive credit for materials returned to stores.

Central South African Railways.	If a replacement is rendered necessary, on account of the original asset being worn out, the cost of providing a new one is charged to capital account and the original value of the old asset is written out of capital account by a transfert from renewals fund. If a heavier type of rail is being substituted for a lighter one, the difference in cost between the old and the new (material only) is charged to capital account. The labour in effecting the change is charged to betterment or working. In strengthening bridges the cost is charged to betterment, unless the replacement is governed by the principle mentioned above.	*a*) The cost of moving track from one part of a station yard to another is charged to working. *b*) If additional tracks are provided in connection with the re-arrangement, the cost of the additions is charged to capital.	There is one allotment from net revenue annually for "betterment" purposes. A portion of this allotment is transferred to capital to meet expenditure on new capital works. Expenditure on the acquisition of new assets is charged to capital, and betterment is charged with the cost of effecting improvements to existing works.	It is hardly possi for capital expendit to be charged to wo ing or vice versa, as one instance the au exercised would rev the wrong allocati and in the other capital allocations agreed by the Ch Accountant and Audi before being passed the Railway Board.
Natal Government Railways.	Improved value only debited to capital.	Debited capital if over £100 in value, otherwise charged to betterment.	Yes, for small works under £ 100 in value.	...
Cyprus Governement Railways.	Provision would require to be made in yearly estimates, but the point has not yet risen in this country.	This point has not arisen.	No.	All expenditure capital account is sa tioned by the Secreta of State; the local au tor, having been advi of such sanction, l complete control.

REPORT N° 2

(Great Britain)

By W. M. ACWORTH.

When I am invited to report for the International Railway Congress on the subject of Railway Statistics in the United Kingdom under the two heads of *a)* principles of statistics of railways in operation, and *b)* uniform classification of working expenses, I am reminded of a time-honoured story. An author once wrote a book on the zoology of Ireland. One chapter was headed " Snakes in Ireland ", and the contents of the chapter were the words " There are no snakes in Ireland ". Similarly there are in the United Kingdom no principles of statistics of railways in operation, and there is no uniform classification of working expenses. I might therefore end my paper at this point, for it would be an absolute waste of time to discuss such statistics as at present exist for our English railways, to point out their lack of principle, the want of form and symmetry in such statistics as do exist, and the still more important *lacunæ* which our present statistics, such as they are, leave unfilled. As for uniformity of classification, one instance may suffice. The heading of expenditure entitled " maintenance of way, works and stations " is, in our existing forms, divided into four subheads. The chief engineer of one of our great railways a few years ago described these four sub-heads as four paper baskets, which stood by the side of the table of the engineer of each railway company. It was, he said, a matter of pure accident into which of the four baskets any particular item of expenditure happened to be thrown.

But in order that the Congress may not be without some information as to the

position of British railways from the statistical point of view, it is perhaps worth while to give some account of the history of the subject. More than forty years ago, in the year 1868, an Act of Parliament required all railway companies to prepare and publish, half year by half year, a report with accounts and statistics according to forms laid down in detail by the Act itself. The forms prescribed by the Act of Parliament could only be altered by the Board of Trade with the consent of the company concerned. Naturally therefore, as a change could not be generally introduced without the consent of every company, the forms prescribed by this Act have remained substantially unchanged from that day to this. Three years later, however, a further Act required the railway companies to furnish annually certain further information to the Board of Trade. By an amending Act passed in the year 1888, the Board of Trade was given power to add to and vary these returns as they from time to time might think expedient. The Board have, however, hitherto made very little use of this power to obtain fuller information. The most important instance, perhaps, occurred in the year 1903, when for the first time they called for statistics as to the length of siding mileage, which, up to that date, no company published, and which some at least of the more important companies did not actually possess, even for their own information.

For many years there have been complaints both of the inadequacy and of the inaccuracy of the information furnished. Complaints of the former nature have mainly been made by outsiders, for the idea that a railway is a private undertaking, like a grocer's or a butcher's shop, and that the public have no right to the information is deeply ingrained in the English railway mind. But the railway men themselves have frequently complained on the ground of the inaccuracy. The schedules of the old forms of forty years ago are of course quite incapable of finding room for all the complexities of modern railway business, and in the absence of any controlling authority to decide to which of the existing schedules a given expenditure can best be allocated, no one heading means the same to all the companies, and all comparisons between one company and another of expenditure for what are nominally identical objects, are vitiated in consequence.

One or two instances may be given of the impossibility of putting the new wine into the old bottles. Within the last thirty or forty years, our railway companies have embarked very large amounts of money in hotels and in steamboats, and the practice of one company running over the line of another company has very greatly increased. The capital expended on hotels, and it must amount to many millions sterling, has hitherto been returned as " expenditure on lines open to traffic ". But the revenue receipts and expenditure from these same hotels does not appear under the head of traffic receipts and expenditure, but is entered separately as " miscellaneous ". Again, in the case of steamboat traffic, the receipts in some cases have been entered as railway receipts and have accordingly, when divided by the train mileage run, unduly inflated the receipts per train mile, as compared with those of another company which kept its steamboat receipts and its railway receipts

separate.' Once again, the gross railway receipts of a company have been made up of three items, *a*) receipts earned by its own trains on its own line ; *b*) its portion of the receipts earned byi ts own trains on another company's line ; *c*) its portion of the receipts from trains of other companies run over its line. And this hotch-potch figure has been used as the sum to give, when divided by the gross receipts, the receipts per train mile. These instances, and they are only instances which might be multiplied indefinitely, will perhaps suffice to show how dangerous it has hitherto been to attempt to compare English railways amongst themselves and still more with those of other countries on the basis of the published figures.

In June 1906, the President of the Board of Trade appointed a Committee " to consider and report what changes, if any, are desirable in the form and scope of the accounts and statistical returns (Capital, Traffic, Receipts and Expenditure) rendered by railway companies under the Railway Regulation Act. " That Committee sat for three years, and they made a report recommending an entirely new form of accounts and statistical returns. This form, which is printed in full as an appendix to this paper, was unanimously agreed to by the Committee. Attention may be called to the main reforms therein recommended. It is proposed :

1° That the present duplication of reports issued to shareholders and returns made to the Board of Trade be done away with, as the proposed new forms of accounts and statistics include all the information hitherto furnished to the Board of Trade additional to that given to the railway shareholders ;

2° That the reports be made yearly instead of half-yearly ;

3° That the reports be divided into two parts : *a*) accounts proper, and *b*) statistical returns ;

4° That uniformity in the keeping of the accounts and statistics in future be provided for by the appointment of a standing committee to decide what is the proper heading under which entries should be made, and to see that all the companies make their entries accordingly ;

5° That separate accounts be kept of all the various businesses carried on by railway companies — docks, steamboats, hotels, canals and the like, so that in future it may be possible to disentangle the capital expenditure and also the income receipts and expenditure of the railway proper from the figures of the railway company's undertaking as a whole ;

6° That provision, too elaborate to be more than alluded to here, be made to secure that in future the capital of the company be brought into relation with the property owned, and that the expenditure be brought at least into some relation with the work done and the receipts therefrom ;

7° That statistics be furnished which, if not so full as those given in most other countries, will be at least very much fuller than anything that has hitherto been published in this country.

On looking at the new forms proposed for adoption by the Committee, it will be observed that very little has been done in the direction of making the English classification of working expenses correspond with those of other countries. However desirable such uniformity may be, and the present writer would be one of the last to underrate the desirability, the Committee (and I speak here as a member of it) found it practically impossible to make any steps in this direction. To bring English railway accounts into line with those of other countries would necessarily mean a complete break with the past and an entire change in English methods of railway book-keeping. Such a change could hardly be introduced without the cordial co-operation of the railway companies themselves, and this co-operation the companies, rightly or wrongly, were not prepared to give. It was impossible for the Committee, therefore, to avoid taking existing English accounts as a basis and recommending their improvement along traditional lines. If the Report of the Committee is approved and acted upon by the Government and legislation passed to secure the adoption of the forms recommended by the Committee, we shall get a uniform classification of working expenses throughout the United Kingdom. But it must be left for a new set of men under new conditions to work towards the still more important aim of a uniform classification of working expenses throughout the civilised world.

Dealing with the other head of the subject, namely principles of statistics of railways in operation, attention may first be called to forms Nos. 1 to 7, which are headed Capital Accounts. These accounts are, I believe, fuller than the corresponding accounts of the railways in any other country, and the reason, as usual in England, is a historical one. In no other country, as far as I am aware, where the railways are private enterprises, is the creation and issue of fresh capital subject to the constant and detailed control of Parliament. A British railway company can only issue capital at such times, and in such amounts, and for such purposes, as may be specifically authorised by Parliament in each individual case. The first section of the accounts, therefore, sets out, in full and in great detail, first the authority for each capital issue; secondly, the extent to which that authority has been exercised; and thirdly, the purposes to which that capital, so authorised and issued, has been devoted. For the particular year to which the accounts relate, the details are further elaborated, and the capital accounts conclude with two forms, the first of which (No. 6) gives under appropriate headings an estimate of further expenditure on capital account which the company has in front of it; while form No. 7 shows what unexhausted capital powers the company has available to meet the contemplated expenditure.

The next group of forms (Nos. 8 to 19) are headed "Revenue Accounts". In forms Nos. 8 and 9, the accounts of the undertaking as a whole are dealt with in a summary form. The total receipts of all the various branches of the business, railway, steamboats, canals, docks, etc., are brought together; the total net income is established, and the proposed appropriation thereof to the payment of interest, to

dividend and to reserve funds set out in logical order. Accounts Nos. 10 to 17 form a complete series, giving receipts and expenditure in respect of each separate business of the company. No. 11, for instance, gives receipts and expenditure in respect of omnibuses and other passenger vehicles not running on the railway. No. 13 receipts and expenditure in respect of steamboats, and so on. These accounts, however, which only concern the subsidiary undertakings, have been kept as concise as possible, and need not be further dealt with here. The important account is No. 10, Receipts and Expenditure in respect of Railway Working.

Just as account No. 8 was a summary of the receipts and expenditure of the whole undertaking, No. 10 is really only a summary of the receipts and expenditure of the railway proper. Sub-accounts of expenditure, under the main heads of maintenance of way, maintenance of rolling stock, locomotive expenses, traffic expenses, etc., and to some extent sub-accounts of receipts, are given as supplemental to account No. 10, under the time-honoured English name of " abstracts ". It will be seen by anyone who is acquainted with the form of accounts at present used in England, and who studies the proposed new expenditure forms, that, while they are by no means so full as those in use in some other countries, they constitute a vast improvement on anything hitherto existing in this country. Abstract A, " Maintenance of Way and Works ", for instance, provides for twenty separate entries, where the old accounts provided for only six; and it will for the first time show in reasonable detail where the money spent has actually gone; while, when taken with the corresponding statistical return (No. X) of the work done and the materials used, it will give a fair idea of the value that has been received given in return. Moreover, and this point need not be repeated at every stage, by its provision of this large number of separate headings, coupled with the proposal for a standing committee to rule on questions of interpretation from time to time, it takes reasonable precautions to insure that the accounts of the different companies shall be in future fairly uniform, and comparable under their separate headings, the one with the other.

The two following abstracts, B and C, deal respectively with the maintenance and renewal of rolling stock and with locomotive running expenses. The traditional English organization, by which the same department maintains the locomotives and controls their working out on the road, made it impossible to adopt the logical division, which would naturally be to put all running expenses together. But at least something has been done in this direction. Running expenses of locomotives have for the first time been definitely separated from maintenance expenses; and in the following abstract D, Traffic Expenses, the wages of guards, and the cleansing, lubricating and lighting of vehicles, have for the first time been set out as separate items So that in the future, by adding these items to the locomotive running expenses it will be possible to get some rough idea of the out-of-pocket cost of running a train. Further, it will be noted that rolling stock cost is to be divided under four main heads : additions to stock, replacement of stock,

repairs of stock, and general shop cost. Once more a statistical return, No. XI, gives a record of the work done, corresponding with the payments shown in the accounts as made.

At this point notice may be taken of the fact that, on the expenditure side of the account, no distinction is made between goods and passenger traffic. No doubt any attempt to distinguish between passenger-cost and goods-cost must be more or less inaccurate, and must to a considerable degree rest on estimate and apportionment. In the view of the present writer, however, the division, imperfect though it be, is valuable, and ought to be made. But reports of Committees must always be of the nature of a compromise, and the view of the railway companies, that as a rule information is better withheld than given, coupled with the view of the precise statistician, that estimates should not appear in accounts purporting to record actual arithmetical facts, have in this case not unnaturally prevailed.

One other sub-account, Abstract F, must be noticed on the expenditure side. It is really an expense account, though it appears among the receipts. It is headed " Collection and delivery of parcels and goods and other parcels traffic by passenger train ". It is no doubt generally known that, on English railways, the rates for merchandize traffic normally include, not merely railway carriage, but collection from the consignor and delivery to the consignee, no separate charge being made for these latter services. Hitherto the practice of the companies has been, to set out their gross receipts from goods traffic; then to show the cost of collection and delivery of all traffic, whether by goods train or by passenger train, as a deduction therefrom, and to enter the balance in their accounts as goods traffic receipts. In future, the expenses of collection and delivery will be set out in detail; the amounts charged against passenger-train-traffic and goods-train-traffic respectively will also be stated; and these respective amounts deducted from passenger-train-receipts and goods-train-receipts as the case may be.

The weakest point in the proposed new accounts — accounts proper as distinguished from statistics — is undoubtedly to be found on the receipts side of table No. 10. Objections that were found, or at least believed, to be insuperable were urged against any detailed division of the railway receipts. And in the upshot the Committee have been contented to recommend a very bald list of entries. Passenger receipts are all lumped together under three main heads : Ordinary tickets, first, second and third class, season tickets, first, second and third class; and workmen's tichets. The phrase " ordinary tickets," though sanctioned by long usage, is entirely misleading. It includes not merely single tickets isued at the normal mileage fare and ordinary return tickets, but also hundreds of millions of tickets at rates frequently not exceeding a farthing a mile, excursion tickets, market tickets, special golfers', anglers', bicyclists' tickets, soldiers' and sailors' tickets, week-end tickets, privilege tickets, and other tickets at exceptional fares much too numerous to specify in detail.

In the case of goods traffic the lack of detail is even more painfully apparent.

Merchandize receipts — and they amount on the British railways to £30,000,000 per annum — are given in one lump, no attempt whatever being made even to distinguish between what the Germans call *Stückgut* and large consignments. Livestock; coal, coke and patent fuel; and other minerals : each have a separate line to themselves. And that is all.

The statistical returns (Nos. 13, 14 and 15) relating to the traffic receipts, do not carry matters much further. In the case of passengers, it is proposed to state the number under the same headings of ordinary, season-ticket and workmen, and also — and this is undoubtedly a valuable addition — the number originating on each company's system. Our Board of Trade reports of the number of passengers conveyed on British railways have hitherto been merely a total of the number of passengers conveyed by each several company, and, as in London and other great towns a passenger travelling only three or four miles may quite well use the systems of three separate companies, the number of actual passenger journeys made at ordinary fares is probably one or two hundred millions less than the Board of Trade figures. A similar column, "Tonnage originating on the Company's system" is given, and for the same reason, in the statistical table dealing with goods traffic. Statistical table No. 15, to be filled in by stating separately "the tonnage of the principal articles of traffic originating or terminating on each railway company's system and carried in consignments of not less than two tons," will no doubt be of some use in indicating, at least in outline, the nature of each company's main traffic, and the proportion of the whole which is carried in consignments of less than two tons.

But this brings me to a point on which I would desire, though I cannot entirely ignore it, to say as little as possible. So much of the report of the proposed accounts and statistical returns as have been dealt with hitherto represents the unanimous recommendation of the Committee. But on the question whether figures of ton mileage, passenger vehicle mileage, and wagon mileage, should be compiled and published, the Comittee were sharply divided. It is no doubt commonly known that English railway companies do not, with one conspicuous exception, compile such figures. According to their official statements the compilation of any such figures is useless and unreasonably expensive, and their publication is misleading and in the highest degree objectionable. I shall not of course attempt to discuss the question here. To tell a railway man of any other country, who would as soon think of doing without these figures as a doctor would think of dispensing with a clinical thermometer, that they are valuable, would be merely absurd; while to attempt to argue with the English railway men, who have already made up their minds (though possibly on grounds other than the extremely inadequate reasons which alone they adduce in public), would be equally waste of space. But the history of the matter before the Committee is worth recording. The Committee consisted of nine members. Three of them represented the railway companies; and their atti-

tude I have already indicated. Three members had before their appointment publicly asserted the necessity for these figures. The remaining three members, among whom was the Chairman, approached the subject with no preconceived opinions. After much discussion and hearing a considerable number of witnesses, only one of whom, however, was not an Englishman, the two groups of three on either side remained not unnaturally of the same opinion still, while the centre three came to an intermediate conclusion. They reported in effect that the result of the evidence and discussion was that the statistics in question would be of value; that the cost of compilation would not be great; and they ended in "recommending this class of statistics to the careful consideration of those responsible for railway working in this country, with a view to seeing whether they could be more widely introduced." But they went on to say that "a large part of their usefulness might be lost, if their compilation resulted solely from compulsion," and that "there is not sufficient ground for insisting on their being compiled by all companies, unless and until they come to be adopted by a considerable number of the important companies".

From this conclusion the two groups on either side recorded their dissent. The three railway members put in a reservation claiming that these statistics were useless. The three remaining members put in a reservation to the effect that there was no ground for treating these returns differently from all other returns. If compulsion was to be applied in one case, why not in all? They knew no reason "why a large part of their usefulness might be lost if their compilation resulted from compulsion," and they further expressed the opinion that the information thereby given was information to which Parliament and the public, all well as the shareholders, kad a right to have access. In order to give effect to their opinion, they accordingly recommended the incorporation, along with the forms given in Appendix 1 of their report, of the additional set of forms published in Appendix 2.

It now only remains to be seen what attitude the Board of Trade and Parliament will adopt in reference to the matter.

APPENDICES.

APPENDIX 1.

Form of accounts and statistical returns.

PART I. — FINANCIAL ACCOUNTS.

Year 19 .

(*Nos. 1 to 7, capital accounts.*)

No. 1*a*. — Nominal capital authorised and created by the company.

REPORT N° 3

(all countries except Great Britain, British colonies and America)

By Mr. BARRIOL,
CHIEF OF DIVISION, PARIS-LYONS-MEDITERRANEAN RAILWAY.

SUMMARY.

I. — *Introduction.*
II. — *Principles of statistics of railways in operation.*
A. — General observations.
B. — Statistics of cost of establishment, financial resources, charges.
a) Installation of lines;
b) Rolling-stock;
c) Tools and appliances;
d) Stores;
e) Financial resources;
f) Charges
C. — Statistics of revenue :
a) Revenue in general;
b) Grande vitesse receipts :
Passengers;
Luggage, dogs, etc.;
Grande vitesse goods.
c) Petite vitesse receipts;
d) Miscellaneous receipts;
e) Statistics of revenue per station and line.
D. — Statistics of expenditure.
E. — Various statistics.
F. — General statistics.
III. — *Uniform classification of working expenses.*
A. — General remarks.
B. — Expenses. — Central administration.
C. — Working expenditure properly so called. — Internal and general traffic.
D. — Expenses of locomotives and rolling stock.
E. — Expenses of maintenance of way and works.
F. — Miscellaneous expenses.
IV. — *Conclusions.*

I. — Introduction.

The report upon this question, entrusted originally to the late Mr. Hodeige, inspector-general of the management of the Belgian State Railway, was placed, after the decease of the latter gentleman, in the hands of the Hon. Mr. De Geynst, inspector of management of the same railway. Reasons of health have prevented our colleague from pursuing the work, which has thus devolved upon us under somewhat difficult circumstances, and it is rather as a substitute, than as the responsible reporter, that we have completed the present study.

Mr. Hodeige had drawn up a detailed list of questions with the view of eliciting the information necessary for the adequate treatment of the subject confided to his care. We reproduce this list of questions as an annex, with the explanatory note which accompanied it (appendix 1).

It is divided into four parts :

1° System of classification of working expenses ;
2° Particulars of lines in operation ; length, gradients, curves, stations and yards ;
3° Particulars of rolling-stock ;
4° General results of the working ; revenue, expenditure, traffic, mileage run.

This division does not correspond exactly with the wording of the question as it was framed by the Permanent Commission of the Congress.

It would have been better, perhaps, to have observed the order indicated in that wording, which would have led to the completion of the list of questions by a request for information regarding establishment expenses, the net cost of the lines, the resources which served to effect the construction, details of the traffic, and a complete analysis of the various matters relating to revenue and working expenses. The reporter would thereby have been enabled to formulate interesting comparisons between the various documents communicated by the administrations.

Lacking the necessary elementa, and pressed for time, we have been obliged to confine ourselves, as far as possible, within the general limits laid down by Mr. Hodeige, and to renounce, to our great regret, the idea of giving to the subject all the amplitude it deserved.

The railways which responded to the appeal of Mr. Hodeige number forty-five, and a list of them is given, with a comment upon the replies, in annex II. We can only regret the brevity of certain of the answers, which simply refer to administrative documents not containing the information desired.

However, despite the limited time left at our disposal, it has appeared to us impossible merely to reproduce the replies of the administrations.

We have endeavoured, therefore, dealing with the question as it was put, to

evolve from the documents received the essential bases of the statistics which it would be desirable to see established by all railway administrations, together with a uniform classification of the working expenses, which might have been discussed.

In our opinion, studies of this kind can only bear fruit if they consider details; for the headings of accounts or statistics being necessarily very general, with a view to being short, one finds, sometimes, very diverse elements in accounts of a similar character kept by railway administrations of one and the same country, and, *a fortiori* by administrations of different nationalities.

II. — Principles of statistics of railways in operation.

A. — General observations.

Whatever the organized financial methods of railways may be, and whether the latter belong to private companies or are operated by the State, the principal object of the administration should be the avoidance of a deficit which, in the former case, is prejudicial to the shareholders, and in the latter burdens the tax-payers, some of whom would be injured to the advantage of those who utilized the means of traffic to a preponderating extent.

It is necessary, then, to seek to maintain in equilibrium the receipts and expenses, adding thereto, if required, the charges for interest and amortization and the various company charges.

In order to effect this equilibrium, it is requisite to study the results arrived at during the preceding financial years, that is to say to keep perpetually in view statistics of all the elements of revenue and expenditure. A great number of these elements result from the classification of the various operations of revenue and expenditure by the accountants' department, which enters them directly in special accounts; but, apart from these statistical elements, which are purely matters of book-keeping, it is necessary to establish others by means of returns specially designed to enable forecasts to be made of the future of the undertaking. We shall be careful to mark, as far as possible, the distinction between these two very different categories of statistics, the first of which is almost inevitably rigorous in character, whilst the second, more or less exact, depends entirely upon the executive agents and the supervision exercised over them.

In any scheme of railway statistics it is necessary to admit at once three groups : *Revenue, expenditure*, and *charges*. From the strictly-logical point of view, it is preferable to study, in the first instance, the statistics relating to charges, for these result from resources corresponding to the establishment expenses of the lines, that is to say from the very origin of the railway.

But, independently of these groups of statistics, there exist a great number of auxiliary statistics, relating either to the traffic itself or to exterior matters, which are of not less considerable importance than those indicated, and which facilitate the determination of the coefficients, the ratios, utilized in comparing different railway systems.

To sum up, railway statistics may be grouped as follows :

Statistics of cost of establishment, financial resources, charges;
Statistics of revenue;
Statistics of expenditure;
Miscellaneous statistics.

B. — STATISTICS OF COST OF ESTABLISHMENT, FINANCIAL RESOURCES, CHARGES.

a) *Installation of lines.* — Mr. Hodeige has indicated with perfect accuracy in his list of questions the various statistics requisite to enable a distinction to be drawn between the lines, according to their dates of concession and opening, the time employed in their construction, and their length, a separation naturally being made between single, double and multiple lines, and account being taken of the gauge.

Returns of a very simple character ought to suffice to show the length of the rails according to their composition (steel, iron) and cross-section, as well as the nature of the track, both as regards the sleepers (iron, oak, soft wood, creosoted or otherwise) and the ballast employed, with the quantity of these materials.

The return of the numbers of stations, yards, stopping places, level crossings, overbridges and underbridges, bridges according to their span, their height, etc., gives results which should be completed by a statement of the unit prices.

These it is unfortunately very difficult to find in the majority of cases from the replies addressed to us.

As a matter of fact, the administrations content themselves generally, with dividing up the establishment expenses under certain headings and sections which differ greatly according to the particular administration.

We gladly recommend the following division :

I. — General expenses, including general costs of management, of central administration, etc.
II. — Purchase of lands, expropriations, law expenses, etc.
III. — Earthwork, constructional works.
IV. — Permanent way and ballast (materials).
V. — Station buildings, workshops, stores, depots, telegraphic installations, etc.

These statistics of expenditure are drawn from the accounts, but their value must not be exaggerated, for in attempting to unify the establishment records of two constructive services attached to the same railway, and in going into the details of the items, we have discovered notable differences of interpretation.

Other distinctions can be made, and will give rise to interesting statistics and comparisons, if, the systems being the result of concessions, the State becomes a party to the expenditure, whether by guaranteeing a certain proportion of the latter, by granting subsidies, or by having the various construction works executed by its engineers or by those of the Companies.

We must distinguish, equally, the buying-up of lines, transfers, amalgamations, etc.

b) *Rolling-stock.* — Statistics as to rolling-stock relate to the nature and cost of the vehicles.

Locomotives will be included in accordance with their type, power, number of driving and carrying axles, and their use on the road; they will be distinguished according to whether they are coupled or not to the tenders, etc., and, finally, their unit price will be determined and their cost per kilogram of material.

Passenger carriages will be divided up into types or classes, in accordance with the number of seats available, the number of carrying axles, the bogies, the kind of lighting and heating, and the unit price. Similarly, the goods wagons, the vans, will be classified as covered or open : special trucks for heavy materials, etc., care being taken to note the ordinary load, and the unit price.

c) *Tools and appliances.* — The tools and appliances alike of the constructive services and the workshops and depots are made the object of detailed inventories, as in the case of rolling-stock. The statistics are therefore very easy to keep, and the quantities and unit prices will be easily determined.

d) *Stores.* — We will add to the cost of establishment the stores, although nearly one-third, at least, of the value of the materials supplied might be considered as probable working expenditure.

They are the object of detailed inventories which permit of the classification of the plant, fuel, road material, rails, sleepers, etc., according to their kind and price. Unfortunately the detailed statistics are rarely published, and it is rather difficult to discover points of comparison between the systems.

e) *Financial resources.* — The financial statistics are very simple. It suffices to distinguish the origin of the resources and the nature of the loans, in any.

The classification of subsidies of the State, of communes, and of private persons, paid in capital, in kind, in short or long annuities, and of the resources derived from subscriptions in shares or bonds, will effect itself, thanks to the ordinary process of bookkeeping.

But it will be necessary to keep special statistics in order to ascertain the cost of the printing of the share certificates, the expenses of issue brokerage, cost of negociation, service expenses, etc., and although accounts may be of great assistance in these

determinations, there cannot fail to be a good deal of arbitrariness in the estimate of such special expenses, often difficult to localize.

Statistics of this kind make it possible to follow the variations in the rate of issue, and to appreciate by comparison the credit enjoyed by the respective railway systems; but the calculations necessary to this end are much less simple than is usually believed.

Let us call to mind the statistics relative to the circulation of the securities, whether to bearer, or inscribed; to their distribution among the public, to the importance of the small notes or coupons, etc.

f) *Charges.* — Charges may be divided up into interest, redemptions and accessory expenses. The rate of issue of the securities, their nominal capital value, their period of redemption, and the method of such redemption (annuities fixed, variable) determine the proportions of the three special species of charges, and render it easy to establish statistics which are purely matters of accounts and therefore rigorously exact.

The attribution of these charges in levies upon the proceeds of the working may form the object of statistics of a wholly special character, notably in France, but in view of their character it is not convenient to insist upon these.

C. — Statistics of revenue.

a) *Revenue in general.* — The revenue develops in two ways (assuming properly-established tariffs), either by an augmentation of traffic upon the lines already existing, or by an increase in the length of the system. Statistics reveal the first mode of variation, and facilitate the establishment of the probable result of the second.

The traffic being made up of very varied elements, the statistics relating to the elements of revenue are very complex.

In general, distinction is drawn between two great categories of revenue in the shape of *grande vitesse* (passenger and parcels) and *petite vitesse* (goods) traffic; but some systems add to these a third category of accessory receipts which are not traffic receipts properly so called (1).

This classification, created somewhat artifically at the period of the origin of railways, is rational enough; it divides the traffic receipts into two parts which, if not equal, are at any rate, sufficiently nearly so.

In general, it will be necessary to make daily returns of revenue received in order to establish comparisons with the preceding financial years. There is scarcely need to say that such comparisons will only be of utility as regards anticipations of the

(1) Certain systems adopt a classification of revenue according to the nature of the traffic : passengers, goods, various.

future if account is taken of variations due to holidays, to the 29th day of February, to political events, etc., but this process as regards any general collection of statistics of the kind is evidently indispensable, and is the first point which occurs to one's mind.

It is necessary, finally, to mention the differences which exist between the methods of bookkeeping of the various railway administrations, some of which make a return of receipts actually cashed, and others of receipts for which a written order has been given, but the cashing of which will be effected later on. The latter mode of procedure should be the rule for Companies with a limited concession.

b) " *Grande vitesse* " *receipts.* — *Grande vitesse* receipts are divided into varying categories, according to the system and the country : passengers, luggage, dogs, cash, postal packets, horses, cattle, warehousing, parcels.

All the receipts, authenticated by actual cash collections, are easily localized, but it is necessary to discriminate between them further with a view to obtaining information as to price, kind, weight, and if possible bulk.

Passengers.

Passengers will be distinguished by class and by character of trains, if there is an extra charge for express trains. Enumeration will be made of the number of tickets issued by the stations for this or that destination; of passenger-tickets at full fares, at $^1/_2$, $^1/_4$ at $^1/_{10}$ fares; return-tickets; season tickets; tickets for routes according to section, district, canton, department, system, country; tickets for excursions, society gatherings, pilgraimages, congresses, etc.; combined circular tickets, emigrant tickets, military traffic, penitentiary traffic, etc.

The effective recording of these elements will enable one ultimately to forecast, almost exactly, the probable revenue under given circumstances, to determine approximately the probable passenger receipts of a new line, etc.

The passenger statistics will be of service in ascertaining the alterations of class, the mean distance travelled, the reason of these variations and the effects upon the ultimate proceeds of the working.

The checking-off, approximate otherwise, of the total mileages of passengers, assists in the determination of the average fares and of the average mileage, which afford an approximate estimate of the yield of a new line, or of a shortened route. It would not, of course, be advisable to apply the figures thus obtained to anticipations with regard to new countries.

Let us confine ourselves to recording the fact that some railway systems record the averages of passengers per track-kilometre, per locomotive-kilometre, per train-kilometre, or even per axle-kilometre.

Luggage, dogs, etc.

As regards luggage, dogs, the transport of cash, details of weight, bulk and value might usefully be recorded.

The conveyance of postal packets and parcels should be the object of detailed statistics, with the view of developing a very special class of traffic between one country and another, or even between two points of the same country, notably the traffic in early produce, fruits, flowers, etc.

Finally, as regards the conveyance of carriages, horses, cattle, statistics will show clearly the conditions of development of certain industries (carriage-building, motor cars, etc.) and of the breeding of stock; it will raise questions of amelioration of tariff, or methods and conditions of transport.

" Grande vitesse " goods.

Grande vitesse goods belong to very special categories, being either perishables, or fancy goods the cost of conveyance of which is only a negligeable addition to the price of the material: it is obviously necessary to establish distinctions between each class of goods in order to be able to either modify the tariffs, or ameliorate the conditions of transport as regards wagon accommodation (refrigerator van, baskets, packing, etc.).

c) " *Petite vitesse* " *receipts.* — The *petite vitesse* groups include, for the most part, goods and animal traffic, but not in so great a quantity as in the case of the *grande vitesse.*

The differentiation of goods can be carried out to the fullest extent. It is impossible to be too exacting on this subject, and statistics will render great service in the establishment of tariffs applicable to new materials which industry may have created, or which, extracted from the earth, may have come into common use. Such new materials can be classified by analogy as regards utility, employment, etc.

But the interest in this information would be even greater at the period of the establishment of a new line, or when shortening a line already established, in that they would enable a forecast to be made of the development of the traffic, or the effect of the partial withdrawal, which might have very serious consequences for private companies, bound to the State by special conventions.

As in the case of passengers, an approximate return ought to be made of the mileage of each ton carried.

The problem is complex, for the bulk of the various goods differs in very considerable proportions.

By comparing the number of ton-kilometres of the goods (that is to say Σtp, t representing the weight of the goods and p the distance they are carried, with the number of train-kilometres or the number of carriage-kilometres, one obtains sta-

tistical ratios all the more interesting because the systematic errors which result from the establishment of numerical data remain practically constant, so that the coefficients remain comparable as between one year and another. Such are : the average load of a goods train and of a goods wagon; these are characteristic of the good or bad utilization of the stock and consequently of the good or bad working.

In the case of goods, statistics should be kept of the usage of the wagons according to their kind, with a view to a proper account being rendered of the utilization of stock. Furthermore, such statistics furnish a very important index to the value of the probable revenue in taking account of the wagons standing still, or circulating outside the system. This estimate, quite approximate of course, facilitates the verification of the indications of revenue resulting from the paying-in of the stations.

Finally, the analysis of goods traffic by tariffs, according to whether they are normal, exceptional, combined, whether they belong to unions, or to special tariffs from country to country, gives rise to statistical enumerations of considerable importance, although few systems have been willing to go to the expense necessary to carry out this rather delicate task properly.

Certain companies charge to the *petite vitesse* receipts the service traffic, that is to say, the traffic which they effect on their own account or on that of the State, if they provide for it. In general, the traffic carried in this way is rated at very low contract rates, which falsify to a certain extent the working receipts. It is hardly necessary to exaggerate the error which is thus committed, for the service freights represent scarcely 2·5 per cent of the amount of the total receipts, and the lessening of revenue is certainly under 0·4 per cent of this total. It has for counterpart a diminution of the establishment or working expenses.

Let us simply remark that the charging to revenue of the service freights, a system of which we are personally a convinced partisan, has the effect of somewhat augmenting the working coefficient which would have been obtained if one had placed them to the credit of expenditure.

d) *Miscellaneous receipts.* — This group of receipts does not exist in the case of all the companies. It nevertheless appears rational enough, for it permits of a clear distinction being drawn between the traffic receipts, and the non-traffic receipts inherent in the very existence of the railway : proceeds of estates, lands not utilized, stations held in common with other companies, letting of stock, investments, etc.

These accessory receipts are otherwise of little importance, and represent in the case of the various companies only 1 to 2 per cent, at most, of the total revenue.

They should be detailed with care, for in general their collection gives rise to complicated operations; let us mention, for example, the proceeds of investments, which lead to the very interesting treasury and currency movements.

e) *Statistics of revenue per station and line.* — Statistics of revenue according to station are a purely treasury matter, but that which is specially important to

indicate is the distribution of the receipts according to line, each of these being assigned the share reverting to it from the cash receipts effected either through the stations or agencies of the system, or the stations or agencies outside.

These statistics have already been made the object of special study. They could not be dealt with again without our running the risk of repetition; nevertheless, this further reference to them was necessary, for in certain countries (France in particular) their importance is considerable in connexion with special conventions based upon the gross kilometric proceeds of the lines.

Let it suffice to recall the fact that the processes of apportionment or localization of revenue are approximate, and that their results, although nearly allied to the facts, cannot be expected to be absolutely exact.

D. — Statistics of expenditure.

The whole of the railway companies or administrations have adopted in principle a similar classification of expenditure, divided under four or five principal heads, *viz.* :

Central administration.
Working properly so-called, internal and general traffic.
Locomotive and rolling stock.
Maintenance of way and works.
Miscellaneous.

But we have only had to compare with each other the documents addressed to Mr. Hodeige in order to discover important differences in detail.

Thus, the cost of the checking and supervision of revenue are classed, sometimes among the general expenses, sometimes among those relating to traffic; pensions and retiring allowances are sometimes incorporated with the general expenses, sometimes charged in the augmentation of the staff expenditure of each section, sometimes, finally, placed among the miscellaneous expenses. The same thing occurs with regard to taxes, expenses of control, compensation and legal costs, which are placed either among the general expenses or with the miscellaneous.

We will examine these questions in detail in the second portion of the report, which deals with the classification of working expenses.

In regard to expenditure properly so-called, the statistics should draw a distinction between localized expenses and joint or undivided expenses, with a view to showing the yield of the lines or sections by keeping an account of their traffic. The joint expenses ought necessarily to be apportioned among the lines or sections; the basis of distribution are very diverse, and the results of none are free from all objection. Let us, however, cite the following bases : length of lines, mileages of trains, mileages of vehicles, axles, etc.

E. — Various statistics.

These auxiliary statistics serve either to give an idea of the density of the traffic, or to facilitate estimates of revenue or expenditure.

One can differentiate between the following statistics :

a) *Mileages of locomotives, of trains, of vehicles, distinguishing them according to passengers, goods, vans; axle mileage.* — The figures are derivable directly from the mileage returns, but unfortunately the figures published are not comparable with each other. One finds, indeed, notable differences arising out of the mileages of locomotives running light, ballast trains, service trains, double heading, and shunting which do not figure in the documents of certain systems.

b) *Mileages of staff, engine drivers and stokers, head guards, conductors, brakesmen.* — Few railway systems publish these statistics, the interest of which is evident from the point of view of social questions.

c) *Average composition of passenger, parcels, mixed goods trains; utilization of stock, gross tonnage, net tonnage average, useful load of a train, average tare.* — These statistics, arrived at either directly or by approximation, are extremely important as giving an idea of the general progress of the undertaking; they make possible the revision of the composition of the trains, and the best utilization of the stock.

d) *Expenses per kilometre of train, of locomotive, of vehicle per 1,000 ton-kilometres of goods. Consumption of locomotives; weight and price of coal, oil, grease; averages per locomotive-kilometre, per car-kilometre, per 100 ton-kilometres of goods.* — In France, the system of granting driver's bonuses for exercising economy gives a very great importance to the last-mentioned statistics.

By comparing with the number of kilometres run the consumption ascertained directly from the memorandum-books of the drivers, and the deliveries of fuel and other materials, one arrives at an exact appreciation of the value of the different types of locomotives under normal conditions.

The consumption may be made referable to the locomotive-kilometre or axle-kilometre, either upon the total distance run, or only upon the useful distance; these various methods render comparisons between the systems very difficult, and a unification of method would be highly desirable.

e) *Accidents, delays* — Statistics of accidents according to cause : derailment, imprudence, etc.; according to consequences : death, wounds, fire, etc., and whether to passengers, employees, strangers, are not kept in the same manner in all the systems.

As far as regards the employees, certain systems reckon the incapacity as from the

first day, others wait during a period of absence more or less long. It is necessary, therefore, to be very careful in comparing the figures, the more so as the systems which furnish particulars do not always indicate clearly the definitions adopted.

In general, one compares the number of accidents with the number of passengers carried, but the figures are anything but exact, by reason of the uncertainty as to the composition of the suburban trains, for instance. Here again, unification would clearly be advisable.

f) *Staff. Superannuation funds, pensions, etc.* — Very few systems give an analysis of their staff according to the nature of their employment. The figures would certainly be very interesting.

As regards the superannuation funds, the remarkable report of Mr. Lemercier to the Washington Session of the Congress contains all the data which could be desired in the interests of statistics and actuarial science.

F. — General statistics.

The whole of the statistics which we have just reviewed apply to each of the particular systems, but there is an obvious interest in grouping these according to country and completing by general information such as the following :

Successive position as regards length of the lines, details according to district, or administrative subdivision (canton, state, department, etc.).

General returns of revenue, dividends, taxes collected, averages, etc.

It is necessary, of course, to adopt precautions when comparing the figures of two countries. Averages can give only general ideas, and there is danger in drawing conclusions which may, very often, be found wholly inexact when one goes further into the details of the statistics.

III. — Uniform classification of working expenses.

A. — General remarks.

The examination of the reports, budgets and other documents which have reached us reveals essential differences between the existing methods of classification. It appears very difficult, therefore, to arrive at a uniform international classification of working expenses. Furthermore, although in France the authorities have laid down a uniform scheme for the presentation of accounts, we have discovered, without much trouble, notable divergencies between certain sections and items of the traffic accounts as rendered.

We have previously indicated that, as a general rule, the classification of expenditure was made under five headings (placed, according to the country, in a differen order), viz :

Central administration ;
Working properly so-called, internal and general traffic;
Locomotives and rolling stock;
Maintenance of way and works;
Miscellaneous.

The five groups respond to orders of ideas which are not clearly defined. Taking, for example, the French scheme, we will examine the points which invite discussion.

In principle, as regards each of these groups of expenses, one ought to follow administrative divisions, whether one distinguishes the services according to their general functions, or groups under the same heading the services converging in the same direction, such as the central services, the district and local services.

B — Expenses. — Central administration.

These expenses are made up of general outlays attaching to the working, properly so called, of the system, and of expenses arising out of the apportionment of joint general expenditure connected with the establishment, the working, and even other accounts (private estate, etc.).

In the first-named, one can also class the various rates and taxes, the cost of State supervision, assurances and indemnities in respect of casualities caused by the elements, compensation for accidents, legal costs.

The question is really, in fact, one of general expenses of administration which cannot be localized and charged in expenditure against any one of the four great services : internal and general traffic, locomotives and rolling stock, maintenance of way and works, construction. Nevertheless certain administrations group together all or part of these expenses under the title of " Miscellaneous Expenses." It seems more rational to reserve this denomination for expenses of little importance which will be indicated hereafter.

In this first category are classed, also, in France, the subscription expenses, allowances to superannuation funds, benefit funds, medical service. Would it not be better to charge them in augmentation of salaries? Are not grants to superannuation funds really a portion of salary, saved by the companies, on behalf of their employees?

The question is clearly open to controversy. The charging of these expenses in the general expenditure presents the great advantage of demonstrating *en bloc* their importance, and permitting the insertion in the reports of philanthropic considerations.

In any case, from the point of the international comparison, it is preferable that

they should be kept separate, for the system of pensions and benefits being essentially different in the respective countries, it is necessary to extract them again if they are incorporated in the service expenditure.

Finally, the expenses really indivisible, such as the costs of the directorate, the general management, the general services, the accountants' department, the securities and legal departments, ought to show clearly how they are made up.

Their composition is very different, according to the respective administrations; we have indicated above that the supervision of receipts was often viewed as general expenditure, for it sometimes forms part of the general accounts or constitutes a separate service. Other systems leave it under the authority of the traffic superintendent (internal and general traffic). This method of procedure (French) is open to criticism, and does not appear to merit recommendation.

As regards the apportionment of the general expenses among the various accounts which should bear them, we have pointed out that all the bases were more or less equitable, and that one appeared to adopt a distribution according to the so-called method of cash transactions.

C. — Working expenditure properly so called. — Internal and general traffic.

In these expenses, one can simply separate expenses of staff and of materials, or adopt the following divisions : central services, local services, train services (shunting), station service (traffic) and compensation.

This latter classification is far from being followed by all the systems, but those of which we have particulars revert practically to these great divisions, except as regards compensation expenses, which are sometimes considered as general expenses or applied to the services which have occasioned them. As the major portion of these indemnities proceeds from affairs of management and not of traffic, this distribution does not present great interest.

D. — Expenses of locomotives and rolling stock.

One can imagine a classification into staff and materials, but it seems preferable to effect an apportionment, as in the case of the working expenses, among : central services, local services, locomotives, rolling stock.

In general, this service deals not only with the construction, and the accounts should allow for the division of the general expenses of workshop management between these two categories of expenditure. It is necessary to call attention to the charging of costs of renewal of stock which is made under this expense-heading, when a vehicle is struck out of the inventory of stock in order to be demolished. Some systems charge these liquidations to special liabilities accounts in their balance-sheet, without diminishing their assets : the disadvantage of such a procedure is evident, since it causes to be shown among the assets vehicles which have

disappeared or become useless and definitely discarded. Let us mention that in the locomotive expenses one naturally finds the cost of fuel plus the customs-dues, tolls, etc., which are scarcely ever carried into general expenses.

It does not appear advisable to divide the expenditure of the central and local services wholly between the locomotive expenses and those of the maintenance of stock.

E. — Expenses of maintenance of way and works.

Following the principle previously indicated, the following method of division may be proposed :

Central services, district services, inspection of line, maintenance of track, of fixed material, maintenance of buildings, special repairs.

These various groups of expenditure are not found in all accounts. They appear, nevertheless, to form the minimum distinctions which should be made in registering the expenses of the maintenance by the way and works services.

F. — Miscellaneous expenses.

In this group are classed all the outlays which cannot be attached to any of the preceding services, but the categories which we have come across differ greatly according to the respective administrations.

It has been seen that certain systems include therein (wrongly, we think) subscription expenses classed more frequently among general expenses.

In France, there are charged in this group : hirings of stock, which would be better placed among the charges, or in the expenses of locomotives and rolling stock; land-taxes, which could easily be localized according to service, working, rolling stock, locomotives and way; stamp-duties and expenses and shares department, which are more properly general expenses; stores charges which, being loan charges, ought to be added to the latter; levies for reserve, which are general expenses.

Finally, it would be correct, in our opinion, to class in this group only the expenses of lines leased out in a particular way, although it may be possible as a rule to localize the latter according to service, which would reduce almost to nil the various expenses, the grouping of which has scarcely any utility.

CONCLUSIONS.

To sum up, we consider that statistics do not occupy, in the case of railway systems as a whole, the position to which they are entitled.

Sufficient account does not appear to be taken of the importance of the services which they render, whether by immediate utility in connexion with the accidental variations of traffic, of internal working, etc., or by retrospective returns which indicate the general progress of affairs.

It would be puerile to keep statistics for the mere pleasure of setting up tables of figures, but all those which we have indicated have a definite purpose, and will be of service, directly or indirectly, in acquainting the directors or heads of departments with the results of the working, and the utility of the means adopted to secure the efficacy of the services.

From a purely statistical point of view it would be advisable that the returns should be presented in analogous form by all the administrations, with a view to facilitating comparisons.

Should such a step be determined upon, it would be necessary to proceed methodically, commencing with the unification of the general returns serving as bases for the apportionments : length of lines, mileages of trains, of vehicles, of axles, etc., that is to say, with the statistics which we have named auxiliary.

As regards the uniform classification of working expenses, it woud appear very difficult to arrive at an understanding, since in countries like France, where under a general scheme prescribed by the superior authorities, one notices considerable differences of interpretation. At the most, one can only recommend a classification on the lines of the great administrative divisions : general services, internal and general traffic, locomotives and rolling stock, maintenance of way and works.

APPENDIX I.

Detailed list of questions relating to question XIV.

Note by the reporter.

We feel it our duty to justify, by a few observations, the list of questions we have prepared with a view to dealing with the subject which the permanent Commission of the International Railway Congress has been good enough to entrust to us, with regard to railways in countries other than Great Britain and America.

All railway administrations necessarily endeavour to organize their various services in the most practical and the least costly manner. But their respective positions are far from being identical, and the multiplicity of small points which differentiate them is reflected in the working expenses and the cost of the various units considered.

We will mention particularly, from this point of view, the dissimilarities arising out of the extent of the systems worked, the sections of lines which compose them, their complexities more or less marked, the numbers of stations and yards, the importance of the traffic, its distribution according to kind, the average mileages of the traffic units of the greater or less equilibrium of the traffic up and down, the cost of materials, the standard of salaries, the arrangements as regards leave, the limitation of the working-day of the staff, etc.

One finds oneself, then, face to face with very varying questions of fact, and whatever may be the development given to the statistics, it will always be very difficult to make anything like precise comparisons between the respective systems, on account of the impossibility of freeing these results from the conditions under which the lines are established or worked.

With regard to this very diversity, however, we are of opinion that, all imperfect as they may be, the comparisons cannot fail to be useful, and, in any case, interesting.

But we consider, also, that on account of the expense which the establishment of detailed statistics would involve, the data to be furnished should be confined within limits as simple as possible.

It is in accordance with this impression that we have drawn up our list of questions, which we believe the administrations generally will be able to answer without special trouble or difficulty.

Beyond doubt, many of those administrations possess data more extensive and very interesting. In order to enable us to take account of such data in our report, we express the hope that each administration will be good enough, in explaining to us its system of classification of expenditure, to let us have an enumeration, as complete as possible, of the statistical information at its disposal.

*

QUESTIONS.

I.

System of classification of working expenses adopted by each administration.

The organization of railway administrations includes in the ordinary way four chief services : the central administration or general management, including the secretarial department, the general service and common services, accounts and supervision ; the working service (internal and general traffic) ; the ways and works (permanent way and buildings) service ; the locomotive and rolling stock.

State in what respect the organization of your administration differs from this type.

The working expenses are naturally divisible according to service.

As regards the expenses of each service, these are subject to a certain classification.

Explain the system favoured by your administration, and enumerate, as fully as possible, the expenses included under each heading.

Are the expenses, classed and detailed according to service, also subject ton distribution among the *grande vitesse* and *petite vitesse* traffic, in other words, divided between the passenger train and goods train traffic.

Indicate what is done or could be done in this regard, adding any other information which would appear to you useful or interesting from the point of view of the establishment of the net cost per unit of traffic.

II.

Particulars of lines in operation.

(State the position on 31 December 1907, if possible.)

Length of lines worked.

—	Kilometres.
a) Double lines	
b) Single lines	
Total. . .	
of which kilometres are worked in common with other administrations.	
and kilometres serve goods traffic exclusively.	

Total extent of track ($2a + b$).	kilometres.
Number of intersections linking up the different lines, or, in other words, number of points of junctions of converging lines	

Gradients and curves.

—	Length.	Per cent.
Up and down gradients: of 1 to 5 per mil		
Up and down gradients: above 5 to 10 per mil		
Up and down gradients: above 10 to 15 —		
Up and down gradients: above 15 to 20 —		
Up and down gradients: above 20 to 30 —		
Up and down gradients: above 30 per mil		
Up and down gradients: Level		
Total		
or total equal to the length reckoned as track		
If need be, give the subdivision adopted by the company.		

Straights.

—	Length.	Per cent.
Radius of curves: 200 metres and less		
Radius of curves: more than 200 to 300 metres		
Radius of curves: more than 300 to 500 —		
Radius of curves: more than 500 to 700 —		
Radius of curves: more than 700 metres		
Total		
equal to the length reckoned as track		
If need be, give the subdivision adopted by the company.		

Development of shunting lines and sidings . . . . . | kilometres.

Industrial or private sidings.

—	Number.
Junctions with station or yard lines	
— — main lines	
Total	

Stations and yards, etc.

—	Number.
Stations and yards	
Stoppage-points (in open road, for the passenger service)	
Total . . .	
Exclusive of interior offices (town offices, auxiliary offices).	

III.

Particulars of rolling stock.

(There should be included in the effective force the stock in use, under repair, and in reserve.)

TRACTION STOCK.

—	Effective power on 31 December 1907.
Passenger locomotives	
Goods —	
Composite —	
Stations or shunting locomotives	
Steam or automobile cars	
Motor cars for electric lines	

Locomotives in general.

—	With 1 driving axle.	With 2 driving axles.	With 3 driving axles.	With 4 driving axles.	TOTAL.
Number					
Tractive power in kilograms (1)					

(1) The tractive power of the engines, tangentially to the driving wheels, to be calculated by means of the formula $\frac{6{,}714.5\ P\ d^2\ l}{D}$, in which:

P is the working pressure, in atmospheres;
d — diameter of the cylinders, in metres;
l — length of stroke, in metres;
D — diameter of the driving wheels, in metres.

This formula also gives the work, in kilogrammetres, of the engine per metre run.

Rolling stock.

Stock for passenger trains.

—	Effective power on 31 December 1907.		Total number of seats available.			
	Vehicles in general with or without bogies.	Bogie carriages.	1st class.	2nd class.	3rd class.	Together.
First-class carriages						
Second-class carriages						
Third-class carriages						
Composite carriages						
Luggage-vans						
Covered do						
Other vehicles for passenger trains : boxes, horse-boxes, carriage-trucks, etc.						
Total. . .						

Stock for goods trains.

—	Effective power on 31 December 1907.	Total tonnage.
Covered wagons of 10 tons and less		
— — of more than 10 tons		
Open trucks of 10 tons and less		
— — of 10 to 15 tons		
— — of more than 15 tons		
Special trucks, including those used for the track .		
Covered vans.		
Total. . .		

IV.

General results of the working.

(Indicate the year.)

Average length worked . . . . . | kilometres.

Receipts.

—	Francs.
Receipts from *grande vitesse* traffic or secured by passenger-trains. . . . { Passengers	
{ Luggage and other various traffic.	
Receipts from *petite vitesse* traffic or secured by goods-trains . . . . . { Goods by the ton	
{ Other traffic of various kinds . .	
Receipts other than from traffic	
Total. . .	
If the figures from receipts other than from traffic are relatively high, mention to what they relate and how made up.	

Expenses.

—	Francs.	Per cent.
Central administration and common services		
Working (internal and general traffic).		
Locomotives and rolling stock (renewing included)		
Way and works (renewing included)		
Miscellaneous expenses not classed		
Total. . .		
If the expenses not classed are relatively high, show how they are made up.		

Coefficient of working . . . . . .

STATISTICAL INFORMATION CONCERNING TRAFFIC.

Passengers.

—	1st Class.	2nd Class.	3rd Class.	Together.
Number of passengers.				
Mileage . . . . . Kilometres.				
Receipts . . . . . Francs. . .				
Average { mileage run . Kilometres.				
per passenger. { receipts . . Francs. . .				
Proceeds per passenger-kilom. . Francs. . .				

Goods by the ton or goods in bulk.

Number of tons.	
Receipts . . . . . Francs. . .	
Ton-kilometres.	
Average revenue { per ton . . . . . Francs. . .	
Average revenue { per ton-kilometre . . . . . Francs. . .	
Average mileage run of a ton . . . . . Kilometre .	

If the service freights are charged, indicate this, and give the particulars, if possible, separately.

PARTICULARS OF EXPENDITURE.

Subdivide, if possible, the expenses as follows :

Central administration and general services.

—	Francs.
Remuneration of the staff.	
Pensions and grants to relief and retiring funds.	
Other expenses	
Subdivide, if possible, between the traffic of the *grande* and *petite vitesse* respectively.	
Total. . .	

Working (Internal and General Traffic).

—	Francs.
Salaries, wages, bonuses	
Balance of account for the reciprocal employment of stock and for the use of termini, stations or common sections (1).	
Compensation for accidents, losses and damages	
Other expenditure	
Subdivide, if possible, between the traffic of the *grande* and *petite vitesse* respectively	
Total. . .	

(1) Certain administrations carry the assets balances to revenue and liabilities balances in reduction of revenue.

Locomotives and rolling stock.

—	Francs.
Maintenance and repair of locomotive stock	
— — of rolling stock	
Renewal of locomotive stock (1)	
— of rolling stock (1)	
Salaries and bonuses of engine-drivers, engine-men, firemen and brakesmen . .	
Other salaries and wages	
Fuel for locomotives	
Lubricating materials	
Other expenditure	
Subdivide, if possible, between the traffic of the *grande* and *petite vitesse* respectively.	
Total. . .	

(1) Indicate what is to be understood by renewal. Is it a question of cost of reconstruction or of repairing and replacing demolished stock, or of the value of the latter stock taken out of the inventories?

Way and works.

—	Francs.
Salaries and wages.	
Logs, rails and accessories	
Other expenditure	
Subdivide, if possible, the traffic of the *grande* and *petite vitesse* respectively . .	
Total. . .	

VARIOUS INFORMATION.

Average amount of remuneration, bonuses and compensation included, per employee and per year.

—		Francs.
Working	Platelayers	
	Head guards or conductors	
	Guards	
Locomotives and rolling stock.	Engine-drivers or engine-men	
	Firemen	
	Fitters, joiners, workshop employees	
Roads and buildings	Road-labourers (line keepers)	
Average duration of day of workmen on fixed posts		
— of day of engine-drivers, firemen, etc.		
Number of rest and leave days with continuation of pay : per year and per employee		
The case occurring, give the indications for category of staff		
Average cost of fuel per ton		
— — lubricating materials per kilogram		
— — oak and pine-wood per cubic metre		
— — rails per ton		

Mileage of trains and stock.

Trains.

KIND.	Number of kilometres run upon the administration's own lines.			Number of kilometres run by administration's trains on foreign lines.	Total number of kilometres run by administration's trains.
	The administration's trains.	Foreign trains.	Total.		
	a	*b*	*c* $(a+b)$	*d*	*e* $(a+d)$
Passengers :					
Single heading					
Double heading					
Goods :					
Single heading					
Double heading					
Service trains					
Total					
If mixed trains exist, show how assimilated, or give particulars separately.					

Average inclusive speed per hour { of passenger trains | of goods trains

*

Locomotives.

NATURE OF RUNS.	Number of kilometres run on administration's own lines.			Number of kilometres run by administration's locomotives on foreign lines.	Total number of kilometres run by the administration's locomotives.
	Administration engines.	Foreign engines.	Together.		
	a	*b*	*c* (*a* + *b*)	*d*	*e* (*a* + *d*)
With trains: passengers					
With trains: goods					
With trains: service					
Empty					
Train shuntings					
Station shuntings					
Total					

Indicate how are reckoned the distances run in shuntings for the train service (shuntings in course of route) and for the station service (making up and sorting out of trains).

Average distance run of locomotives per unit of effective power.

(Stock in use, under repair, and in reserve.)

—	Kilometres.
Passenger locomotives	
Goods locomotives	
Composite locomotives	
Station or shunting locomotives	
Steam or automobile cars	
Motor cars for electric lines	
Engines in general	

Number of hours of works of locomotives.

(Those in reserve, in steam, included.)

—	Hours.
For the passenger service	
— goods service	
— station shuntings	

Notify other statistical information considered of interest.

APPENDIX II.

Index number	NAMES OF RAILWAY COMPANY OR ADMINISTRATION.	Replied to questions.	DOCUMENTS ANNEXED.
1	Belgian State Railway.	Yes.	Memorandum of accounts and list of salaries in detail.
2	Alsace-Lorraine State Railway.	Yes.	Report for financial year 1908.
3	Bavarian State Railway	Yes.	
4	Oldenburg State Railway	Yes.	Report for financial year 1907.
5	Saxon State Railway	Yes.	Ditto.
6	Wurtemberg State Railway.	Yes.	
7	Austria, Hungary	Yes.	
8	Baden State Railway	Yes.	Report for financial year 1907.
9	Aussig-Teplitz Railway	Yes.	Working regulations.
10	Austrian Northern Railway.	Yes.	Report for financial year 1907.
11	Austrian Southern Railway.	Yes.	Details of accounts.
12	Hungarian State Railway	Yes.	Note upon the classification of working expenses.
13	Arad-Csanad Railway (Hungary)	Yes.	
14	Belgian National Suburban Railway (1)	No.	
15	Bulgarian State Railway	Yes.	Railway statistics for 1907.
16	Andalusian Railway	Yes.	Note upon the classification of working expenses.
17	Lorca-Baza-Aguilas Railway	Yes.	Ditto.
18	Madrid-Caceres Railway	Yes.	Ditto.
19	Spanish Northern Railway	Yes.	Ditto.
20	French State Railway.	Yes.	Note upon the classification of working expenses and specimen report upon a financial year.
21	Orleans Railway (2)	Yes.	Specimen of budget.
22	French Western Railway (2)	No.	Nil.
23	Paris-Lyons-Mediterranean Railway (2)	No.	Report to shareholders for financial year 1907.
24	Landes Local Railway.	Yes.	
25	State Railway, Algerian lines	Yes.	Specimen report upon a financial year.
26	Lorenzo-Marques Railway	Yes.	
27	Transvaal and Orange State Railway.	No.	Report upon the question submittet.
28	Italian State Railway.	Yes.	Note upon the accounts and administrations organization of the system.

(1) This administration does not work its lines itself.

(2) The replies to the list of questions are incomplete. Reference to statistical documents published by the French Ministry of Public Works.

Index number.	NAMES OF RAILWAY COMPANY OR ADMINISTRATION.	Replied to questions.	DOCUMENTS ANNEXED.
29	Luxemburg Prinz-Heinrich Railway	Yes.	General working accounts.
30	Norwegian State Railway	Yes.	Report upon the working for 1906-1907 and memorandum upon district accounts.
31	Dutch State Railway	Yes.	Working account for 1907.
32	Holland Railway Company	Yes.	Ditto.
33	Samarang-Vorstenlanden Railway (Java)	Yes.	
34	Beira-Alta Railway	Yes.	Note upon the classification of expenditure.
35	Rumanian State Railway	Yes.	
36	Sysran-Wiasma Railway	Yes.	
37	Russian State Railway St. Petersburg	Yes.	
38	Moscow-Vindau-Rybinsk Railway	Yes.	
39	Riazan-Ural Railway	Yes.	
40	Russian North Western Railway	Yes.	
41	Swedish State Railway	Yes.	
42	Stockholm-Rimbo Railway	Yes.	
43	Swiss Federal Railway	Yes.	Rules of accounts. Budget of statistical tables for 1907.
44	St. Gothard Railway	Yes.	
45	Ottoman Railway (1)	No.	

(1) Systems the traffic on which is of little importance.

REPORT N° 4

(North America)

By A. J. COUNTY,

ASSISTANT TO SECOND VICE-PRESIDENT, THE PENNSYLVANIA RAILROAD COMPANY.

CONTENTS.

Railway accounts and statistics in the United States :

a) Railway growth;
b) Governmental regulation;
c) Uniform accounts and statistics prescribed;
d) Uniform classification of revenues, expenses, and statistics;
e) Annual report for the Government;
f) Differences between old and new classifications;
g) Monthly reports for the Government;
h) Governmental purposes in promulgating uniform accounting.

Canadian and Mexican railways :

i) Uniform accounting and statistics.

North American railway accounting :

j) Annual reports and statistics for stockholders.

Operating expenses :

k) Uniform classification;
l) Watching revenues and expenses.

Conclusions.

*

INTRODUCTION.

The inability of the reporter for America on " Statistics " to act in that capacity brought a request to the undersigned in March, 1910, to act as reporter by undertaking the treatment of this important subject. In the busiest part of the year, and with only a few months before the meeting of the International Railway Congress, it is impossible to do the subject justice, so I must confine the limits of this paper to the railways in the United States, Canada, and Mexico. I feel that the conditions under which the work was undertaken should be frankly stated at the outset, and I express my indebtedness to my own associates and friends in and out of the railway field for their cordial co-operation

American Railway Officers have for many years been deeply interested in the formulation and use of proper statistics and accounts, because without reliable statistics, and the knowledge they convey, the railways could not be progressively, efficiently or economically managed.

There were, however, other causes which made accounts and statistics essential and forced their evolution, among which may be mentioned: 1° competition through parallel lines which the laws permit to be built in any section of the country, accompanied by ruinous cutting and falling of rates and fares for the carriage of persons, goods, and property; 2° the recurring tides of great financial and industrial prosperity or depression averaging about one every decade; 3° the great distances covered by the lines, and the physical and climatic hindrances to be avoided, or benefits therefrom to be conserved; 4° the discipline of bankruptcy of those companies which disregarded commercial prudence, or were being financially exploited, and were overtaken by failure, followed by judicial sale and reorganization, requiring full publicity and adequate financial and operating statistics before more funds could be obtained from bankers or investors; and 5° the primary necessity of obtaining a record of the transportation service performed on all Divisions of the railways, so as to control the cost of its conduct, and the ned financial results.

Whatever principles underlie their compilation can best be shown by stating present American practice, accompanied by observations and conclusions as the result of experience so far acquired in the use of the present uniform system. The requirements are twofold—firstly, governmental, and secondly, for the owners, management, and all others interested. Both requirements date from the inception of railways. Usage demanded that reports and statistics for the owners and management should make the greatest advancement, but it required an inflexible mandate from the Government of the United States to submerge all individual railway preferences and place them sailing on the broad sea of uniform accounting and statistics.

Railway accounts and statistics in the United States.

a) Railway growth.

The great development of the United States and the continued prosperity and progress of that country is more largely due to, and more dependent upon, its railways than any other single factor. The expanse of territory occupying 3,000 miles from the Atlantic Ocean to the Pacific Ocean and 2,000 miles from the Great Lakes to the Gulf of Mexico, containing unrivalled agricultural and mineral wealth, was touched only in a few places, and to a limited extent, by the ocean, inland water and canal transportation routes and but sparsely inhabited before the advent of the railway. The railways were therefore welcomed as the true pioneers and the country devoted its energies to their construction as the quickest, most direct, and economical method of bridging the great distances and overcoming the adverse physical and climatic obstacles within its borders.

Prior to 1870 grants of lands, or money and franchises were made, without any important limitations, by the National Government to encourage trans-continental lines across the western territories, and by various States and municipalities, with the object of attracting population to their borders and securing the great commercial rewards and trade routes. The railways quickly spread throughout the country preceding, instead of, as in other new countries, following the settler, and, while the varying tides of prosperity and depression have left great marks on these commercial arteries on which the country is so dependent, as well as on the fortunes of those who invested their money therein and those who directed their operation, they have evolved well rounded and prosperous railway systems and serve a population of between 80,000,000 and 90,000,000 people.

The growth briefly sketched in decades is as follows :

1830	23	miles.
1840	2,800	—
1850	9,000	—
1860	30,000	—
1870	53,000	—
1880	93,000	—
1890	164,000	—
1900	193,345	—

On 30 June, 1909 there were 233,000 miles of railway, which in the year ending on that date had operating revenues of $2,494,000,000, or £500,000,000 sterling; operating expenses including taxes of $1,751,000,000; and net operating revenues of $743,000,000, or £150,000,000 sterling.

b) Governmental regulation.

It is not surprising that well-defined accounting and statistical methods should form a prominent feature in the operation and management of these extensive and privately owned systems, and that the National Government as well as the State Governments should desire to supervise their accounts.

It will be recalled that the United States of America consists of many independent and sovereign States, united by a written Constitution, thereby forming the United States, or National Government, which, in addition to exercising certain powers in all of the States as granted by the Constitution, directly governs the various territories not yet formed into States. While a few railroad charters have been granted

by the National Government in the territories from time to ttme under its control, because State governments did not exist therein, the railroad companies derive their powers and privileges from charters granted by the respective States in which the lines are located and operated, and exercise their powers and privileges subject to the laws of these States. The Railways are owned by individual stockholders who provide the capital therefor by the sale of capital stock, bonds, and other forms of securities, and are constructed, maintained and operated by Directors chosen by the stockholders, and officers and appointed by and subject to the Directors in accordance with the State laws. Nevertheless while privately owned and operated, the transportation business and service so generally affects the entire country by serving its necessity and convenience, that it is rightfully regarded in the nature of a public service and interest, and is therefore subject to regulation by the State, and as hereafter explained, by the National Government. This public interest is not confined to America, for it will be remembered that a large part of the capital was obtained in other countries and therefore these countries are interested in the welfare of American Railways, not only as investors, but also on account of the export of agricultural, mineral, and other products.

Under the Constitution, the National Government is granted the power of regulating commerce with foreign nations and among the several States, so that while all commerce within a State is subject to the authority of that State, all interstate and international commerce is regulated by the National Government. Within this plain constitutional provision: have grown in the past thirty years a vast body of national legislation and judicial decisions. The railroads were so necessary to the growth of the country that little attempt at regulation was made prior to 1870, but by building into new territory and by merger and consolidation the various lines became so extensive, and the population and business of the entire country which they serve have so well kept pace with their growth, that the desire for more specific regulation by the State and National Governments became general. It naturally began in the States, and, as the result of the " Granger Agitation " in the Western States in the 70's, many State Railroad Commissions were appointed, with powers to enforce the laws under which the railways existed, and especially to see that railway rates and service should be reasonable, and open without discrimination to all individuals and communities. Many of these railroad Commissions, and among them some of the most influential, like that of the State of Massachusetts, organized in 1869, possessed only advisory and recommendatory authority, and relied for their effectiveness largely upon public opinion, but gradually the powers of the Commissions have been extended and become mandatory. During the past few years, several of them under the title of Public Service or Utility Commissions, have been given not only mandatory powers as to steam railways, but their authority has been extended to electric railways, telegraph and telephone lines and their accounts, so that a uniform system of accounting might be established, and the results published by the State for the information

of the authorities, the citizens and security holders. The powers of these Commissions extend not only to accounting, but in many cases to approving the issues of stocks and bonds, and other important matters not within the scope of this paper, such as betterment of the transportation service and facilities generally, and the rates to be charged therefor.

c) Uniform accounts and statistics prescribed.

Railway regulation was not long confined to the State authorities, for in the decade ending 1880, the question was given extended consideration by the National Government, but the necessity for national legislation was not apparently ripe, and no decisive action was taken until the passage in 1887 of an Act to regulate commerce, known as the Interstate Commerce Act. This Act marked the first step of the Government to prescribe a uniform accounting system for interstate railways, by a Commission called the Interstate Commerce Commission. Many of the railway companies had observed a general classification of operating expenses, and the principles and practice of railway accounts and statistics had been formulated and many of the Railway Companies published admirable reports for years preceding this Act, but it is from the passage of this law, and the subsequent notable expansion in railways and their revenues, expenses and finances, that the public for the first time sees a definite foundation for the present uniform accounting and statistical system. The provisions of the Interstate Commerce Act of 1887 regarding accounting, required annual reports covering capital issues and payments; physical characteristics; operating, traffic and financial statistics; information as to rates and fares; and the contracts with other railways, and gave the Interstate Commerce Commission the right in its discretion to prescribe a uniform system of accounts.

Regulation by Government Commission was a new feature in the United States, and it should be recorded to the credit of American railways that instead of antagonizing the legislation regarding uniform accounting, they formed the Association of American Railway Accounting Officers in 1888 with officers representing 72,000 miles of railway and convened in the Spring of that year to consider a form of annual report to be made to the National Government, and the Act of 1887 was made effective by the friendly co-operation of the railways, for its provisions could not be enforced on account of the inadequacy of the money appropriated. This co-operation between the railways and the Government still continues, and while naturally the views of the Government and Railway officers have sometimes differed, a great work has been accomplished which could not have been effected in any other way, *i. e.*, that of evolving a uniform classification of accounts so far as it is possible to obtain one. This was no easy task for a country with competitive railway systems widely differing in geographical location, in the standard of their development, and in the character of the through and local traffic and their several interests, and it demanded wide experience, nature judgment, and additional expense to reach sound, broad minded conclusions.

This Act performed good service, but it did not produce absolute uniformity in accounting or statistics. It gave time for ample reflexion, the development of uniform account headings, and the test of experience, and so paved the way for the practice of uniform accounting, but after nearly twenty years, it was natural in this active young country that its provisions should be modified and the powers of the Interstate Commerce Commission extended. This was accomplished by the passing of the Act of 1906, known as the Hepburn Act, which was designed to regulate more important public questions than uniform accounting, but the provisions regarding the latter were materially broadened, and, coupled with heavy penalties for non-observance, which caused little surprise, as the law was passed in the heat of public discussion as the concluding chapter in legislation against railroad rebates.

Under this law of 1906, amending the Interstate Commerce Act of 1887, uniform accounts and statistics are now kept and reported to the Commission by all railroads.

Its general provisions regarding our subject, are that the Interstate Commerce Commission (consisting of seven members appointed by the President of the United State, with the consent of the Senate, to serve for a period of seven years and devote their entire time and attention to the business of the Commission) is authorized to require annual reports from all railways engaged in interstate commerce and to prescribe the manner in which the reports shall be made, require specific answers to all questions upon which it may need information, and to prescribe a time within which all railways subject to the provisions of the Interstate Commerce Act shall have, as near as may be, a uniform system of accounts and the manner in which such accounts shall be kept. The Commission has at all times access to all accounts, records and memoranda, subject to the Act which regulates Interstate Commerce, and it is unlawful for railways to keep any other accounts, records or memoranda than those prescribed or approved by the Commission and the latter may employ Special Agents or examiners with authority to examine any and all accounts, records and memoranda kept by the railways. In case of refusal to keep the accounts, records and memoranda or to submit same to the inspection of the Commission or its authorized examiners, a forfeit of $500 for each offence is recoverable by the Government of the United States.

False entries, mutilation of records, or the keeping of accounts or records other than those prescribed or approved by the Commission, is a misdemeanor and upon conviction in a proper court of the United States, a fine or term of imprisonment or both fine and imprisonment may be imposed.

Examiners (employed by the Commission) are subject to fine and imprisonment if they improperly divulge any facts or information coming to their knowledge.

The annual reports are made under oath for the twelve months ending 30 June in each year, and must be filed before the 30th day of September next following, unless additional time is granted by the Commission. If the reports are not filed or specific answer is not made to any

questions authorized by the provisions of the Act, the railway in default shall forfeit to the United States the sum of $100 for each and every day such default exists. The Commission also has authority to require railways to furnish monthly reports of earnings and expenses, and to impose the forfeiture above provided. The Commission may prescribe the forms of any and all accounts, records and memoranda to be kept by the railways, including the accounts, records and memoranda of the traffic movement as well as of the receipts and expenditures of money.

In this same period, the powers of the State Railroad and Public Service Commissions were also extended, and by co-operation between the State Commissions and the Interstate Commerce Commission, a general scheme of uniform accounting has been established, based on the uniform accounting system previously used and revised with the advice and assistance of railroad officers. The Railways in every reasonable way have tried to observe the system, and assist the Commission, so that the classifications promulgated thereunder may be universally used by all lines, become permanent, and satisfy all essential demands of the governing powers, as well as those who have furnished the money to construct and successfully administer the railroad lines of the country.

With the exception of a few principles, the uniform accounting system adopted by mutual co-operation, and made compulsory by law, will prove practical in working, especially if dominated by good sense and patience on both sides, and if the constitutional principles of railway regulation and supervision, to which the State and National governments are committed, are observed in lieu of railway control or administration apparently sought to be obtained through accounting or other methods, without assuming the responsibility of ownership and management. Under private ownership and governmental supervision and regulation, the railways have grown in less than eighty years to a commanding position, and have been the chief agencies which have populated the country, developed its manufacturing, agricultural, mineral, and other resources, carried prosperity with them, and while their total net revenue has materially increased, their rates to the public have steadily decreased. They have continuously improved the transportation service by capital expenditure ably seconded by the use of surplus income, which corrected the necessary bonus issues of capital stock in their early history for which no cash was paid, and have also borne the constantly increasing burden of various forms of taxation imposed by the very communities which were founded, and their material prosperity secured, by railroad construction and operation. The record of private ownership and governmental supervision judged from any reasonable standard therefore needs no defence.

d) Uniform classification of revenues, expenses, and statistics.

Under the Interstate Commerce Act, as amended in 1906, six classifications have been issued for steam railway covering Operating Revenues; Operating Expenses; Road and Equipment Expenditures for new lines, or important extensions of

existing lines; Locomotive Miles, Train Miles, and Car Miles; Outside Operations, Revenues, and Expenses; Expenditures for Additions and Betterments to existing lines, to which reference is hereafter made. A very clear explanatory text accompanies all of these classifications, showing what should be included in each primary account. The Commission has also issued a form of General Balance Sheet Statement, but this and the Classification of Additions and Betterments, are open to modification, because a few principles have not been disposed of to the mutual satisfaction of the Railways and the Commission.

e) Annual report for the Government.

Monthly and Yearly reports are required, and also reports on special features may be called for. These reports and classifications, which have been fully revised since 1906 and issued by the Interstate Commerce Commission, constitute the uniform accounting system, and reach a conclusion in the tables which from the *Annual Report* to the Commission — hereto attached — marked appendix A.

The requirements of each table (numbered below) in the Annual Report will be examined and in this way the uniform classsification of operating expenses, as well as the principles of statistics of railways in operation will be considered.

1. The name of the Railway Company, with a summary of the laws under which it has been incorporated, and if an amalgated or consolidated company, the name of the various constituent companies.

2. The Director and principal officers.

3-4. The active and inactive corporations controlled by the respondent railway and the nature of that control.

5. Particulars as to stockholders' meetings, closing of stock books, voting rights possessed by the shares; also whether the respondent company is controlled by any other corporation or individual and the nature of such control.

6-7. The name, termini and mileage of every railroad company, the operations of which are included in the report, whether fully or jointly owned, leased, or operated under contract.

8. " Outside Operations " and " Other Properties " covered by the capital of the respondent company, consisting of boat and ferry lines, harbour terminal transfers, cab and omnibus service, hotels, restaurants, dining car service, and other items listed in full in Table 33. The other properties consist of government land grants, coal, lumber, and other business properties not included in the railway lines owned or " Outside Operations ".

9. Railways acquired by respondent company for operation through lease or agreement; and railways assigned to another company for operation through the same medium.

10-14. Statement of capital stock, funded debt, equipment trust obligations, setting forth the various kinds of capital stock, and the dividends declared thereon during the year, also the various kinds of funded debt, whether mortgage bonds, collateral bonds, plain bonds, debentures and notes, income bonds, miscellaneous obligations, and equipment trust obligations (the latter being used to purchase new locomotives and cars) of which a cer-

tain portion of the principal matures every year. It will be noted in these statements of stock and funded debt, that the purpose of the issue and amount realized therefor must be stated; also the total par value of either stock or bonds held by the Company itself, whether in its treasury on in sinking or other funds connected with the corporation.

14. To remind one that all railroads are not profitable, there is a statement of certificates issued while the company is in the hands of a Court Receiver, instead of being operated under the direction of a President or other officer, elected by the stockholders or appointed by the Board of Directors.

14. Current assets and liabilities in details.

15. Security for the various forms of funded or bonded debt, or other fixed obligations, outstanding.

16. Expenditures for Additions and Betterments. They are divided under 32 primary accounts, showing whether same were charged to capital, special funds or to surplus income. These expenditures consist of additions to, or betterments of, the existing railway, its facilities and equipment.

In issuing the Classification of Expenditures for Additions and Betterments, the Statistician of the Interstate Commerce Commission states :

As the Form of General Balance Sheet Statement to be promulgated by the Interstate Commerce Commission to take effect on 1 July, 1909, provides that all expenditures for a new construction and for additions and betterments should be charged to the proper accounts under the caption « Property Owned as Investment, » *viz.*, the railroad and its rolling stock, it is no longer permissible to charge such expenditures to Income, Profit and Loss, or Special Funds *in such a manner as to exclude any expenditure for additions and betterments from the property accounts in the balance sheet.*

Additions and Betterments include additional structures, facilities of equipment not taking the place of anything previously existing, and the enlargment or improvement of existing structures, facilities, or equipment, or the propor portion of the cost of new structures or facilities of an improved or higher class taking the place of others previously existing. Expenditures for additions and betterments amounting to less than $200 (with several exceptions) should be charged to the appropriate accounts under Operating Expenses or Outside Operations, except as otherwise provided in the Classification. In case it becomes necessary directly in connection with betterment or improvement work to abandon any property, the cost of replacing the abandoned property in kind, plus the cost of removal but less the value of salvage, should be charged to the appropriate accounts under Operating Expenses. In case, however, the amount so chargeable is large, and its inclusion in a carrier's operating expenses for a single year would unduly burden the operating expense accounts for that year, the carrier may, if so authorized upon application to the Insterstate Commerce Commision, charge such cost to the Property Abandoned account provided in the Form of General Balance Sheet Statement to be charged off to operating expenses in a series of years. This may be provided for in advance by the reserve account mentioned in the following paragraph.

When property is abandoned and not replaced, the original cost (estimated, if not known) should be credited to the appropriate additions and betterments accounts and charged, less salvage, to Profit and Loss Account, to which should also be charged all incidental expenses directly connected with the abandonment. If so authorized upon application to the Interstate Commerce Commission, however, a carrier may set up operating expense depreciation accounts under "Maintenance of Way and Structures" for the purpose of creating a reserve to which (instead of Profit and Loss (should be charged the original cost, less salvage, of the property (other than land or equipment) abandoned, and all incidental expenses directly connected with the abandonment.

This classification applies exclusively to additions to, or betterments of, existing main and branch lines and their appurtenances and equipment. At the end of the year, the items are merged into Road and Equipment Account.

17-18. Road and Equipment Expenditures. These expenditures are classified into three general accounts (I) Road; (II) Equipment, and (III) General Expenditures, and subdivided into forty-eight primary accounts. The purpose of tables 17 and 18 is to show in detail the expenditures during the year for new main and branch lines, and extensions to existing lines, and additional equipment, with a clear statement showing the amounts thereof charged against capital, and charged to special funds or income, and the total cost to date, with a summarized statement showing cost per mile of railway, under each of the three general accounts.

19-20. The Income Account embraces the grouping of all the accounts covering Income for the year, and shows the gross and net results thereof. The principal feature of the Income Account is that the railway operations, revenues and expenses are kept independent of any other operations owned or directed by the Company. This will be more clearly emphasized in dealing with the various revenue and expense classifications.

21. Profit and Loss Account, in which must be shown in detail all debits and credits of any kind made during the year and the purposes of same.

22. Operating Revenues. It will be noted that these are divided into two general accounts: (I) Revenue for Transportation and (II) Revenue from Operations Other Than Transportation, such as station and train privileges, advertising in stations and on trains, new stands, parcel room receipts, telegraph and telephone service, car service, which is the demurrage charge against shippers for delays in unloading cars, etc., all of which are incidental to transportation, and are not outside or auxiliary operations. The foregoing general accounts are divided into twenty-one primary accounts, including two primary accounts, known as Joint Facilities Accounts, which are provided so as to separate revenues derived by a railroad from the operation of joint tracks, terminals, or facilities, which are either payable to, or receivable from, other companies.

In issuing this Classification of Operating Revenues, the Statistician of the Interstate Commerce Commission states: "It will be observed that the primary accounts are so drawn as to show, firstly, the amount earned for the transportation of

freight, upon which should be based the computation of revenue per ton per mile and revenue per freight train mile; secondly, the amount earned for the transportation of passengers, from which may be computed the revenue per passenger per mile; thirdly, the amount earned from all transportation on passenger trains, from which may be computed the revenue per train mile; and, fourthly, other revenue from transportation service, namely, switching revenue, special service train revenue, and miscellaneous transportation revenue. In addition to revenue from transportation, the Revenue Account includes additional primary accounts which cover revenue from operations incident to transportation, the expenses incident to which are included in Operating Expenses."

23. Shows in detail all deductions from the Operating Revenues, consisting of overcharges, over collections, switching charges, fares refunded, etc. On account of the large amount of work involved, this classification in 23 items has been waived for the present.

24-25. Showing all stocks of other railway corporations owned, and the condition under which they are held by the carrier, *i. e.*, pledged or unpledged, and whether its own stock, the stock of a company whose property forms a part of the operating system, or the stock of a company not forming part of the operating system, the dividends declared thereon and the valuation at which the stocks so owned are carried into the General Balance Sheet.

26-27. Similar tables for bonds.

28. Information required covering ownership of all stocks and bonds other than those of railway companies. The object of tables 24 to 28 is to afford a detailed view of the securities and stocks of all kinds owned by the railway company, and the value at which they are reported to the stockholders, and also to indicate the range of the Company's activities and interests.

29. Sinking, Improvement, Renewal, Injury, and other Special Funds, held or set apart by the company for specific corporate purposes. No funds for the benefit of employees, such as sickness, accident, saving or insurance funds are included.

30-32. Operating Expenses. These expenses are classified under five general accounts (I) Maintenance of Way and Structures; (II) Maintenance of Equipment; (III) Trafic Expenses; (IV) Transportation; and (V) General Expenses. These general accounts are further subdivided into 116 primary accounts as shown in these tables hereto attached. The ratio of the total of each primary account to the general account under which it belongs and to the total Operating Expenses is also shown.

In issuing this important classification, the Statistician of the Interstate Commerce Commission stated: "It is eminently appropriate that public acknowledgment should be made to the Association of American Railway Accounting Officers, and to the standing and special committees appointed by that association, for their hearty co-operation in working out the details of this Classification. In no other way would it have been possible for the Commission to avail itself of that special knowledge and expert experience necessary for the successful accomplishment of the task undertaken."

33. Outside Operations, detailed statement of, *viz.*, hotels and restaurants, ferry and boat lines, harbour terminal transfers, cab and omnibus service, dining, sleeping, and chair cars, etc., showing revenues, expenses and net revenue or deficit of each class. Other Properties, Revenues, Expenses, Taxes and Income or Loss on, such as land grants, coal and lumber properties, etc., in detail.

It did not seem desirable to print the entire classifications of the various Outside Operations, but to illustrate its general scope, the general and primary accounts for Ferry Lines are shown in table 62 of appendix A.

In issuing this Classification, the Statistician of the Interstate Commerce Commission states : " Outside Operations are facilities operated or services rendered by a railway other than those incidental to transportation by rail, the revenues and expenses of which, if included in the carrier's accounts, impair the significance of statistics prepared from such accounts. The purpose of these accounts is to segregate from the accounts of transportation by rail the revenues and expenses of all services not necessarily incident to such transportation and not necessarily rendered by all carriers operating under similar conditions. " Transportation by rail " includes the receipt, transportation, and delivery of traffic, such storage of freight as is necessary to the operation of the railway, all special facilities necessary for the handling of special classes of traffic, such as coal and ore docks, coal transfers, and facilities for the receipt and delivery of live stock, and such car ferries as are actual subtitutes for bridges and tunnels. It does not include local collection and delivery (except switching), or transportation by water, except car ferries as above provided. The rule which should govern in determining what items of expenses should be charged to outside operations is that the rail expense accounts should show the full and true cost of conducting transportation by rail, even though such disposition results in an incomplete or partial statement of the cost of conducting the outside operation. No charge should be made to outside operations if the effect of such charge would be to relieve the rail operation *of an expense that would be charged against it if no outside service were operated.* When a specific charge is made for the service or commodity furnished by the outside operation, such charge consitutes the revenue of the operation.

When the through rate contains an arbitrary division or allowance, intended to cover the service of the outside operation exclusively, such arbitrary division or allowance is to be considered the revenue of the operation and is to be apportioned on local as well as through business. Charges against the operating carrier for services or product should be at cost, and should be credited to the account entitled " Other Operations, Cr.," which has been introduced in operating expenses of outside operations for that purpose. Whenever a credit is made to that account, a charge of like amount should invariably be made to the appropriate operating expense account of the rail department or of some other outside operation. The maintenance of facilities for transportation or other service, or distinct portion thereof, assigned exclusively to an outside operation should devolve upon the outside operation when sepa-

rable from the expense of maintaining the railway. The maintenance of facilities not so separable should be borne by the railway when employed only incidentally by the outside operation and by the outside operation when employed only incidentally by the railway.

34. Rents Receivable from use of joint tracks and joint yards and terminals.

35. Rents Receivable from lease of road and Miscellaneous Rents and other Miscellaneous Income.

36-37. Rents Payable divided as in tables 34 and 35. Other Deductions from Income and result of operation of separately operated properties.

38-39. Hire of Equipment, divided under three headings (A) Equipment Leased, subdivided under Rents Accrued Receivable and Rents Accrued Payable; (B) Equipment Interchanged, divided under I. Accrued on Equipment Borrowed and II. Accrued on Equipment Loaned; (C) Private Cars, showing name of owner, description, number of car miles, rate of compensation, and amount.

40. Taxes and assessments, divided under two headings (A) Company's owned and proprietary lines; (B) Company's Leased and Operated Lines.

41-42. Comparative General Balance Sheet showing changes that have taken place in the financial condition of the company during the year covered by the report (1).

43. Extensions and physical changes of road. Decreases in mileage by straightening line. Leases taken or surrendered. Consolidations or reorganizations effected. New Stocks and Funded Debt issued. Changes in holding of Stocks and Funded Debt. All other important financial changes.

44. Contracts or agreements entered into with other Companies or persons concerning transportation of freight or passengers, such as transportation of mail for the government and with Express, Sleeping, Parlor, and Dining Car Companies, Telegraph and Telephone Companies, etc.

45. Employes, divided into eighteen classes, with number of days worked, total yearly compensation and average daily compensation, with the total salaries distributed between Maintenance of Way and Structures, Maintenance of Equipment, Traffic Expenses, Transportation Expenses, General Expenses, and Outside Operations.

46-47. Traffic and Mileage Statistics, *viz.*

Passenger Traffic:

1. Number of Passengers Carried Earning Revenue,
2. Number of Passengers Carried One Mile,
3. Number of Passengers Carried One Mile per Mile of Road
4. Average Distance Carried, miles,
5. Total Passenger Revenue,
6. Average Amount Received from each Passenger,
7. Average Receipts per Passenger per Mile,
8. Total Passenger Service Train Revenue,
9. Passenger Service Train Revenue per Mile of Road,
10. Passenger Service Train Revenue per Train-Mile.

(1) This form of Balance Sheet has been changed, and a copy of the revised form is inserted in the Appendix.

Freight Traffic :

11. Number of Tons Carried of Freight Earning Revenue,
12. Number of Tons Carried One Mile,
13. Number of Tons Carried One Mile per Mile of Road,
14. Average Distance Haul of One Ton, miles,
15. Total Freight Revenue,
16. Average Amount Received for each Ton of Freight,
17. Average Receipts per Ton per Mile,
18. Freight Revenue per Mile of Road,
19. Freight Revenue per Train-Mile.

Total Passenger and Freight Traffic. — Operating Revenues; Operating Revenues per mile of road and per train mile; similar statistics covering Operating Expenses; net operating revenue or deficit and the operating revenue or deficit per mile of road; Average number of passengers per car mile and per train mile; average number of passenger cars per train mile; average number of tons of freight per loaded car mile and per train mile; average number of freight cars per train mile; average number of loaded and empty cars par train mile; average number of loaded and empty cars per train mile; average mileage operated during the year.

Locomotive Mileage, Car Mileage and Train Mileage in revenue and non-revenue service, covering freight and passenger traffic. (See details in tables 46 and 47, appendix A.)

These are among the most important statistics required by the Commission and are divided into sixty-six separate items.

48-49. Freight traffic movement (Company Material excluded), divided between Products of Agriculture, Animals, Mines, Forests and Manufactures, Merchandise, and subdivided in various commodities, and showing the tonnage originating on the road of the railway, the tonnage received from other carriers, the total tonnage, and the percentage of the total tonnage represented by each commodity and each group of Products.

50-54. Detailed description of equipment (*viz.*, Locomotives, passenger and freight cars, and repair cars), its capacity, the additions and retirements during the year, etc.

55. Mileage of single track, double track, third track, four track, yard track, branches, sidings, etc. Mileage divided by States operated and owned, the new lines constructed and miles of rails used therefor.

56. Tie renewals during year, number, and average price; rail renewals during year, tons, weight per yard, and average price at distributing point. Consumption of fuel by locomotives divided between anthracite and bituminous coal, cord wood, fuel oil, with the miles run and average pounds consumed per mile for locomotives in various classes of service.

57. Accidents of all kinds and how incurred.

58. Characteristics of road by divisions and branches, showing alignment and profile.

59. Bridges, trestles, tunnels, etc., material of which constructed and their maximum and minimum length; overhead highway crossings, overhead railway crossings. Gauge of track. Telegraph Lines along the railway owned or operated by the railroad company, or owned or operated by another company, mileage thereof, etc.

This completes the present annual

report requirements, but I here insert and mark.

60-61. The new form of General Balance Sheet. This has been made partially historical, and laden with many accounting technicalities that prevent it from being easily understood by the investor, and it must inevitably undergo further revision before reaching its permanent form. I also add and mark as number.

62. Ferry Lines, general and primary accounts, as an illustration of what is now required as to each operation outside of Railway Transportation.

f) Differences between old and new classifications.

It will be interesting to note the chief differences between the mandatory new classifications placed in effect since 1906 and the rather optional old classifications, which are :

Firstly. — The separation from railroad results of all Revenues and Expenses not incidental to rail transportation the revenues and expenses of which, if included in rail accounts, would impair the value of statistics compiled therefrom. All revenues and expenses not incidental to railway transportation are embraced under the classification of " Outside Operations."

Secondly. — The net amount paid to any other companies for the use of equipment instead of being an operating expense is now a fixed or obligatory charge against Income — " Hire of Equipment " — because to the extent that it is necessary to hire equipment by paying rental therefor, a company is deficient in investing the capital necessary to furnish sufficient equipment for its own traffic and instead is using the capital of other companies by paying an amount supposed to represent interest thereon. This is not necessarily an evidence of bad management as the line may be part of a through route and dependent upon a connecting line for a large part of its traffic, and therefore not in a position to dictate whose cars shall be used. The company receiving a net payment for the hire of equipment cannot report it among its operating revenues, or as a deduction from operating expenses as heretofore, but must show it as a separate item under " Other Income, " for the converse reason to that given above. It is interest on capital used by others. When the Hire of Equipment accounts, which of course covered principally the interchange of freight cars, were first established, it was ordered that of the per diem charge, which then had been fixed by the railroads at 50 cents, 12 cents thereof estimated to represent the cost of depreciation and maintenance should be either charged or credited to Operating Expenses, but as this amount was entirely an estimate, and as a large number of repairs had to be made entirely at the expense of the using Company, it was afterwards concluded that the whole amount paid or received was more in the nature of a rent than as a reimbursement for repairs or depreciation. Since then this per diem charge has been as low as 25 cents instead of 50 cents, because under depressed business conditions all of the lines had many idle cars.

Thirdly. — Joint Facilities Accounts : These accounts like Hire of Equipment can show either a debit or credit balance,

dependent upon the extent to which a company uses the tracks, terminals or facilities of other companies. Their principal function is to eliminate duplication by showing the entire cost of operating any jointly used terminal, station, yard or tracks in the primary accounts of but one carrier, *viz.*, the owning or operating company, instead of having these charges distributed between primary accounts of all the carriers participating in their use, and in this way show the true cost of operation, regardless of their final distribution through the use of the "Joint Facilities Accounts" of all Companies concerned. They are also designed to show under the primary expense accounts first, the expenses of the company's owned and operated lines, and second the net expense of earning the revenue show. In the United States, it has become a general practice to use part of the tracks, terminals or facilities of other railway companies instead of constructing independent facilities, which would be a duplication of those existing and a waste of capital. Such arrangements generally require the joint user to pay to the owner a proportionate share, based on the number of trains, car and engines, or other traffic units, of 1° interest on the valuation or cost of the tracks and facilities used and 2° of the cost of maintenance, operation and administration and taxes. Under the former methods, the owning company would charge its operating expenses with all of the expenses of maintenance, operation and administration of the joint facilities used with another company or companies, and would include as part of its operating revenues or other income the rental received from the using company, and the using company, and the using company would charge the entire rental so paid; *i. e.*, its share of the interest as well as the operating cost to its own operating expenses or fixed charges or depending upon the judgment of its officers the rental, in whole or in part, might be used to affect the revenues, operating expenses or fixed charges of both companies, the practice being by no means uniform, but the amounts being reflected in the accounts of all companies, being gross and not net, led to considerable duplication. Under the present system of accounting, the amounts received from the use of joint facilities are separated and placed in special primary accounts. The proportion of the interest upon the cost or value of the joint facilities and the taxes received from the tenant company using the same, is not considered as operating revenue, but is reported in the general income account as an item of other income under the heading of "Joint Facilities—Rents" and is regarded as interest return to the owning company upon such portion if its capital as is used by others. In the case of the using company, it is regarded as an obligatory interest charge and shown under the heading "Joint Facilities—Rents," because to that extent it is paying interest upon the capital for tracks, terminals and facilities which another company has provided. The cost of maintenance, operation and administration of such joint facilities is shown in separate itemized debit and credit primary accounts, so that only the net amount paid by a company becomes a part of its operating and maintenance expenses, and if a net amount is received, it is treated as a separate and specific credit, and reduces the

expenses to the amount actually borne.

Fourthly.—Formal Depreciation charges on equipment have been made a part of Operating Expenses; and with the consent of the Commission, Depreciation Accounts may also be established for Maintenance of Way and Structures.

Fifthly. – Premiums realized on the sale of *Capital Stock* must be permanently carried in the Balance Sheet under Capital Liabilities, thereby specifically earmarking the same for Capital Expenditures, and in this way prevent the possibility of their being merged with the Profit and Loss account and used otherwise than as above. This amount can be off-set by any discount suffered on stock, but under the laws of many States, railroad companies are prohibited from selling their stock at less than par.

Discount on Stock must be similarly carried in the Balance Sheet until extinguished by premiums realized on capital stock of the same class. If the stock is to be retired or converted, this can be charged to Profit and Loss or against any premium realized on such stock at the date of its retirement or conversion.

Premium realized on bonds or funded debt must be credited to Income in equal annual instalments during the life of the bond as will extinguish the premium, or credited to Profit and Loss. The credit to Income in any one year must not exceed the amout of the annual instalment.

Discount on Bonds : The discount on Bonds is similarly charged to Income or to Profit and Loss. If the premium realized is greater than the discount on bonds, the latter may be deducted from the premium and the balance shown in the General Balance Sheet.

Discount on Stock or bonds cannot be included in the cost of railway or equipment but must be shown and dealt with as above indicated. The preferable method would appear to be to at once charge the discount against Profit and Loss so as not to leave too much to posterity or trust to realizing premiums.

Sixthly. — Expenditures for Additions or Betterments tothe railway, or its equipment over the cost of replacing in like kind, or original cost, respectively, are recognized as elements of operating cost and can not be charged to operating expenses, but must be shown upon the General Balance Sheet as part of the cost of road or equipment.

The object claimed for the Depreciation Accounts was to guard primarily against an *over*statement or understatement of the net revenues by including such depreciation as part of the operating costs and to spread the charges for replacement evenly over the years rather than have the charge made or omitted as it suited the financial convenience or necessity of the railways, and the purpose of Additions and Betterments Classification was to limit operating expenses strictly to maintenance and operating outlays and depreciation, and so guard against an *under*statement or overstatement of net operating revenues by excluding therefrom additions to, or improvements of, the property or equipment, and as the same time including therein all proper charges for replacement.

I may say here that while the provisions governing Depreciation and Additions and Betterments are, from a theoretical standpoint, reasonably and logically expressed, and the underlying principle of absolute

*

uniformity is preserved, yet from a practical standpoint, a certain amount of arbitrary control is exercised through the medium of these accounts, and proper operating results depend entirely upon their reasonable enforcement. The provisions enter the domain of railway management in deciding what shall constitute an operating expense, and a capitalizable asset. This is especially so when the fact is recognized that all additions and betterments are not proper items for capital issues, and should not from a practical standpoint be carried into the general balance sheet as a capitalizable asset. The accounting rule of the Commission for equipment replacements is open to objection in that it requires that operating expenses shall bear a replacement charge only to the amount of the original cost of the discarded or destroyed equipment, without regard to whether labour or material costs have increased, by this difference understating operating expenses, and also inflating the true value of the equipment. In valuing any asset on the Balance Sheet, it is also desirable that if any deduction is to be made because any part thereof has been paid out of the surplus income, the fact should be clearly shown by deducting such amounts, either specifically or otherwise, before carrying the final cost of these so-called additions to, and betterments of, the road and equipment among the Assets in the General Balance Sheet, and thereby avoid off-setting such payments by a rather obscure item on the Liability side of the Balance Sheet as the accounting rules require.

An accounting system may be correct in theory, so far as operating expenses go, when it provides for operating, maintenance, replacement in kind, and depreciation charges, and requires all beyond these charges to be considered as an addition to or betterment of the property to be shown as a capital asset. Practically this is not the case, because it does not provide a reserve against shrinkages in tariff rates, the trend of which as always been in that direction; business depressions; increased taxes and other Govermental charges; the greater cost of material and labor; or for contingencies based on sound business jugdment and pratices. Practical consideration of all these elements dictates that adequate charges to expenses for maintenance, operation, replacement, and depreciation, must be supplemented by the use of surplus income for such additions and betterments to the property, which do not materially increase the revenues of the railway, materially reduce its operating and maintenance expenses, or substantially add to the value of the property as a whole. Such expenditures should not enter into the Balance Sheet as part of the capital assets, but such part thereof as may be non-productive should be charged off to the total operating and maintenance expenses, before showing the net revenue from transportion operations; such charges to be clearly shown in the accounts so as not to impair the integrity of the operating statistics.

There now remain for examination the mouthly reports (see appendix B).

g) Monthly reports for the Government.

Each report requires a statement of Operating Revenues from Rail Operations, divided between Freight. Passenger, Other Transportation and Non-Transportation;

Operating Expenses for Rail Operations, divided between Maintenance of Way and Structures, Maintenance of Equipment, Transportation Expenses, Traffic Expenses, and General Expenses; Net Operating Revenue (or Deficit) from Rail Operations; Total Revenues, Expenses and Net Revenue (or Deficit) from Outside Operations. One twelfth of Annual Taxes is deducted from the Total Net Revenue, leaving the Operating Income. The number of miles operated on the last day of the month for which the report is made is also required to be shown. The above information is given for the month and for the period since last annual report, compared with similar month and period of previous year.

The information and statistics contained in the respective monthly and annual recort of the railways are compiled by the Interstate Commerce Commission and made the basis of its annual report to the United States Government, which is admirable in its scope and the value of the information conveyed. The Commission has recently established the issue of a monthly report giving the operating results for each system, and a summary for the entire country.

h) Governmental Purposes in Promulgating Uniform Accounting.

The objects, so far as it is possible to ascertain them, sought to be accomplished by the Interstate Commerce Commission in promulgating a uniform statement of accounts were firstly to insure the statement of revenues and expenses of the railroads on a uniform and comprehensive basis, and by monthly reports, special reports and annual reports keep investors, railroad patrons, shippers, traders, and the governmental authorities in possession of the facts; secondly, to exclude from operating expenses the cost of all additions and betterments and carry the same into the General Balance Sheet as part of the cost of the railway or its equipment and at the same time insure the inclusion of all proper charges in operating expenses; thirdly, to satisfy, amid the widespread discussion of rates and the general demand for a flat two-cent rate per mile for passenger traffic, the desire for a uniform system of accounting to campare and separate operating costs, the assumption being that after a reasonable return was paid upon the amount invested in the railroads, or upon a valuation thereof, railroads could be forced by legislative action to lower rates, and that the question of rates was inseparably connected with the cost of each service rendered; fourthly, that the use of railroad bonds as security for the issue of emergency currency in time of stringency might be permitted, provided the Government were in possession of all of the facts regarding the railroads; fifthly, to have the facts regarding railroad revenues and expenses stated in a uniform official method for use in the arbitration of labour disputes; sixthly, so that the practice of governmental regulation through the agency of the Interstate Commerce Commission and uniform accounting directed by that Commission and enforced, if necessary, by periodical examinations by its agents and examiners, would lead to administrative supervision of the railroads as a business affecting the public interest, and for that reason should be controlled.

It is not quite clear to me how that control can be justly and properly exercised

without the responsability attaching to ownership and without conflict with the powers as well as the constitutions and laws of the independent and sovereign States, under which the railroad corporations are created. To realize these objects would further require that, instead of following the constitutional method of reaching judicial conclusions respecting railroads through the courts of law, the Interstate Commerce Commission should be given judicial and inquisitorial, as well as administrative powers. Government by Commission has not yet been sufficiently tested in America to enable one to speak with certainty of the results, nor have the Commissions yet reached the extent of the powers that will doubtless be conferred upon them, but whatever may be the final result — government control or administrative supervision, or what other term may be used — uniform accounting is here to stay, and the few creases that now exist in the structure will be ironed out in good time by the Interstate Commerce Commission and the railways, and no doubt the Commissions of the various States will concur in the final action.

Canadian and Mexican Railways.

i) Uniform accounting and statistics.

The record of what has beeen accomplished in uniform accounting in North America would not be complete without including the Dominion of Canada, which has 24,104 miles of railway in operation, and while in relation to its area it has the smallest, yet in proportion to its population it has the largest railway mileage of any country in the world. These lines carry in a year 33,000,000 passengers which travel an average of 64 miles; 67,000,000 tons of freight, the average haul per ton being 197 miles. The products of agriculture, animals, mines and forests transported in bulk and at low rates, made up 75 per cent of the total freight tonnage. The revenues for the year ending June, 1909, were $145 millions, Operating Expenses, $104,000,000. Of the gross earnings 66 per cent were derived from freight, while the United States Railways derived 69 per cent from freight traffic; Great Britain, 50 per cent; France, 53 per cent and Germany, 65 per cent.

In Canada, the history of railway extension is similar to that of the United States as a great factor in developing the country and as an indispensable agency in populating its extensive area and placing its products in the proper market. The Dominion Government, the Provinces and the municipalities recognized the necessity for adequate transportation facilities and liberally encouraged railways, and Canada is now deriving the benefit of this bounty and it will be a continuously increasing benefit, for that country is yet in the infancy of its agricultural and mineral development.

For over thirty years, no uniform classification of railway accounts existed and comparisons were not possible either between its own railways or those of any other country. In 1907, a uniform accounting system was established and the reporter for America is fortunate in being able to say that with one important exception, *viz* : the inclusion in operating expenses of depreciation, the Canadian form and classifications are uniform with those of the United States. In lieu of

depreciation of course a proper replacement charge is included in operating expenses, and until a more extended practical experience with depreciation has been had in the United States it cannot be said that the Canadian method is excelled. This uniformity must have a material bearing on the relations between the two countries, because nearly all of the larger Canadian lines extend into the United States, while about twenty United States railways are operating in Canada. The Dominion report compiled by the Comptroller of Railway Statistics and made by the Minister of Railways and Canals to the Governor General, states that it took three years to make the system complete — the first to lay the foundation, the second to build the superstructure, and in 1909, the edifice assumed a definite shape.

Therefore, there are railways agregating 257,000 miles in length, working under a uniform classification of accounts and statistics, which could very properly be designated the American Uniform System, in the territory extending north of the Twenty-sixth parallel of latitude and lying between the Atlantic and Pacific oceans, embracing adverse and diverse physical and climatic features, ranging from snow-capped mountain ranges to marshy plains or parched prairies, from tropical to arctic temperatures, with just as varied temperaments of the peoples by whom it is populated in congested cities and scattering settlements. These railways serve a population numbering about 95,000,000; have gross earnings of $2,640,000,000 per annum, expend $1,855,000,000 per annum for operating expenses carry an annual tonnage of 1,600,000,000 tons, with a tonnage mileage of 231,543,000,000 miles, and 923,000,000 passengers travelling in the aggregate 31,116,000,000 miles in one year, and employ 1,584,000 persons. Although a uniform system is promulgated respectively by the national governments of the United States and Canada and in substance by the State governments and Provinces, railway officers will remember that almost in its entirety it is a definite evolution of the study and experience of over forty years of the various railway lines, discussed with, and later adopted by, the governmental bodies with the advice and assistance of railway officers.

So far as Mexico is concerned, a great part of its railway mileage, although originally constructed by private companies, is now owned by the Government, and there are many lines constructed and operated by private companies under concessions by which, at the close of 99 years, the Government takes possession, free of cost, except for the rolling stock which is valued and purchased. No uniform accounting system exists. Generally speaking, the railways follow the system devised by the Country furnishing the capital, modified to suit local conditions. The English capitalists prefer the English system modified by chartered accountants, and the American capitalists, the system used in the United States prior to its revision since 1906, and with the growth of the country it will doubtless be improved.

North American Railway Accounting.

Enough has been said as to broad features of the Uniform Classification and Accounting System, and the requirements to satisfy the governing bodies, and I may

now proceed to railway practice for the use of stockholders and the management.

The railway systems of North America, and I refer to Canada as well as to the United States, endeavour to have the accounts and statistics convey a clear and comprehensive idea of their physical and financial condition, so that heretofore or at present, no corporate or partnership undertakings in this country give to their owners and the authorities more useful or conclusive information. This is done, firstly, through the medium of the annual and monthly reports furnished to the National and State Governments, as previously stated, secondly, by their own published monthly reports of earnings and expenses, and the annual reports of the Board of Directors to the stockholders, also to the various Stock Exchanges which require full reports of the company's affairs before securities will be listed by them and under their rules an annual report to the stockholders must be issued in advance of the annual meeting.

Therefore all safeguards that arise from publicity are enjoyed to the fullest extent by the railways, the investors, the public generally, and the authorities.

j) Annual Reports and Statistics for Stockholders.

While the forms and the contents of the Annual Reports to stockholders differ radically, because each Railway Company deals with its own particular conditions, the statistics and accounts are compiled under uniform rules. The principal features are the Income Account, showing what has transpired in the way of current receipts and expenditures during the year compared with the previous year, and a General Balance Sheet, which shows the status of all accounts at the end of the year. These have always been shown by all Companies, and as the Income Account is the most important index of what has happened during the year, a typical form thereof is given below.

	1909.	Comparison with 1908. Increase or Decrease.
GROSS REVENUE		
Freight revenue		
Passenger revenue		
Mail revenue		
Express revenue		
Other transportation revenue		
Non-transportation revenue		
Total		
Expenses :

Interest on mortgages and ground-rents		
Interest Car Trusts		
Sinking Funds		
NET INCOME		
From which deduct :		
Dividends		
Appropriation for additions and betterments not properly chargeable to Capital Account		
Surplus carried to Profit and Loss Account		

In addition, nearly all of the roads give statistics of mileage and road characteristics over which the transportation service is rendered; of the equipment in which the traffic is conveyed; of the traffic carried; its mileage; train lading; train mileage; tonnage and passengers; tonnage and passenger mileage; average revenue, expenses and net revenue or loss per ton and per passenger per mile; and average revenue, expenses and net revenue or loss per freight and passenger train mile; profit and loss account, the financial returns, the investments of the Company in detail and the income therefrom, and many other useful and interesting statistics, accompanied by comparisons with the previous year which is decidedly important and by explanatory remarks of the President or Executive officers on behalf of the Directors covering the chief features in the report, and calling attention to important matters affecting the Company.

Many railroads publish elaborate statistical tables, of which the following is a sample :

Freight traffic statistics.

—	1909.	*Comparison with 1908.* *Increase or Decrease.*
Miles of road		
Freight revenue (rail)		
Per cent of total revenue		
Number of tons carried

Revenue and expenses per mile of road.*

—	1909.	*Comparison with 1908.* *Increase or Decrease.*
Gross revenue per mile of road		
Operating expenses per mile of road		
Net revenue per mile of road		

Note. — Passenger expenses include charges specially appertaining to that traffic, and also such proportion of the common expenses as its revenue train mileage bears to the total mileage, after charging against Mail and Express revenue their proportion of such common expenses.

Train mile revenue includes revenue from Mail and Express traffic.

Taxes are included in Expenses in computing above statistics.

*Per mile of track is also used.

It is the custom of the larger systems to issue these annual reports in advance of the annual meetings of the Company and as far as practicable to publish synopses thereof in the daily or financial papers so that stockholders before attending the meeting fully understand the Company's condition, have an opportunity to request further information from the management in order to intelligently decide whether their shares will be voted in support of, or in opposition to the management.

I will now pass on to the second part of the subject, *viz.*:

Operating expenses.

k) Uniform classification.

The uniform classification of operating expenses — rather than remain content with merely referring to tables 30 and 32 — Appendix A, and I will also refer to those statistics of railway operation which are taken daily, weekly and monthly, and form the basis for the reports and statistics already referred to, and are the means of directing the attention of the division operating and traffic officers to the results of operating revenues, costs and the extent of the traffic that is being moved, and to strengthen and guide the efforts of the executive officers and management in producing greater efficiency and formulating the policy of the Company.

So much has been well said and written regarding Operating Expenses that I cannot hope to impart any great freshness to the subject. The principles underlying their classification have been understood for many years and were observed by the railways to cover their particular needs in controlling their expenses, but only since 1906 were their needs adjusted to a uniform basis. Again I must extol our necessities beyond our virtues, because the perceptions of railroad men have been quickenedly, firstly, by following the uniform classification and agreeing in its revisions from time to time; secondly, by legislation enacted in a large number of States attempting, irrespective of conditions, to fix the maximum passenger fare at two cents per mile, resulting in extended legal proceedings in which the demonstrationn of the cost of passenger service and a reasonable return on the investment in the passenger business became prime factors. So far as the freight traffic is concerned, the question of rate modifications has been, and is, like the poor — ever with us, and prior to 1906 a greater advance has been made in that branch of the service than in the passenger business regarding questions of cost and average results, but honors are now about even. Thirdly, by the suggested adjustments in the compensation for transporting the mails resulting in a like study for that traffic.

Lastly, I must not forget financial and business depressions which cause all new construction work to be discontinued, and focus the attention of the executives and officers on the curtailment of operating expenses. This has been the situation since the Autumn of 1907 when the railways which had been enjoying a very heavy traffic and had spent considerable sums in increasing their tracks and facilities, suddenly found the pressure of yards crowded with loaded cars changed to one of finding siding room for the storage of empty cars. Since then, the railroad profession has had an opportunity amid the general discussion of accounts with the

Interstate Commerce Commission, rate proceedings before the various State Commissions, and the decrease in traffic, to devote considerable time to the question of a thorough study of operating expenses and operating costs. An undoubted advantage was thereby gained, resulting in a keener effort for greater efficiency in traffic movement, and in further operating economies (aside from wages and material prices), which have not yet reached their limit.

The classification of Operating Revenues as hereinbefore stated is divided into two general accounts: 1° Revenue from Transportation, and 2° Revenues from Operations other than Transportation. The former is sub-divided into eleven primary accounts and the latter which consists of station and train vending privileges, car service, news stand and parcel room receipts, etc., into eight primary accounts. See table 22, appendix A. Operating revenues are finally summarized under four heads. The following percentages in the United States indicate their relative importance for the year ending 30 June 1909 :

Freight Revenue	68·88 per cent.
Passenger Revenue	23·09 — —
Express, Mail, and other Transportation Revenue	7·11 —
Non-Transportation Revenue	0·92 — —

Railway operating expenses are uniformly classified into five general accounts: 1° Maintenance of Way and Structures; 2° Maintenance of Equipment; 3° Transportation Expenses; 4° Traffic Expenses; and 5° General Expenses.

For the year ending 30 June 1909, these expenses required 66·12 per cent of the gross revenue, compared with 69·67 per cent for the previous year, exclusive of taxes. Taxes, however, should be included, in expenses as a separate item, for while a Company and its management and stockholders can exercise supervision over its expenses and fixed charges, and determine to a large measure what they shall be, it has not the same privilege with regard to Taxes, which constitute a lien having precedence over interest on bonds and other obligatory charges, and is a primary expense that must be met before reaching the true net Operating Revenue. In the year mentioned taxes exceeded $89,000,000 and increased the operating ratio from 66·12 to 69·76 per cent of the gross revenue.

The relative importance of the operating expenses in the United States will be indicated in the following percentages of the total operating revenues and the total operating expenses which they required in the year ended 30 June, 1909 :

	Percentage of Operating Revenues.	Percentage of Operating Expenses.
Maintenance of Way and Structures	12 74 per cent	19·27 per cent.
Maintenance of Equipment	15 03 — —	22·72 —
Transportation Expenses	33 73 — —	51·01 - —
Traffic Expenses	2 02	3 06
General Expenses	2·60 — -	3·94 - -

There are other substantial expenses, known as fixed charges, and while not a part of the operating expenses, the results of railway operations cannot be considered as conclusive without keeping them in mind. I refer to interest on funded debt, other obligatory charges, and what must precede them all—taxes, for with the growth of the United States and the extravagance in municipal, state and federal government expenditures, they all are increasing year after year, without any regard to railroad expenses or revenues. The necessity, therefore, of limiting capital expenditures is a duty that the management is obliged to urge upon all departments so that every such expenditure may be made with a definite result in view, either of adding to the company's revenues, materially decreasing its operating expenses, or maintaining its progress and supremacy in its own territory.

Of the operating expenses above indicated, the General Expenses, Traffic Expenses, and probably 40 per cent of the Maintenance of Way and Structures expenses and a similar proportion of the Maintenance of Equipment expenses are constant, and must continue irrespective of the density of the traffic which is to be moved. But 70 or 75 per cent of the Transportation expenses, and at least 60 per cent of Maintenance of Way and Structures and Equipment Maintenance expenses are directly related to, and caused by, train movement.

General Expenses are divided into the following primary accounts, which fully indicate their scope :

Salaries and Expenses of General Officers.
Salaries and Expenses of Clerks and Attendants.
General Office Supplies and Expenses.
Law Expenses.
Insurance.
Relief Department Expenses fort the conduct of Employes' Sickness, Accident, and Death Benefit Funds.
Pensions.
Stationery and Printing.
Other Expenses.
General Administration Joint Tracks, Yards, and Terminals—Dr.
General Administration Joint Tracks, Yards, and Terminals—Cr.

Traffic Expenses, consisting of expenses for obtaining traffic are divided into the following primary accounts :

Superintendence.
Outside Agencies.
Advertising.
Traffic Associations.
Fast Freight Lines.
Industrial and Immigration Bureaus.
Stationery and Printing.
Other Expenses.

This brings us to what is regarded as the real operating expenses of the road, for the maintenance of the railway and structures, for maintenance of equipment, and for transportation expenses, *i. e.*, those connected with train movement. Maintenance of Way and Structures Expenses are divided into the following primary accounts :

Superintendence.
Ballast.
Ties.
Rails.
Other Track Material.
Roadway and Track.
Removal of Snow, Sand, and Ice.
Tunnels.

Bridges, Trestles, and Culverts.
Over and Under Grade Crossings.
Grade Crossings, Fences, Cattle Guards, and Signs.
Snow and Sand Fences and Snow-sheds.
Signals and Interlocking Plants.
Telegraph and Telephone Lines.
Electric Power Transmission.
Buildings, Fixtures, and Grounds.
Docks and Wharves.
Roadway Tools and Supplies
Injuries to Persons.
Stationery and Printing.
Other Expenses.
Maintaining Joint Tracks, Yards, and Other Facilities—Dr.
Maintaining Joint Tracks, Yards, and Other Facilities—Cr.

Expenses for Maintenance of Equipment are divided into the following primary accounts :

Superintendence.
Steam Locomotives—Repairs.
Steam Locomotives—Renewals.
Steam Locomotives—Depreciation.
Electric Locomotives—Repairs.
Electric Locomotives—Renewals.
Electric Locomotives—Depreciation.
Passenger-train Cars—Repairs.
Passenger-train Cars—Renewals.
Passenger-train Cars—Depreciation.
Freight-train Cars—Repairs.
Freight-train Cars—Renewals.
Freight-trains Cars—Depreciation.
Electric Equipment of Cars—Repairs.
Electric Equipment of Cars—Renewals.
Electric Equipment of Cars—Depreciation.
Floating Equipment—Repairs.
Floating Equipment—Renewals.
Floating Equipment—Depreciation.
Work Equipment—Repairs.
Work Equipment—Renewals.
Work Equipment—Depreciation.
Shop Machinery and Tools.
Power Plant Equipment.
Injuries to Persons.
Stationery and Printing.
Other Expenses.
Maintaining Joint Equipment at Terminals—Dr.
Maintaining Joint Equipment at Terminals—Cr.

Transportation Expenses are divided into the following primary accounts :

Superintendence.
Dispatching Trains.
Station Employes.
Weighing and Car-Service Associations
Coal and Ore Docks.
Station Supplies and Expenses.
Yard Masters and their Clerks.
Yard Conductors and Brakemen.
Yard Switch and Signal Tenders.
Yard Supplies and Expenses.
Yard Engineman.
Engine-house Expenses—Yard.
Fuel for Yard Locomotives.
Water for Yard Locomotives.
Lubricants for Yard Locomotives.
Other Supplies for Yard Locomotives.
Operating Joint Yards and Terminals—Dr.

Loss and Damage, Freight.
Loss and Damage, Baggage.
Damage to Property.
Damage to Stock on Right of Way.
Injuries to Persons.
Operating Joint Tracks and Facilities—Dr.
Operating Joint Tracks and Facilities—Cr.

For their own special purposes, railroads further divide many of the primary accounts to keep a close watch upon results.

l) Watching revenues and expenses.

Railroad management, whether in the transportation, traffic, engineering, finance or accounting departments, is a profession, and the larger and well-established railways begin each year, not only with a record of what has been accomplished in the past year, but with an estimate for the current year made after consultation with the officers in charge of the various departments, covering, firstly, the revenues; secondly, a programme of maintenance and replacement expenditures to be paid out of current revenues, including therein proper depreciation charges unless sufficient replacements are currently made to make good the annual depreciation; thirdly, an approximate estimate of other operating expenses; fourthly, an estimate of what should be spent out of current revenues for betterments of and additions to the railway and its equipment, and fifthly, a list of expenditures for new railway construction equipment and real estate, chargeable to capital account. Between such capital expenditures, and the maintenance and replacement items charged in operating expenses, are the expenditures above mentioned in « fourth » for betterments and improvements which run concurrently in making renewals and which it has been the practice of conservatively-managed American roads to provide out of the Surplus Income remaining after the payment of the operating expenses, taxes, interest on funded debt, rentals, and other obligatory charges.

Such betterments and improvements provided out of surplus income, may include such items as the elimination of grade or level crossings, improvements in the grades and alignment of the railway and in the yards and terminal facilities, and equipment, improvements in the design and character of stations, bridges and other structures, when they are betterments which add nothing to the original plant other than the improvement which progress substitutes for the existing plant, or are necessary to keep the railway and equipment up to the standard fixed by the requirements of its business. These should be capitalizable because they do not substantially increase the revenues, materially reduce expenses, or add an important element of value to the property as a whole. This policy has been pursued for so many years that very few of the standard American railways could now be reproduced for the par value of their outstanding stocks and bonds, and it has been the chief means whereby the bonus stock issued used for promotion rewards in their early history (known as watered stock) have been corrected and the integrity of the capital account restored and preserved. It would be a matter of deep regret if this conservative policy should be disrupted and

such expenditures be forced into and retained in capital account by Governmental order.

As the year proceeds, the estimates above referred to are carefully supervised, and additions made to the construction list as the exigencies of present and future traffic demand of expenditures for branch and relief lines, extensions of terminals, yards, tracks, equipment, etc., upon the recommendation of the responsible officer in charge of that branch of the service, and appropriations are voted therefor by the Board of Directors, or other proper Committee or Executive officer.

With the question of expenditures for new railway lines, facilities, and rolling stock definitely and prudently decided, taking into consideration not only present but future requirements, for a railroad is a permanent institution, to produce and sell a product called "transportation," the duty of efficient management is first devoted to the quantity of traffic, its movement and the revenues therefrom, and the cost of its conduct—its operating expenses.

It is the duty of the compiler of statistics to separate the different classes of traffic carried and ascertain, as far as it is possible to do so, whether the service is rendered at a profit of a loss. The railroads are, of course, obliged to continue various train service especially for passenger traffic, and also to carry many items of freight traffic, which on the face of the returns cannot earn enough to pay either their share of the maintenance and operating expenses and other obligatory charges, or their part of the dividend, and must look to the more profitable items for recompense, so that rates are necessarily made on the value of the service rendered and the risk assumed, and not on the cost of transporting each commodity and the classes of passenger traffic. The railways have separated cost to the extent of over two-thirds of their total expenditures between the passenger and freight traffic, respectively, but one-third of the cost, made up of items like maintenance of way, is common to both passenger and freight traffic, and also the taxes, interest on the investment, etc. These common costs have been divided largely on the basis of train mileage, as being the most convenient and, weighing all past and present practical conditions, is perhaps the most acceptable method, although locomotive and car mileage are used by some roads.

The end of this cost accounting will not be reached until the return and cost of every service rendered for both passenger and freight traffic is resolved into units of lading and distance, reflecting the use that has been made of the equipment, and the service rendered on each of the larger Divisions or sections of the railway, and comparisons made with previous years. The railways no longer consist of short lines of single track which in the earlier days could be supervised by a single officer and a small staff, but of large systems with great stretches of four-track lines. These require for their opeartion an extensive and trained organization, and the advancement of the art has been so great, due to the provision of adequate facilities and equipment, traffic density, rate changes, and increased taxes, wages and prices of all kinds, that each branch of the railroad business is becoming specialized and the question of costs and net results in

reaching the stage of a highly-organized industry.

The day of general facts and individual preference in recording results is past, and statistics that fully tell the story, and will bear the light of comparison must be kept to justify the efficiency of the operating officer, whose value is demonstrated by the facility and economy with which the traffic is moved, under the particular or peculiar conditions applying in the part of the railway under his supervision, and the operating plant, consisting of the road, stations, shops and equipment, is maintained and operated.

Those lines with which I am most familiar operate the railway by separating it into divisions, each in charge of a Division Superintendent, having full authority, and responsible to a General Superintendent, who supervises several divisions, and who in turn is responsible to the General Manager and the latter to the Executive officers. There are, of course, many companies which pursue a different plan of organization, and effect results by different methods and different officers from what I describe.

The three branches of the service — Maintenance of Way, Maintenance of Equipment (rolling stock), and Transportation (train movement) — is confided for results to a Division Superintendent having anywhere from 150 to 250 miles of main railway mileage, with branches, or a total track mileage, exclusive of sidings, of from 500 to 750 miles, depending on the traffic density and the district served. Having the largest share of the operating expenses, the operating branch of the service is at all times subject to the greatest crossfire.

This quickened responsibility led to a demand that operating statistics and costs which formerly were compiled in copperplate fashion after the close of the month, should be promptly furnished so that defects could be remedied, for the results of train, car and tonnage movement and costs must reach the man in charge promptly after the train movement occurs, otherwise a railroad in operation may soon deplete its revenues by the heavy expenditures for labour and materials, for unremunerative train and car mileage, and unless the cause is very marked, and the inquiry promptly follows the cause, the management can obtain only a general explanation for bad operating results, instead of the conservation of its funds. Taking the experience in 1907 as an illustration when conditions changed from high water mark of traffic in the beginning of the year to a business depression in the latter part of the year, the operating officer could not immediately decide exactly where and what expenses should be immediately reduced without facts promptly furnished to supplement his judgment. It therefore became a matter for decision as to what statistics were required to give a division officer adequate and prompt control of the situation and to have his expenses well in control.

The Maintenance of Way and Structures and Maintenance of Equipment Expenses, amounting to 42 per cent of the total expenses, are governed, first, by the definite programme allowances made at the beginning of the year, and these or the other programme allowances mentioned are not exceeded except for special purposes approved by the Chief Executive officer in charge of operations, and, if of sufficient

importance and not the ordinary and necessary expenses for upkeep, require approval by the President and the Board. These programme estimates are based on and compared with, similar expenses and costs of previous years on various bases, so that any unusual features of increases or decrease must be fully explained, before being authorized. The changes in Division Superintendents or other officers on a large and active railroad give a fresh view of this question at least every few years. The division or other officer must make his programme estimates based on personal knowledge and on the information given him by his staff, composed of men trained in each branch of the service, and they are subsequently subjected to the scrutiny of the General Superintendent, and, in the case of Maintenance of Equipment Expenses, to that of the respective Superintendents of Motive Power, the General Superintendent of Motive Power, or other proper officer in charge of motive power, and in the case of Maintenance of Way and Structures Expenses, to the Chief Engineer of Maintenance of Way, and finally all such reports are scrutinized by the General Manager. It is clear that after so many trained men have given their experience it is difficult to go far astray in a proper annual expenditure, especially as after its authorization its outgo is carafully guarded, and is subject to the orders of the Division Officer or his responsible assistants in charge of railway and structures, and in charge of the equipment handled in the shops. There is also included as part of the maintenance and operating expenditures a charge to provide for the replacement of the equipment.

So far as expenses for maintenance of tracks, bridges, stations and structures, and maintenance of equipment are concerned, which amount to about 42 per cent of the total operating expenses, they necessarily are related to the extent of the train service, yet in business decreases and does not justify it, a very large part can be deferred, provided the railway and equipment has been heretofore maintained in good working condition and repair.

Little credit has therefore in the past been given for reducing Maintenance of Way or Equipment Expenses because it has been the favourite method of "skimping the property," whereas reduction in Transportation (Train Movement) Expenses is regarded as an indication of efficient management, but now that all expenses are shown in detail in the railway reports and comparison with the previous year, one is enabled to locate the items in which the saving has been effected and prove to a certainty that such has been the case, so that the old time charge of "skimping the property" by neglecting or deferring maintenance or other expenses can no longer be made unless proven by actual results.

In Transportation Expenses, which amount to 51 per cent of the total operating expenses and are so largely dependent upon the train movement, costs of labor and supplies, and traffic density, it is more difficult to effect economies without the closet supervision. In this branch of the service, it is very clear that results must promptly be in the hands of the Superintendent, or labour costs, improper train loading, slow movement, and excessivemileage will seriously interfere with the results. All of this means

*

close watching and the necessity of quickly obtaining unit figures as a warning and comparison.

Since two-thirds of the revenue of the American Railways arises from freight traffic, it is not surprising to find that so much attention is directed to operations in that service. The proper officers with their staff officers and others concerned, have constantly before them telegraphic reports of yard and road conditions; also reports for slow freight trains, showing the number of trains, number of cars, gross lading of each car, train mileage, running times between terminals, average speed, gross ton mileage, *i. e.*, weight of car plus lading, and also the potential ton mileage, which in effect is the maximum which the engine could have hauled under ideal conditions. This is given for comparison with actual gross ton mileage as regards efficiency. As there are many fast freight trains containing lading of a perishable nature which must be run at a fast speed, independent of lading and other conditions, he also has a statement of the gross ton miles of all freight trains and the car mileage, loaded and empty, and the total, and percentage of, loaded and empty cars.

The greatest attention is paid to the lading of the trains so that economical movement may be made and payment of overtime and other expenses avoided. The daily report of the movement of loaded and empty cars past junction or other strategic points, where trains mass in reaching a terminal, showing comparisons with similar previous periods, gives one of the first clues to the business of the day and is about the quickest statistic telegraphed; then comes the weekly return of revenues, divided between freight, passenger, mail and express traffic, the freight often being divided between general merchandise and mineral traffic, and for many roads this weekly information, although approximate, is published in the newspapers. Passenger train lading and results are closely watched, and the Superintendent keeps in close touch with their movement and car mileage. Further, for passenger trains, it is the custom with many roads to take the earnings of each train as often during the month as necessary to insure reliable results and use them in reaching conclusions as to whether trains should be removed or the service supplemented. A statement is furnished monthly of tonnage of principal commodities moved on the divisions. The monthly income account of revenues and expenses for each company and each division, and summarized for the company as a whole, and with the necessary addition of other Income and the deduction of fixed charges and other obligatory payments, gives the first idea of total net income compared with the same month and with a similar period of the previous year. Statistics of cars, tons and passengers moved from the principal stations; statistics of tonnage and passenger mileage, including the average rates, costs and profit or loss per mile from each ton and passenger; and the earnings, expenses and net revenue or loss per train mile. All of these statements are made up by divisions and comparisons and explanations required of the various increases or decreases.

This information at the close of each mont in the hands of each operating official resolves itself down to the following

facts compared with the same month in the previous years : Number of locomotives in service of various kinds and the percentage in good condition, locomotive mileage of all kinds, average locomotive mileage in the various branches of service, average mileage between shoppings for repairs during the month and the two months preceding; passenger car mileage, average number of cars per passenger train, passenger train detentions due to locomotive failures or car failures; freight car mileage, east, west, north and south, loaded and empty, and the percentage of both; average number of cars per freight train; total gross ton mileage; average gross ton per freight train and per freight car; ton mileage; average speed; percentage of passengers and freight trains on time.

The above statement does not require the compilation of operating costs, but closely following same is required a statement of operating costs, worked out upon the following basis :

Coal consumption; consumption of waste and lubricating material; cost of certain passenger (based on 1,000 passenger car miles) and freight (based en 1,000,000 gross ton miles), expenses, including coal for locomotives, wages of enginemen, firemen and trainmen, and supplies furnished trainmen. Cost of certain yard expenses (based on each 1,000 cars dispatched from the yard), including yard locomotives, wages of enginemen, firemen, conductors and brakemen, supplies (except for enginemen and firemen), yard-masters and their clerks, yard switching and signal tenders. Cost of locomotive supplies furnished enginemen and firemen per locomotive in service; engine house expenses per locomotive handled; locomotive repairs per 100 locomotive miles. General movement expenses per 100 locomotive miles, covering lubrication, water, fuel, and other supplies for road locomotives, repairs, renewals and depreciation of road locomotives, engine-house expenses for road locomotives, road enginemen and trainmen. train supplies and expenses.

As this information covers matters controlled largely by the several Division Superintendents and their staff officers, and is compiled in the early part of the month following that in which the expense was incurred, with the approximate expenditures for labour and material, the remedy is largely first in their own hands, but does not remain there, for the higher operating officers are subsequently furnished with the same information arranged to suit their purposes, and explanations as to good or bad results are demanded. The management further exercises its influence on expenditures dependent on many other conditions, such as the present or anticipated financial and industrial conditions. The results of each month's workings of the respective divisions, including all charges whether entirely under the Superintendent's control or not, are sent to the Superintendent and other proper officers of the operating and traffic departments to arouse their responsibility and encourage their efforts to obtain more business, or greater promptness and economy in the movement of the business on the line, and to earn their proper proportion of the fixed charges, dividends that should be paid, and amounts that should be provided for betterments out of income. Is is essential that the statistics of costs to be

put in possession of a Divisional operating officer should first be those over which he has control, that they may apply proper remedies for unsatisfactory performances brought to light by equitable comparisons, but such officers should not be allowed to forget that other charges, such as taxes and interest exist, which are not chargeable to expenses, and that dividends should be earned and paid. Statements of the unit costs of handling tonnage, passengers and baggage at the larger stations are also prepared and sent for criticism to the various officers, and to ascertain why costs are higher or lower at one station than another. On some railways, the chief features of expenditures are also exhibited by chart and diagrams so that vivid pictures as well as figures may drive home the facts. There are now on several of the operating staffs, officers who are charged with the duty of supervising operating costs of all kinds including shop results, and to ascertain by personal examination and conference why better results cannot be obtained, and create a wholesome spirit of emulation among the various officers and divisions to bring about these results. I do not wish to convey the impression that all the railways in the country compile and use all of the foregoing facts, or that the American Railway officer spends the most of his time sitting at a desk, wearing a pair of spectacles, digesting railway statistics, or has any greater love for them than officers in other countries, but in so far as they are of assistance to him, he must, and does, study railway statistics. Constant and personal familiarity with his operating, division, or departmental work, with the assistance of a trained staff, enables him to discern promptly any danger signal of loss of business or excessive cost. As the result of an evolution in a chain of progress of which he is a part, he must and does, profit by statistics, and improves the situation by direct and immediate action taken on the ground as the result of his consideration, or if he cannot do so, is in a position to report to his superior officer reasons for such inability and receives the results of the more extended experience of the latter, who will also probably warn other officers.

I make no reference to the large number of reports concerning the daily operating routine and management because they have become standard, and relate to different features of the railway, ties, rails, its equipment, supplies, shops, signals, and interlocking, tests of all kinds; or to the special studies as new problems arise. These are all taken for granted as being necessary in every country.

The statistics and other information furnished by the officers, agents and employes of each division must be such so that when supplemented by the fixed charges and other obligatory payments and dividends disbursed, the Comptroller, Auditor, or General Accounting Officer may compile thereform the respective monthly and annual reports to the stockholders and to the National and State authorities, and must comprehend the statistics hereinbefore indicated.

Conclusions.

I need not advocate the necessity or advantages of a uniform system of accounts or statistics, for that is behind the railroads in North America, which are devoting their energies to settling the few

remaining points in connection with the prescribed accounts, in such a way as to make the system finally effective and adapted to the varying interests of the weak as well as the strong roads, and to those Compagnies which must observe special charter requirements of the States or Provinces in which they are incorporated. That such advancement has been made is not due to any inherent virtue in American Railway management, but rather to the necessities of development and management already alluded to, which were stronger than any inherent inclinations.

The experience of American railways removes all doubt as to the results achieved by vital statistics, in the hands of those directing and operating the various lines. Rates have fallen, operating expenses, taxes and other charges increased, but the growth of traffic has been handled with greater economy because the operating and traffic officers had full statistics for their constant reference and warning, and these statistics were available for use in various forms very soon after the traffic was moved or the expense incurred. The remedies have been applied in the shape of larger cars, larger train loads, and cars constructed of more durable materials, larger and more scientifically designed freight classification yards and facilities, and the use of a large part of the surplus income for improvements of the grades, alignments and facilities, thereby restricting capital charges and making dividends a permanent feature by deferring them until the condition of the railway and its equipment justified their payment.

In stating these facts, I do not lay claim to any superiority for American methods, nor am I oblivious to the progress in accounting and statistics made by the Railways of other countries, from which we may learn a great deal.

The railroads in North America have by consolidation and affiliations developed into large systems, each embracing from a few thousand to several thousand miles of main running tracks, so that it is impossible to manage them efficiently without the assistance of vital and comprehensive accounts and statistics of the service performed, the volume and character of the business done, the revenues, costs, and net revenues therefrom, and comparisons with other periods compiled in such a way as to aid the efficient direction and management of the property, by quickening responsibility from the highest to the lowest, and from the lowest to the highest officer. In America, there is less time and no more money to be wasted on statistics, unless useful, than in any other part of the world.

a) I take the broad ground, and from the list her ein stated it will be conclusive that no special statistic is believed to tell the whole story without others to supplement and correct it. All statistics kept should demonstrate their utility, and if not demonstrated should be abandoned. Scarcely any two officers derive a like value from a similar statistical statement because of their personal characteristics and service in which they received their training, or because the traffic or problems of their respective divisions differ radically. *b*) No matter what statistics are prepared, it will always require : 1° personal knowledge of the road, its traffic, working conditions all standards to properly interpret them, so that they will act as a guide to, and quicken that responsibility which

results in efficient operating results, and 2° men of ability, experience and loyalty to produce such results. These results cannot now-a-days be achieved until the sense of responsibility and some sort of comparative costs and results are given to foremen, section men, station-masters, yard-masters, agents and train-masters, as well as officers, so as to give them facts covering the cost of labour and supplies involved in their own work, and gradually interest them towards greater efficiency by eliminating waste of materials, time, and effort. This field is still a large and fruitful one, and the costs involved are too large to take chances on results; *c*) Unless statistics reach operating, traffic, and administrative officers within a relatively short time after the operations have taken place, their value is largely lost, and they then serve purposes of record only. This can only be done without duplicating working forces, by the close working of the operating and auditing officiers; *d*) Each operating and traffic officer should have one or two recognized daily statistics summarized by weeks and for the month, agreed upon with the auditing officers, depending upon the character of the division (*i. e.*, whether it is one fed by traffic from other divisions, or is a division located in strictly competitive territory where traffic originates, or has other special features), to keep him in touch with actual operating conditions upon his division affecting operating efficiency and costs. The poorer the railway, the greater the necessity for knowledge of this character, and the greater the necessity for co-operation between operating traffic and accounting officers. When weekly or monthly statistics for a division are furnished, a separation should be made between the statistics, subject to the control of the operating officer from those over which he has no control, or only partial control, and a clear comparison of both sets of statistics given with a simliar month and period in the previous year. Divisional operating officers, through the medium of monthly divisional income and expense accounts, should be given the facts regarding the proportion of the fixed and other obligatory charge of the Company which the earnings of their division are expected to meet, over and above the operating and maintenance charge. The latter quickens a responsibility for earning a good margin over operating expenses, and broadens the view of the officer; *e*) a definite classification must be uniformly observed so that the statistics will at all times convey the same meaning and insure proper comparison with the same items for similar previous periods of the same road or division with itself but not necessarily, however, with those of any other railroad; *f*) that railway revenues and expenses be absolutely separated from all other operations which the company conducts or in which it is interested; *g*) that in no system of uniform accounting should the desire for special information by Railway or Government officials lead them to make arbitrary decisions which strip the operating expenses of everything except bare maintenance charges, and force all above that into the capital accounts. In the interest of the public and the railways the capital accounts should be limited as much as possible, and every encouragement give to make adequate charges to expenses, since all transportation officers naturally try to keep their expenses down rather than up, and so prove their supe-

rior operating methods. Charges in excess of ordinary maintenance can be so shown in the accounts that uniformity will not be outraged. In the desire to standardize accounts, the efforts should be confined to principles and not to details of management, for it must be remembered that each railroad is a problem, and any attempt to mould all railroads to one pattern will eventually be found ill-advised on the part of the regulator, hurtful to the regulated, and an incubuson individual and corporate effiency; *h*) while the American accounting and statistical system is not absolutely perfect, I do not know that it is excelled anywhere. It has proved its benefit to the railroads, and enables investments in railroad securities to be made on a clear knowledge of the physical and financial conditions of the companies.

The railways and their transportation services are deemed to be of a public nature, because the State confers upon them the power to condemn and appropriate land for their purposes subject to the payment of the proper value therefor, and because of the dependence of the community upon the transportation service. So far as the right of eminent domain is concerned, the railways avail themselves of it only as a last resort, after exhausting private negotiations, because of the excessive prices awarded by court juries or commissioners compared with the actual value of the land, but although the railway are privately owned, they are nevertheless granted this right because the use of the land is for the public benefit. The real reasons why the railways are a public benefit are because 1° they enrich the landowner from whom the right of way must be purchased; 2° they create wealth for the State, municipalities, and country through which the lines are constructed by furnishing the means for the development of natural resources, manufactures, and other commodities, quickly and cheaply bring them to the proper market; 3° they increase the revenues of thecommunity by liberal payments of taxes; 4° they constantly enlarge and improve their facilities; 5° they precede instead of follow the settler, thereby stimulating population and greatly extending and serving the wants of the community as well as adding to the ability by which such wants or luxuries are supplied and satisfied; 6° they furnish a reliable avenue for investments of home and foreign monies, and steady employment for large bodies of all grades of labourers, artisans, clerks and professional men; 7° and they open a large and constant market for all kinds of materials and supplies consumed over an extensive area.

Their permanence insures prosperity to the community and while other industries may come and go with only a temporary or partial effect, all suffer when the transportation service ceases or becomes insufficient.

It would be idle to deny that we are living in a new era of progress, in which the standards of living and practice have been materially improved, and railways and other transportation agencies have played no small part in disseminating these higher standards of living and intelligence throughout the world. They minister to the supply and demand of the whole world, break down the barriers of racial prejudice and provincialism, especially the railways in a country of extensive natural resources and population like North America, and nothing can permanently affect

the existence of the railways, the service they render, or the charges for such service, that is not communicated to those countries who look to it as the sources for agricultural, mineral, forestry and manufacturing products and to their citizens who have invested their capital therein.

These factors have created a demand in all countries for the standardization of railways as well as inquiries regarding their operating and financial results, and for the use of standard units by which these results may be conveyed in unmistakable form and substance. Uniformity of accounting and statistics will never admit of an actual and final comparison of one railway with another without a full knowledge of all the facts and conditions, nor will average statistics ever form a reliable a reliable rate-making basis, although in the days of keen competition these figures were a guide to that end and when uniformly kept for a series of years are a great advantage. It would nevertheless be a distinct gain to the railway profession, to those whose monies are invested therein, and to the Governments from which railway powers are derived, if this responsibility were so appreciated that a uniform system of railway reports and particularly a uniform system of operating statistics, so far as the same can be made uniform, were to be adopted by the International Railway Congress. For that purpose, and fully appreciating the difficulties of reaching a conclusion, I respectfully invite attention to the condensed classificatton of operating expenses hereto attached, marked appendix C, used in this country by many railways. It will be noticed that while this classification requires five general accounts, only 44 primary accounts are required in lieu of the 116 primary accounts in the classification for the larger systems. Sufficient experience is now at the disposal of the Congress to prove that a uniform classification of operating expenses is pratical and can by degrees be evolved by the cooperation of all countries, and the greatest benefit of all will be conferred upon the railways themselves by the publication of facts which testify to their skilfull operation and efficient management.

APPENDIX A.

Table I.

HISTORY.

1. Exact name of common carrier making this report.

2. Date of organization.

3. Under laws of what Government, State, or Territory organized? If more than one, name all; give reference to each statute and all amendments thereof.

4. If a consolidated company, name the constituent companies. Give reference to charters of each, and all amendments of same.

5. Date and authority for each consolidation.

6. If a reorganized company, give name of original corporation and refer to laws under which it was organized.

	Sole or joint.	How established.	Extent.	Direct or indirect.	If indirect, name of intermediary through which control is established.	Other parties to agreement for joint control.
Inactive Corporations :						

Table 5.

FACTS PERTAINING TO CONTROL OF RESPONDENT.

1. Date of last meeting of stockholders for election of directors.

2. Date of last closing of stock books before end of year for which this report is made.

3. Total number of stockholders at that date.

4. Has each share of stock on vote?

   If otherwise, explain voting rights.

5. Has any issue of securities contingent voting rights?

   If so, explain character of such rights.

6. Has any issue of securities special privileges in the election of directors?

   If so, explain character of such privileges.

7. Did any other corporation or corporations, transportation or other, control the respondent on June 30, 1909?

   If control was so held state:

   a) The form of control, whether sole or joint;

   b) The name of the controlling corporation or corporations;

   c) The manner in which control was established;

   d) The extent of control;

   e) Whether control was direct or indirect;

   f) The name of the intermediary through which control, if indirect, was established.

8. Dit any individual, association, or corporation, as trustee, control the respondent on June 30, 1909?

   If control was so held, give the names of the trustee and the beneficiary or beneficiaries for whom the trust was maintained.

Table 6.

ROAD OPERATED.

NAME OF EVERY RAILWAY COMPANY THE OPERATIONS OF WHICH ARE INCLUDED IN THIS REPORT.

In giving roads below, observe the following classification and order :

1. Line owned by respondent :
   A. Main line.
   B. Branches and spurs.
2. Line operated by respondent but owned by another corporation, control being secured through stock ownership.
3. Line operated under lease for specified sum.
4. Line operated under contract or agreement, or where the rent is contingent upon earnings or orther considerations.
5. Line operated under trackage rights.

Name.	Termini.		Miles of line for each road named.	Miles of line for each class of roads named.

EXPENDITURES FOR ADDITIONS AND BETTERMENTS.

All expenditures for Additions and Betterments should be charged to one of three accounts : *a*) Capital, *b*) Special funds set aside from income, *c*, Current income : but the same expenditures must not be included in *more than one* of these accounts. In connection with entries of Additions and Betterment is should be observed that.

1. If entered in the column headed « Charged to capital » they must be further included in the column headed « Total cost to June 30, 1909 », on tables 17 and 18.

2. If entered in the column headed « Charged to special funds » they must represent expenditures charged against funds specially set aside out of current income or accumulated surplus. It should be noted that charges to « Replacement funds » are not to be reported in this column.

3. If entered in the column headed « Charged to income » their total should be carried to the Income Account on table 20 and entered as « Additions and betterments charged to income ».

ACCOUNT.	Expenditures during year.			Total.
	Charged to capital.	Charged to special funds.	Charged to income	
1. Right of Way and Station Grounds				
2. Real Estate				
3. Widening Cuts and Fills.

Expenses					*	*	*		*	*	*
Net Revenue	*	*	*						*	*	*
Net Deficit	*	*	*						*	*	*
Total Net Revenue	*	*	*						*	*	*
Total Net Deficit	*	*	*						*	*	*
Taxes Accrued—Table 40 A :	*	*	*						*	*	*
Operating Income	*	*	*		*	*	*		*	*	*
Operating Loss.	*	*	*		*	*	*		*	*	*

The entries in the Income Account should be taken from the pages of the report, if mentioned; otherwise from the books of the company. The Income Account statement is to be presented on the basis of *accruals*, and every item should be given as *accrued* when that is possible.

Operating Revenues: This account includes the total operating revenues as returned on table 22.

Operating Expenses: This account includes the total operating expenses as returned on table 32.

Outside Operations—Revenues: This account includes the revenues from outside operations as returned on table 33.

Outside Operations—Expenses: This account includes the expenses of outside operations as returned on table 33.

Taxes Accrued: This account includes State, county, municipal, school, and other taxing-district taxes assessed on property of all kinds owned by the respondent, or on leased property the taxes or assessments on which are assumed and treated by the respondent as part of its taxes, and so returned in table "A" on table 40. This account should not include taxes on "Other properties" and such taxes or assessments as are properly chargeable to Operating Expenses, Betterments, or Construction.

The charges for the fiscal year may be based on estimates; discrepancies, if any, between the estimates and the actual assessments in the respective States to be adjusted when known. As it is intended that one-twelfth of the estimated annual taxes should be charged monthly to this account, an open account should be kept, to which should be credited from month to month the charges so made, and to which should be charged the actual taxes when paid.

Table 19. (*Continued.*)

INCOME ACCOUNT. (*Continued.*)

Other Income :												
Rents Accrued from Lease of Road—Table 35	*	*	*						*	*	*	
Other Rents—Credits :												
a) Hire of Equipment—Balance—Table 39					*	*	*		*	*	*	
b) Joint Facilities—Table 34					*	*	*		*	*	*	
c) Miscellaneous Rents - Table 35					*	*	*		*	*	*

Dividends Declared on Stocks Owned or Controlled—Tables 24 and 28.	*	*	*						*	*	*	
Interest Accrued on Funded Debt Owned or Controlled - Tables 26 and 28	*	*	*						*	*	*	
Interest on Other Securities, Loans, and Accounts, Miscellaneous Income—Table 35	*	*	*						*	*	*	
Total Other income. . . .	*	*	*		*	*	*					
Gross Corporate Income carried forward. . .	*	*	*		*	*	*					
Gross Corporate Loss carried forward	*	*	*		*	*	*					

Rents Accrued from Lease of Road : This account includes amounts accrued as rents receivable for the use o property owned or controlled by the reporting company and leased to another company as returned on table 35.

Hire of Equipment—Balance : This account includes the credit balance from hire of equipment as returned on table 39.

Joint Facilities : This account includes the purely rental portion, including proportion of taxes, accruing to the respondent from the joint use of tracks, yards, and other facilities owned by it but used jointly with other carriers as returned on table 34.

This account should not be confused with the "Joint-facilities" accounts prescribed in the Classification of Operating Expenses.

Miscellaneous Rents : This account includes all rents not specifically provided for in the three previous rental accounts. It should not be confused with Account No. 18, "Rents of buildings and other property" of Operating Revenues, on table 22.

Separately Operated Properties—Profit : This account includes amounts receivable under the terms of agreements or contracts, whereby the surplus resulting from the separate operation of the property of other companies having an independent corporate existence is receivable in whole or in part. (See table 37.)

Dividends Declared on Stocks Owned or Controlled : This account includes dividends declared during the fiscal year on stocks of other companies owned or controlled by the respondent as returned on tables 24 and 28.

Interest Accrued on Funded Debt Owned or Controlled : This account includes interest accrued on bonds of other companies owned by respondent and eld in its treasury, bonds deposited as collateral, bonds deposited in trust, or bonds controlled through lease or otherwise, the income from which accrues to it; also interest accrued on all other classes of funded debt. This entry should be the total of income from railway and miscellaneous funded debt owned as returned on tables 26 and 28. Interest accrued should not be credited unless the income is reasonably assured by past experience, guarantee, anticipated provision, or otherwise. In other cases, the credit to this account should be based upon the interest actually collected, crediting within the year the portion earned.

Interest on Other Sicurities, Loans, and Accounts : This account includes interest receivable on all securities not provided for in the foregoing account; also interest receivable on notes, loans, bank balances, and other accounts.

Miscellaneous Income : This account includes all other items of income not specifically provided for elsewhere. (See table 35.)

As the remarks governing the treatment of items under "Deductions from Gross Corporate Income" table 20 are the reverse of the foregoing, the same are not repeated here.

Disposition of Net Corporate Income :

Dividends Declared: This account includes all dividends declared out of income earned during the period for which the Income Account is made Whether dividends shall be declared payable out of income for the year or out of the surplus shown in the Profit and Loss account, or both, is left to the discretion of the respondent. The sum of dividends on stock shown on the opposite page and the dividends on stock declared out of surplus shown on table 21 should equal the amount shown as "Dividends declared during year" on table 10.

Additions and Betterments Charged to Income: This account includes all expenditures for additions and betterments made during the current year which are chargeable to income as returned on table 16.

Appropriations to Reserves: This account includes appropriations from corporate income for insurance funds, relief funds, funds for additions and betterments, new lines and extensions, extraordinary emergencies, etc. Expenditures for operating expenses should not be charged against these reserves.

Miscellaneous: This account should show in detail all appropriations from income not otherwise specifically provided for.

Table 33.

SUMMARY OF REVENUES AND EXPENSES OF OUTSIDE OPERATIONS AND OTHER PROPERTIES.

A. — OUTSIDE OPERATIONS.

This table should show the revenues, expenses, and net revenue or deficit of each of the "Outside operations" of the respondent listed on table 8. A detailed statement of these accounts is required in Annual Report Form D—Outside Operations.

DESIGNATION.	Revenues.	Expenses.	Net Revenue or Deficit.
1. Boat Lines			
2. Ferry Lines			
3. Harbour Terminal Transfers			
4. Electric Railways			
5. Express Lines			
6. Cab and Omnibus Service			
7. Sleeping-Car Service			
8. Parlour and Chair Car Service			
9. Dining and Special Car Service			
10. Electric Light and Power Plants			
11. Gas-Producing Plants			
12. Canals			
13. Grain Elevators			
14. Stock Yards			
15. Commercial Telegraph and Telephone Lines			
16. Hotels and Restaurants			
17. Amusement Parks and Resorts			
18. Coal Storage Plants			
19. Gold-Storage Plants			
20. Commercial Ice-Supply Plants			
21. Public Toll-Bridge Service			
Miscellaneous :			

B. — OTHER PROPERTIES.

This table provides for a statement of the revenues, expenses, taxes, and income or loss of the "Other properties" named on table 8.

DESIGNATION.	Revenues.	Expenses.	Taxes.	Income or Loss

Table 34.

RENTS RECEIVABLE.

1° FROM JOINT FACILITIES.

This account is intended for the *rental* portion only of the joint-facility accounts and should not include the cost of maintenance, operation, or administration of joint facilities as provided for by the Classification of Operating Expenses.

Joint Tracks:—Under this heading should be included all rents accrued receivable for the joint use of tracks, including proportion of taxes accrued on property so used payable by other companies.

Joint Yards and Terminals:—Under this heading should be included all rents accrued receivable for the joint use of yards, terminals, and other facilities, including proportion of taxes accrued on property so used payable by other companies.

The total rents accrued receivable for the use of joint facilities should be carried to the Income Account on table 19 and entered as "Joint facilities," under "Other rents—Credits."

Facility Leased.	Location.	Name of Lessee.	Amount.
Joint Tracks:			
Joint Yards and Terminals:			

Table 35.

RENTS RECEIVABLE (*Concluded*).

2° FROM LEASE OF ROAD.

Road Leased.	Location.	Name of Lessee.	Amount.

This account includes amounts accrued as rents receivable for road owned or controlled by the respondent and leased to another company, the terms of the lease or contract granting exclusive use and control for operating purposes

3° MISCELLANEOUS RENTS.

Description of Property.	Location.	Name of Lessee.	Amount.

Under "Miscellaneous rents" should be given all rents accrued receivable for use of properties not otherwise specified under "Rents receivable," and the total should be carried to the Income Account on table 19 and entered as "Miscellaneous rents" under "Other rents—Credits." Only the more important items need to be specified. Minor items may be aggregated. This account should not be confused with Account No. 18, "Rents of buildings and other property," of Operating Revenues on table 22.

MISCELLANEOUS INCOME.

SOURCE OF INCOME.	Gross Income.	Expenses.	Net Miscellaneous Income.

Under this heading should be shown all rents of buildings and other property not used *directly in connection with* the operations of the respondent, and all other items of income not specifically provided for elsewhere. The designation of all items included in "Miscellaneous income" should clearly indicate their character or else they should be explained under "Explanatory Remarks" below.

Expenses for the maintenance of the property from which miscellaneous income is derived, and the expenses incurred in securing that income, should be stated under the heading of "Expenses" and the difference entered in the column headed "Net miscellaneous income."

Table 36.

RENTS PAYABLE.

As the instructions governing these accounts are the reverse of those governing » Rents Receivable » the same are not repeated.

—

IMPORTANT CHANGES DURING THE YEAR.

Here present statements as follows : 1° All Extensions of Road put in Operation. 2° Decrease in Mileage by Line Abandoned or Line Straightened. 3° All other important Physical Changes. 4° All Leases taken or surrendered. 5° All Consolidations or Reorganizations effected. 6° All new Stocks issued. 7° All new Funded Debt issued. 8° All changes in the respondent's holdings of Stocks and Funded Debt. 9° All other important Financial Changes.

Table 44.

CONTRACTS, AGREEMENTS, ETC.

Here give a concise statement of all Contracts, Agreements, Arrangements, etc., with other Companies or persons, concerning the Transportation of Freight or Passengers, which became effective during the year covered by this report. Give the statement in the following order, *viz* : 1° Express Companies. 2° Mails. 3° Sleeping, Parlour, or Dining Car Companies. 4° Freight or Transportation Companies or Lines. 5° Other Railroad Companies. 6° Steamboat or Steamship Companies. 7° Telegraph Companies. 8° Telephone Companies. 9° Other Contracts.

TRAFFIC AND MILEAGE STATISTICS.

ITEM.	Column for Number Passengers, Tonnage, etc.	Columns for Revenue and Rates.		
		Dollars.	Cts.	Mills.
Passenger Traffic :				
1. Number of Passengers Carried Earning Revenue				
2. Number of Passengers Carried One Mile				
3. Number of Passengers Carried One Mile per Mile of Road				
4. Average Distance Carried * miles.				
5. Total Passenger Revenue—Table 22.				
6. Average Amount Received from each Passenger †.				
7. Average Receipts per Passenger per Mile †				
8. Total Passenger Service Train Revenue—Table 22.				
9. Passenger Service Train Revenue per Mile of Road *.				
10. Passenger Service Train Revenue per Train-Mile †				
Freight Trafic :				
11. Number of Tons Carried of Freight Earning Revenue—Table 48				
12. Number of Tons Carried One Mile				
13. Number of Tons Carried One Mile per Mile of Road				
14. Average Distance Haul of One Ton * miles				
15. Total Freight Revenue—Table 22				
16. Average Amount Received for each Ton of Freight †.				
17. Average Receipts per Ton per Mile †				
18. Freight Revenue per Mile of Road *				
19. Freight Revenue per Train-Mile †				
Total Traffic :				
20. Operating Revenues—Table 22				
21. Operating Revenues per Mile of Road *.				
22. Operating Revenues per Train-Mile †.				
23. Operating Expenses—Table 32				
24. Operating Expenses per Mile of Road *.				
25. Operating Expenses per Train-Mile †.				
26. Net Operating Revenue (or Deficit)—Table 19				
27. Net Operating Revenue (or Deficit) per Mile of Road *				
28. Average Number of Passengers per Car-Mile.				
29. Average Number of Passengers per Train-Mile				
30. Average Number of Passenger Cars per Train-Mile *				
31. Average Number of Tons of Freight per Loaded Car-Mile *.				
32. Average Number of Tons of Freight per Train-Mile *				
33. Average Number of Freight Cars per Train-Mile *				
34. Averrge Number of Loaded Cars per Train-Mile *				

METHODS OF OBTAINING AVERAGES INDICATED BY NUMBERED ITEMS.

The items on tables 46 and 47 are numbered consecutively and reference to them is made in the instructions below without specific mention of pages.

* 4. *Average distance carried:*—Divide "2. Number of passengers carried one mile" by "1. Number of passengers carried earning revenue."

†6. *Average amount received from each passenger:*—Divide "5. Total passenger revenue" by "1. Number of passengers carried earning revenue."

†7. *Average receipts per passenger per mile:*—Divide "5. Total passenger revenu" by "2. Number of passengers carried one mile."

8. *Total passenger service train revenue:*—This entry should be the amount shown as a subtotal against this designation on table 22, this being the sum of accounts 2 to 8, inclusive, of "Operating revenues."

†10. *Passenger service train revenue per train-mile:*—Divide "8. Total passenger service train revenue" by the sum of "62. Pasenger train-miles" and "63. Mixed train-miles."

* 14. *Average distance haul of one ton:*—Divide "12. Number of tons carrieb one mile" by "11. Number of tons carried of freight earning revenue."

†16. *Average amount received for each ton of freight;*—Divide "15. Total freight revenue" by "11. Number of tons carried of freight earning revenue."

†17. *Average receipts per ton per mile:*—Divide "15. Total freight revenue" by "12. Number of tods carried one mile."

†19. *Freight revenue per train-mile:*—Divide "15. Total freight revenue" by the sum of "61. Freight train-miles" and "63. Mixed train-miles."

†22. *Operating revenues per train-mile:*—Divide "20. Operating revenues" by "65. Total revenue train mileage."

†25. *Operating expenses per train-mile:*—Divide "23. Operating expenses" by "65. Total revenue train mileage."

28. *Average number of passengers per car mile:*—Divide "2. Number of passengers carried one mile," by the sum of "48. Passenger" and "49. Sleeping, parlour, and observation."

29. *Average number of passengers per train-mile:*—Divide "2. Number of passengers carried one mile," by the sum of "62. Passenger train-miles," and "63. Mixed train-miles."

* 30. *Average number of passenger cars per train-mile:*—Divide "51. Total passenger car-miles," by the sum of "62. Passenger train-miles," and "63. Mixed train-miles."

* 31. *Average number of tons of freight per loaded car-mile:*—Divide "12. Number of tons carried one mile," by "44. Freight car-miles—Loaded."

* 32. *Average number of tons of freight per train-mile:*—Divide "12. Number of tons carried one mile," by the sum of "61. Freight train-miles," and "63. Mixed train-miles."

* 33. *Average number of freight cars per train-mile:*—Divide "47. Total freight car-miles," by the sum of "61. Freight train-miles," and "63. Mixed train-miles."

* 34. *Average number of loaded cars per train-mile:*—Divide "44. Freight car-miles—Loaded," by the sum of "61. Freight train-miles," and "63. Mixed train-miles."

* 35. *Average number of empty cars per train-mile:*—Divide "45. Freight car-miles—Empty," by the sum of "61. Freight train-miles," and "63. Mixed train-miles."

* 36. *Average mileage operated during year:*—This item should fairly represent the mean of the mileage operated during the year (*including* "Line operated under trackage rights"), which should be used in obtaining "Per mile of road" items. If but slight changes occurred, "Total mileage operated" (single track) as returned in Table "A" of table 55 may be used.

Table 47.

FORM OF GENERAL BALANCE SHEET STATEMENT.

ASSETS.

Property Owned as Investment :

1. Physical Property Owned :

1-*A*. Road and Equipment to June 30, 1907 :
- *a*) Road ;
- *b*) Equipment.

1-*B*. Road and Equipment since June 30, 1907 :
- *a*) Road ;
- *b*) Equipment ;
- *c*) General Expenditures.

2. Securities Owned :

2. Securities of Proprietary, Affiliated, and Controlled Companies Pledged :
- *a*) Stocks ;
- *b*) Funded Debt ;
- *c*) Miscellaneous.

3. Securities Issued or Assumed-Pledged :
- *a*) Stocks ;
- *b*) Funded Debt ;
- *c*) Miscellaneous.

4. Securities of Proprietary, Affiliated, and Controlled Companies, Unpledged :
- *a*) Stocks ;
- *b*) Funded Debt ;
- *c*) Miscellaneous.

3. Investments :

5. Advances to Proprietary, Affiliated, and Controlled Companies for Construction, Equipment and Betterments.

6. Other Permanent Investments :
- *a*) Physical Property ;
- *b*) Securities.

Working Assets :

7. Cash.

8. Marketable Securities :

A. Securities Issued or Assumed-Unpledged :
- *a*) Stocks ;
- *b*) Funded Debt ;
- *c*) Miscellaneous.

B. Other Marketable Securities :
- *a*) Stocks ;
- *b*) Funded Debt ;
- *c*) Miscellaneous.

9. Loans and Bills Receivable.

10. Net Traffic, Car Mileage, and Per Diem Balance.

11. Net Balance Due from Agents and Conductors.

12. Miscellaneous Accounts Receivable.

13. Materials and Supplies.

14. Other Working Assets.

Deferred Debit Items :

15. Advances :
- *a*) Advances to Proprietary, Affiliated and Controlled Companies ;
- *b*) Working Funds ;
- *c*) Other Advances.

16. Insurance Premiums Paid in Advance.

17. Taxes Paid in Advance.

18. Discount on Securities Issued :
- *a*) Discount on Stock ;
- *b*) Discount on Funded Debt.

19. Property Abandoned, Chargeable to Operating Expenses.

20. Cash and Securities in Sinking and Redemption Funds.

21. Cash and Securities in Insurance and Other Special Funds.

22. Cash and Securities in Special Trust Funds.

23. Items in Suspense.

Deficit :

SECTIONAL DISCUSSION

Meeting held on 6 July, 1910 (morning).

MR. EVELYN CECIL, VICE-PRESIDENT, IN THE CHAIR.

The President. (In French.) — Mr. Acworth, reporter for Great Britain, will adress the meeting.

Mr. Acworth, *reporter.* — As I appear here as one of the delegates appointed by the British Board of Trade, I ought to say at the outset that the Board of Trade has no responsibility for my report. I was invited by the permanent Commission of Congress to act as a reporter long before I was appointed a delegate by the Board of Trade, and my report is made wholly in my personal capacity. I may say further I sent no *questionnaire* to the companies because, as it seems to me, it was the published statistics alone that concerned an International Congress, for they are the only statistics that can be used for comparative purposes.

I have said that in Great Britain there are no principles of statistics, and there is no uniform classification of expenses. For a long time past complaint has been made both of the insufficiency and of the inaccuracy of the statistics that are published. The responsibility for the present state of affairs rests mainly with the government, which as long ago as 1868 prescribed by Act of Parliament in precise detail the statistics that should be furnished by the companies. In the year 1906, the Board of Trade appointed a Committee, of which I had the honour to be a member, to consider what alterations should be made in the published accounts and statistics of the English railway companies. The new forms proposed by this committee will be found annexed to my printed report. It will be observed that no attempt has been made in them to bring the classification of working expenses into conformity with those in use in other countries. Undoubtedly in my judgment it would have been desirable to do so. But the committee found it impossible: to do so would have meant breaking with the whole past history of English railways, and so radical a step could hardly be made without the active support of the railway companies — support which they were not disposed to give.

As an example, let me give the locomotive accounts. Whereas, in almost every other country the cost of traction appears as one head of cost of operation, in Eng-

land this has always been given, and will continue to be given, in a separate account.

The matter most discussed by the Board of Trade Committee was the question whether the railway companies should be required to furnish ton mile and passenger mile statistics : whether, in other words, record of the length of haul, as well as of the number of tons and passengers hauled, should be recorded. The English companies claim that this information, which of course is given almost everywhere else in the civilized world, is of no value in England. The Committee was divided on this subject. It pronounced by a majority of six to three that this information was valuable. But, in view of the opposition of the railway companies, only three members out of nine were in favour of making it compulsory to furnish the information.

In appendix II of my report will be found tables proposed by the minority to give effect to their recommendations in favour of the publication of ton mileage and passenger mileage.

Appendix I contains the unanimous recommendations of the committee. In view of the fact that the committee which was representative of all classes of opinion was so far unanimous, and that these recommendations have been accepted by the Board of Trade in their entirety, there is every prospect that they will be accepted by Parliament as they stand. A bill for that purpose has been already introduced, and, if and when it passes, the forms in appendix *B* will become the statutory form for accounts and statistics for all the railway companies in the United Kingdom.

The President. (In French.) — Before I pass to the summary of the next report, several of my English colleagues have requested me to recall what Mr. Acworth mentioned at the beginning of his speech, namely that he did not speak as representing the Board of Trade, but in his own proper name.

Mr. Acworth took care to mention this himself, so as to avoid any misunderstanding. Besides, that is the rule here : the reporters give, in their own name, the summary of the information they have collected and make their own personal remarks, but they do not speak in the name of the government or of the country they represent.

As the reporter for the British colonies is absent, I request Mr. Appleyard kindly to give us a summary of Sir Thomas Rees Price's report.

Mr. Appleyard, Central South African Railways. — Sir Thomas Rees Price's report deals with the question of statistics in the British colonies, excluding Canada which has adopted the American system, but including South Africa and Australia.

Unfortunately the Australian railways did not supply the information necessary to make it possible to give an accurate description of their method of work.

The book-keeping of the South African railways much resembles the American book-keeping.

Sir Thomas Rees Price in the first place recognizes that the adoption, by all the railways, of uniform methods for their statistics and traffic returns would be of an inestimable advantage to the organization and administration of railways. It is, however, too much to hope for absolute

uniformity in these statistics now and Sir Thomas Rees Price would like the deliberations of the Congress to result in the future adoption of a standard type, accepted by all the members, for the accounts and the classification of working expenses of railways.

Sir Thomas Rees Price then analyses the principles adopted by the different dministrations of the British colonies, in their statistics.

His report shows that most of the statistics generally drawn up by railways in the British colonies belong to one of the following two classes :

1° Tables or statements (including those giving approximate figures) prepared very soon for the immediate use of the heads of the executive services of the administrations;

2° Statistics of a more permanent character, which usually require longer time for preparation and which are sometimes less useful as regards the organization of the ordinary details of working than as regards the examination of general results and of their tendencies, so as to serve as guide to the administration in considering general administrative and financial questions.

As regards working expenses, Sir Thomas Rees Price records that there is no uniformity in the classification of those expenses adopted by the railways in the British colonies. He thinks that it would be an advantage if the British colonies and the railways in the whole world came to an agreement as to the method of dealing with the expenses connected with :

a) Replacements;

b) Improvements;

c) Capital purposes;

d) Accessory services (for instance catering) in connection with the railways.

The real test of the value of statistics of one class or another is their utility. Sir Thomas Rees Price is of opinion that the statistics of a more permanent character would be of much greater value if, in the interests of uniformity, all the administrations belonging to the Congress came to an agreement about certain points, such as the method of calculating open mileage, train mileage, vehicle mileage, ton mileage, etc. The standardizing of the principal statistical returns and the establishment of a recognized classification, approved by the Congress and adopted generally, would add considerably to the value of the statistics of the different railways and would enable the results obtained by different administrations to be compared.

I have a certain number of papers in my possession which I will with much pleasure submit to those interested in the subject.

The President. (In French.) — As the reporter for America is absent, Mr. Patterson, superintendent of freight transportation, Pennsylvania Railroad, will kindly give a summary of Mr. County's report.

Mr. Patterson, Pennsylvania Railroad. — As Mr. County is unfortunately prevented from attending the meeting, I take his place in order to give you a brief summary of his report. I regret that I am no statistician and hence unable to give details of the different points concerned. But there are present at this meeting a number of eminent American statisticians who will be able to fill this

gap, during the discussion. Mr. County, in this report, comes to the conclusion that the necessity and the advantages of a uniform system of statistics or accounts have become so very apparent during the last ten or twenty years that there can henceforth be no difficulty in imposing, both on weak and on strong roads, and on those companies which must observe special charter requirements, the obligation of keeping certain definite accounts. The different considerations referring to rails and installations set forth in Mr. County's report may serve to make this clear.

The necessity and the advantage of a uniform system of accounts and statistics have for a long time been recognized in the United States. Congress in this connection issued prescriptions by which the Interstate Commerce Commission received the power to enforce very strictly the observance of the legal forms it prescribed. An agreement was come to between the commission and the companies and uniform regulations were adopted applying to all railways.

The reporter believes that no statistics applying to any given point can give useful information without others to supplement and correct it, so as to tell the whole story of all the branches of the service; and general experience upholds this opinion.

No matter how statistics may be prepared, they will always require, in order that they may be interpreted in a comprehensive and intelligible form :

1° Personal knowledge of the traffic and of the working conditions, on the part of those who compile them;

2° Quickness in compiling them, so that they may reach the operating, traffic and administrative officers within a relatively short period after the operations have taken place. This can only be done if there is proper co-operation of the traffic, the operating and the auditing officers;

3° A separation, in each set of statistics, between the facts subject to the control of the operating officer, head of the service for the needs of which this set of statistics is compiled, from those over which he has no control, or only partial control; with a clear definition of both sets of statistics;

4° Finally, however well-founded the desire of railway officers and of the government to obtain a system of uniform accounting may be, this desire must not lead them to prevent wise and prudent measures by arbitrary decisions, like those which strip operating expenses of everything except bare maintenance charges and force all above that into the capital account.

The President. (In French.) — Mr. Bloch, principal secretary of the section, will kindly give a summary of Mr. Barriol's paper, as the latter is absent.

Mr. Bloch, *principal secretary*. (In French.) — Mr. Barriol had to study the question of statistics, as regards all countries, excepting those using the English language. His report, which is very comprehensive, starts with asserting the importance of statistics in establishing an equilibrium between the receipts and expenses. He proposes to divide statistics into four groups :

1° Statistics of cost of establishment, financial resources, charges;

2° Statistics of revenue;

3° Statistics of expenditure, and
4° Various statistics.

As regards the first, Mr. Barriol recommends the following subdivisions :

a) *Installation of lines, including :*

1° General expenses, general costs of management, of central administration, etc. ;
2° Purchase of lands, expropriations, law expenses, etc. ;
3° Earthwork, constructional works ;
4° Permanent way and ballast (materials) ;
5° Station buildings, workshops, stores, depots, telegraphic installations, etc. ;

b) *Rolling stock* ;
c) *Tools and appliances* ;
d) *Stores* ;
e) *Financial resources* ;
f) *Charges* (interest, redemptions, accessory expenses, etc.).

As regards statistics of revenue, Mr. Barriol thinks they should be classified as follows :

a) " *Grande vitesse* " *receipts*, divided into special categories : *passengers* (by class, character of train and rates) ; *luggage*, *dogs*, *cash*, *postal packets*, *horse*, *cattle*, and finally, " *grande vitesse* " *goods*, divided into special categories ;

b) " *Petite vitesse* " *receipts* ; as regards these he thinks the differentiation of the goods can be carried out very fully ;

c) *Miscellaneous receipts* : produce of estates, of lands not utilized, stations held in common with other companies, letting of rolling stock, investments, etc. ;

d) *Statistics of revenue per station and line.*

Passing to the *statistics of expenditure*, Mr. Barriol gives the following five principal heads ; central administration ; working properly so-called ; movement and traffic ; locomotives and rolling stock ; maintenance of way and works. But he recognizes that in practice it is difficult not to come into line, in each railway, with the great administrative questions. He adds that it is difficult to arrive at any international classification, as even in countries like France, where a given system has been specified by the higher authorities, there are differences in detail in dealing with certain articles.

Mr. Barriol would also desire a certain number of detailed statistics to be drawn up for :

Mileages of locomotives, of trains, of vehicles, of staff ;

Average composition of trains of different kinds, utilization of rolling stock ;

Expenses per kilometre of train, of locomotive, of vehicle ;

Accidents, delays, etc. ;

Superannuation funds, pensions, etc.

Finally, Mr. Barriol concludes as follows :

To sum up, it will be found that statistics do not occupy, in the case of railway systems as a whole, the position to which they are entitled.

Sufficient account does not appear to be taken of the importance of the services which they render, whether by immediate utility in connection with the accidental variations of traffic, of internal working, etc., or by retrospective returns which indicato the general progress of affairs.

It would be puerile to keep statistics for the mere pleasure of setting up tables of figures, but all those which we have indicated

have a definite purpose, and will be of service, directly or indirectly, in acquainting the directors or heads of departments with the results of the working, and the utility of the means adopted to secure the efficacy of the services.

From a purely statistical point of view, it would be advisable that the returns should be presented in analogous form by all the administrations, with a view to facilitating comparisons.

Should such a step be determined upon, it would be necessary to proceed methodically, commencing with the unification of the general returns serving as bases for the appointments : length of lines, mileages of trains, of vehicles, of axles, etc., that is to say, with the statistics which I have named auxiliary.

As regards the uniform classification of working expenses, it would appear very difficult to arrive at an understanding, since in countries like France, where under a general scheme prescribed by the superior authorities, one notices considerable differences of interpretation. At the most, one can only recommend a classification on the lines of the great administrative divisions : general services, internal and general traffic, locomotives and rolling stock, maintenance of way and works.

Having given this summary of Mr. Barriol's interesting work, I request the President to allow me to speak, in my own name, about a subsidiary question. The very interesting reports brought to our notice seem to me to consider the question from the point of view of the external statistics, that is to say, from the point of view of the relations between the companies and the shareholders, the public authorities and the economists ; but there is one side of the question which has been omitted, namely that of the internal statistics.

Statistics give the companies a powerful and interesting means for following the working of the services and for enabling the heads of the departments to intervene effectively in order to ensure the proper progress of the work.

I was entrusted with drawing up the report on the question of perishables, and I was surprised to find, in answer to my question as to the results of this traffic, that certain railways, and those by no means smaller ones, declared that they had no statistics.

That seems to me a very extraordinary state of affairs; for a service which works without statistics seems to me like a blind man who does not see where he is going.

Independently of the commercial service, statistics are also an excellent means for checking expenditure.

We will all agree in saying that as a rule railways employés are selected men, that in most cases the employés have every wish to obtain the best possible results, in the first place because they have a feeling of the responsibilities of their duties, in the second because they wish not to call for remark.

But what sometimes prevents them from obtaining good results, is the lack of sufficient information.

Well ! the road to success is to be found in the statistics.

In this connection I can quote two very interesting instances.

Some fifteen years ago, the Orleans Railway started using tables giving for each station, in a very summary form, particulars of the work as well as of the cost of the staff.

The results surpassed all expectations, and we were surprised to find that an

immediate stop in the expenditure of the station staff followed the institution of these tables. Not only was the growth of expenditure abated or stopped, but there were even cases of reduction.

I think, moreover, that this result is due much more to the influence of the station staff itself on its own action than to the control of the head authorities.

The staff has in fact in this way been given information which has enabled it spontaneously to introduce improvements in the service.

We have obtained just as interesting results as regards absence on account of sickness. Among our employés who are generally, as I have already stated, selected men, there are, however, as everywhere, some who are less conscientious. On our railway, full pay is given during days of illness, and there are some doctors who tend to grant an undue length of time of rest to any sick or injured employés. Some years ago, we began to compile statistics of the days of rest granted by each doctor to the sick in his district; and where the average was exceeded we wrote to ask for the reasons for these absences of abnormal duration.

This simple demand for information sufficed to correct the abuses in question and to lead to a diminution in the number of days of rest. Thus the mean number of these days which was 5·9 in 1907, dropped to 5·5 in 1908 and to 5·3 in 1909.

That is a very appreciable result; and accordingly I think that it would be well to extend our studies and investigations to these internal statistics, and I therefore propose to you to adopt the following resolution :

" It is desirable that the investigation and comparison of the statistical methods used by the railway administrations in order to control the work of their employés should be a subject for discussion at one of the next sessions of the International Railway Congress. " (*Applause.*)

Mr. Ftolof, Moscow-Vindau-Rybinsk Railway. (In French.) — Sir Thomas Rees Price, in his report, draws attention to the importance of the division of the expenses between the passenger and the goods services. This is a very difficult problem, perhaps an insoluble one; and all the solutions proposed are based on purely arbitrary assumptions.

I request the permission of the section to bring before them the results I have obtained by applying the theory of probability to this question.

With this object in view, I took the statistics of twenty-five of the Russian lines for a period of three years before the Russo-Japanese war, and I assumed that the total expenditure of each line depended on the following five factors : the length of the line, the number of passenger-train-kilometres, the number of goods-train-kilometres, the number of passenger-axle-kilometres, the number of goods-axle-kilometres.

Applying to these statistical data the method of least squares, I obtained the following results :

The working expenses which do not depend on the train mileage were found to be very small, about 1,000 or 2,000 francs on the average per kilometre (£64 or £128 per mile), out of 30,000 or 40,000 francs of total expenses per kilometre (£1,931 or £2,575 per mile). This result is quite in agreement with the ideas

adopted by Messrs. Colson and Marlio in their investigation of the net cost of extra transportation in the case of the growth of a *regular and important* traffic.

I next found that the net cost of an axle-kilometre was twice as high in the case of passenger trains as in that of goods trains.

I must, however, add that this method cannot be applied when it is a question of a separate railway; but by applying it to a sufficiently large group of railways, as homogeneous as possible, although with traffics of different densities, it seems to me that it will be possible to deduce in each case the rule which will give the basis for the division of the expenses between the passenger and the goods services, even in the case of an individual railway system.

Mr. Timonoff, *vice-president*. (In French.) — I ask to be permitted to draw the attention of the section to two institutions which are of interest from the point of view of railway statistics. In the first place, there is the *Institut international de statistique* which, on the proposal of one of its members, General de Wendrich, who was under-secretary of State at the ministry of ways of communication at St. Petersburg, has appointed a special commission for investigating the question of the statistics of international transports. The work of this commission may prove of great interest to our Congress.

Secondly there is the *Office central des transports internationaux*, at Berne, which instigates the meeting of international conferences; and at one of these conferences it was decided to investigate thoroughly the question of the unification of railway statistics. With this object in view, the Swiss Federal government has entered into diplomatic relations with all countries, two or three years ago already, and at the present time the question of calling a special conference, having as object the unification of railway statistics, is under consideration.

While the work of the *Institut de statistique* is of general and theoretical interest, this is not the same in the case of the work of the conference just mentioned. This conference aims at an object which we all have in view, a practical object.

Railway statistics are not a theoretical science; they are a science which strives to give as accurate information as possible to the railway administrations, in order to make it possible to draw the greatest possible amount of usefulness out of this system of transportation.

The International Railway Congress Association should contribute as much as it can towards the good success of this enterprise, and accordingly I have the honour to propose to you the addition of the following special resolution to the conclusions which you will adopt :

" It is desirable that the initiative already taken hy the Swiss Federal government in calling a special international conference having as its object the unification of railway statistics should result in the establishment, in as short a time as possible, of railway statistics making it possible readily to compare at least the chief principal elements of the working of railways in the different countries. "

Mr. von Zluhan, Wurtemberg State Railway. (In German.). — What you have heard shows beyond doubt that good and

exact railway statistics are of great importance : firstly, to the railways themselves; secondly, to political economy generally. They are certainly one of the most important tests of the economic situation of the different countries. But in order that those statistics may be used for this purpose, it is necessary that the different railway administrations should be able to compare their results with those of other administrations, and if necessary to modify their organization so as to obtain equally favourable results or eliminate unfavourable factors; consequently the statistics must have essentially the same basis. It will be difficult, it is true, to compare from this point of view the railways owned by the State and those owned by private companies.

In Germany, the system of the State railways is by far the most important; but side by side with this there are some privately-owned railways of a certain importance. On the latter, the financial results are of course considered the most important feature, while the State railways, although they attach considerable importance to the working coefficient, can consider, besides the financial results, also the functions and uses of the railways in public life generally.

It has just now been remarked that in more than one country the railway statistics have no uniform basis, or at least that it would be useful to improve that basis. In this respect I may mention that the situation is different in Germany. We have one standard type of statistics for all the German railways. This type includes thirty-two extensive tables. I will only mention the most important ones to you. The tables contain uniform information about : the conditions of ownership and the length, particulars of the profile and the plan, the formation level and the superstructure, the telegraph and signal installations, the number of stations, constructive works and other structures, the maintenance and renewal of the track, the cost of maintenance, of renewal of new constructive works, the number and cost of construction of the vehicles, the locomotives, the passenger carriages, the luggage vans and the goods wagons. They also contain information about the mileage of the rolling stock, the passenger traffic and the goods traffic, the original cost and the expenditure on insurance against sickness and the grants made to employés in cases of accidents while at work and of incapacity. Finally, the financial results, the receipts and expenses, are given in detail. There are also, for all the German railways, standard book-keeping regulations concerning receipts and expenses.

Just as in the case of the *German* railways, we have uniform statistics for the *Verein* which, as you know, includes not only the German railways, but also the Austrian and Hungarian State railways and some other lines in connection with Germany, Austria and Hungary. These statistics also include, under five or six principal headings, like the German railway statistics, all the important particulars relating to the operation of the railways, the receipts and the expenses.

These statistics afford us very valuable assistance; they offer the advantage that they make it possible for all the German railways and all the *Verein* railways to compare their results together accurately.

I thus arrive, like the previous speaker,

at the conclusion that general statistics, common to all the railways, drawn up as specified by the Permanent Commission, are to be recommended, for as I have already said, they will enable the administrations accurately to compare their working conditions with those of other railways and to make modifications and improvements in their system of working.

In order to make such a comparison possible, it is necessary for the statistics to have a common basis, as far as the most essential points are concerned. Perhaps, if I may venture to make the suggestion, the German railway statistics might supply a suitable basis. Moreover, statistics will best allow the comparison of the conditions of the different administrations, if it is based, as far as possible, on statistical railway units.

Then also much importance must be attached to the regular and quick publication of the statistics, for they can only be really useful if this double condition is observed.

Sir Charles Owens, London & South Western Railway. — It gave me great satisfaction to find this important subject included in the programme of the Congress. No railway administration can attempt to carry on its business without adequate and proper statistics, but my personal experience forces me to the conclusion that statistics which might be of primary importance in one country were not at all necessary or of any importance in another country. I do not believe it possible to obtain a uniform system of statistics for all railways. I agree with what has been stated in the reports of Mr. County and Sir Thomas Rees Price.

With regard to the ton mile, it was stated before a committee twenty-five years ago by Mr. Grierson, than whom England had had no more experienced or able railway manager, that as regards the ton mileage statistics they had been tried for years and found unsuitable to English conditions and therefore absolutely useless. For that reason they were abandoned. These statistics have been tried not only by the Great Western Company, with which Mr. Grierson was associated, but by the London & North Western Company, and both companies abandoned them as being useless for the purpose of reflecting the working conditions on English railways. It is possible to have too many statistics, and I myself have had experience of keeping statistics which were never used.

Another consideration is that statistics when applied by the ill-informed are inevitably misleading. It is necessary when attempting to apply detailed statistics that they should be handled by a practical man to whom the conditions of working are known. In connection with American railroads, there is a restriction upon the amount which may be charged to revenue for betterment purposes. In England, on the other hand, nearly every company has a specific sum below which all improvements in the line are charged to revenue. In the case of the London & South Western Company, all improvements, which cost less than £200 are paid out of revenue, and some companies pay amounts up to £500 out of revenue. English railway companies recognize the broad principle that improvements up to a certain amount ought to be borne, not by capital, but by revenue, and I think this is a sound financial policy.

The question of the ton mile was discussed at great length before a meeting of the Railway Accountants' Association in London. It was thought that the ton mile might prove a basis for making rates, but when it was pointed out that the average rate per ton of millinery and coal would hardly give you a fair basis to decide upon the rate for steel rails, that idea died.

I must now turn to Mr. Acworth's paper. Mr. Acworth is an old friend of mine, and I hope that he will forgive me if I say anything which is unkind, but I am compelled to say a few words in vindication of English railway practice after the charges made by Mr. Acworth in his report. Mr. Acworth says he does not represent the Board of Trade, and he certainly does not represent British railway companies, so that I am forced to the conclusion that Mr. Acworth represents Mr. Acworth. Mr. Acworth starts by saying that in the United Kingdom there are no principles of statistics of railways in operation. The truth is that Mr. Acworth has a liking for one particular set of principles, and because he does not find them he assumes there are no principles, much in the same way as a man who with a liking for geraniums, going into a garden and finding only roses blooming, comes back and says there are no flowers in the garden. How does his statement that there are no principles of statistics in operation, reflect upon the Board of Trade who have the power to insist upon statistics? How does it reflect upon the eminent commercial men who form the Boards of Directors of railway companies, and how does it reflect upon the practical railway men who have grown up in the work, and know its needs? It is preposterous to state that there were no principles in railway accounting. I must appeal to the statement in Mr. Acworth's own report, in which he says that in the year 1868 an Act of Parliament was passed which requires all railway companies to prepare and publish half year by half year a report with accounts and statistics according to forms laid down in detail by the Act itself. To say that statistics of that sort could be produced and blue books compiled by a system in which there are no principles was to say what is, to my mind, an apparent absurdity.

Then again Mr. Acworth talks about maintenance-of-way expenditure being subdivided under four heads, and he quotes a statement made by the chief engineer of my own company that it is a matter of pure accident under which of those heads any particular item is put. The statement to which he alluded was made in a lecture delivered to the railway students of the London school of Economics, and in that same lecture the lecturer referred in some detail to the care exercised in the compilation of railway accounts. The lecturer said :

> Such principles as the above can be, and are being followed most carefully and with the most satisfactory results by British railway companies. Every unit of responsibility from which expenditure originates, whether it be the working party under a supervising foreman, engaged upon the maintenance of a section of railway, or whether it be the office of the head of the department, is classified as the whole or part of an accounting group. If a part only, there will be a further sub-classification. From these foundations figures upon which the whole account is built, right up to the total summary every item of expenditure will be in this way traceable to its own class

and sub-division of a class. Every item of expenditure as it arises whether for wages, engine power or material (the three main divisions of expenditure) appears on a voucher that requires acceptance and appropriation at the hands of one or other of the classes and of one of the sub-divisions of a class representing individual responsibility.

Does a system of this kind give the impression that the particular head under which an item is placed is a matter of pure hazard? To make a statement of that sort is as unfair as it is unsubstantiated. It is a matter of regret that when it was decided to ask somebody to report upon British railway practice, the committee in its wisdom did not select an accountant officer of one of the great railway companies, who would have given a report based upon proper knowledge of the conditions. Mr. Acworth is the last man in the world to deliberately mislead people, but although Mr. Acworth is a very clever amateur he is only an amateur, and in matters of detail he is often absolutely and entirely wrong. Mr. Acworth made a reference to hotels. He said that the revenue receipts and expenditure from hotels did not appear under the head of traffic receipts and expenditure, but was entered separately as " Miscellaneous ". That is not the case. These items, or rather the profit derived from the working of the hotel, are entered in the accounts as rent. Then again Mr. Acworth referred to the manner in which merchandise traffic was dealt with. Mr. Acworth says that on English railways the rates for merchandise traffic normally include not merely railway carriage, but collection from the consignor and delivery to the consignee, no separate charge being made for these latter services. That statement is true to a certain extent, but it is very untrue in some respects when analysed. The great bulk of such traffic on English railways is carried at special rates, rates below the classed rates, and almost universally that does not include collection and delivery. Then again in the case of Liverpool traffic it includes collection and delivery at one end, but not at Liverpool. Mr. Acworth made these mistakes because he did not know the actual working conditions.

Then in referring to the committee which had these matters under consideration he stated that of these nine members three were railwaymen, who would make up their minds so that the result in their case was a foregone conclusion. I wish to say that the English railwaymen went into the subject with perfectly open minds, and as a matter of fact every witness coming before the committee was asked to give an illustration of the benefits to be derived from ton mile and passenger mile statistics.

Speaking as a railway man myself, I wish to say that my mind was perfectly open on the subject, and if any man could convince me that benefit would follow the adoption of ton mile or any other form of statistics I should gladly adopt them. This question of ton mile statistics is a purely domestic concern. If American railways find such statistics useful it is not for me to criticise their action, and I believe that my American friends would agree with me that if English railway companies find no useful purpose served by such statistics they will not be disposed to criticise their action.

Meeting held on 6 July, 1910 (afternoon).

MR. COLSON, PRESIDENT, IN THE CHAIR.

The President. (In French.) — We will resume the discussion of subject XIV.

Mr. Sam Fay, Great Central Railway, Great Britain. — Like Sir Chas. Owens I also am one of Mr. Acworth's friends and I must ask him to take anything I may say in that light, but the profound conviction has been forced upon me that the time he has devoted to ton-mile statistics would have been far better employed in the propagation of snakes in Ireland.

The English railwayman has a natural and fundamental objection to ton-mile statistics for the reason that under English conditions they would describe the thing that is not.

In countries where the railways are under the State, and therefore in the hands of a single administration, or upon systems where there is little, if any, of the complications to be found in England, ton-mile statistics show the average charges per ton per mile, and give some idea, at any rate, of the cost per ton per mile on an average (for what such average is worth) of a miscellaneous collection of things whereof the bulk and weight bear no relation the one to the other.

It has been airily stated that the question of division of receipt and cost as between companies, interwoven as they are in England, may be left to the Accountants to adjust, but the infinite variety and the immense volume of merchandise passing over various ownerships in trains belonging to companies other than such ownerships, renders it a matter of impossibility to produce ton-mileage which can in any way be made to represent the charge per ton per mile as paid by the public, or indicate in the remotest degree the cost per ton per mile to the company hauling the traffic or the company owning each particular section of the line.

To illustrate the complexity of the interworking as between English railway companies, more particularly in the principal industrial centres, and where as a consequence the tonnage is heaviest, I will give two examples of the division of the receipts on throughout trains :

Train No. 1 commences its journey at a depôt owned by Company *A* running the train. It then passes on to the line of a dock company, for which a toll of one shilling per wagon is paid. Then on to Company *B*'s line, 1 mile 30 chains in length, with a fixed toll of 3*d*. per ton to the owning company irrespective of the rate per ton for the traffic conveyed; then over 19 miles 43 chains on Company *A*'s own line, the whole of the receipts being of course received. Next for 30 miles 30 chains over Company *C*'s line, one-third ownership of which is held by Company *A*, with engine and guard allowance varying with the price of coal at the pit's mouth. Then over 67 chains of Company *D*'s line with half-ownership to Company *A*, and half the residue after allowing 20 per cent, to Company *C*. Thence over

another piece of Company *C*'s line 10 miles 75 chains long owned in thirds. Next by running powers over Company *E*'s line 29 chains with toll of 0·325 of a penny per ton. Next over 2 miles 16 chains of Company *C*'s line, then over Company *A*'s line for 34 miles 44 chains. Then by running powers over 15 miles 23 chains of Company *F*'s system with an allowance of 40 per cent, and finally, over 4 miles 44 chains of Company *G*'s railway by running powers at 33 $^1/_3$ per cent of the throughout rate. A total of 120 miles 1 chain over eight different ownerships and eight varying methods of division of receipts and expenses. In addition, there is an allowance varying from 0·15 to two-thirds of a penny per wagon per mile credited to Company *A* for use of their vehicles on Company *C*'s line according to distance and class of vehicle.

Train No. 2 commences on Railway *H*, running for 29 chains over its own line, thence by running powers over 37 chains of Company *K*'s line with fixed tolls of 1 $^3/_5$ *d.* per ton, irrespective of the rates for the merchandise conveyed. Then over 60 miles 22 chains of Company *H*'s own line with a bonus of 3 miles out of Company *L*'s proportion of the throughout rate; then by running powers over Company *L*'s line for 30 miles 53 chains, with a working allowance of 33 $^1/_3$ per cent on the throughout charge. A total distance of 91 miles 61 chains, with three ownerships and four different methods of division of receipts and expenses.

It would puzzle the wit of man to make ton mileage figures show any relation whatever between the rates paid by the public and the receipts of either Companies *A* or *H*, or the other lines over which the traffic passes.

I have a case in mind where running powers are exercised over 25 chains of a railway, the owning company receiving a division as for 1 mile on the throughout distance less 25 per cent; over one million tons per annum being thus conveyed over this short distance.

Where traffic in England is the heaviest, interworkings such as these, or of an allied character, are common, and an immense traffic is moved under such conditions.

If these cases were few and far between it might be reasonable to ignore them in the matter of merchandise and mineral traffic; but such is not the case, and in the great centres of industry they are often found to be the rule and not the exception. A portion of the receipts or the expenses, or both, of one piece of line goes to a company which is not the owner.

One company may be instanced where out of 21 million train miles and 24 million engine miles, 6 million train miles and 8 million engine miles respectively represent the running over other companies' lines.

Joint ownership in halves, in thirds, and even in fifths, have to be dealt with; bonus mileages given or received from 60 chains to 20 miles apply to large traffic exchanges. These bonuses, as a rule, are not allied in any way to the charges levied on the public nor to work performed, but are the result of bargains made when the lines were constructed, and are more or less in amount according to the respective bargaining power possessed by the companies at the date they were made.

The same thing may be said of running-

power arrangements; they vary generally from 20 per cent to 40 per cent. These being mainly parliamentary arrangements, represent, in some instances, less than the working and haulage cost; in others, a great deal more than the cost to which the running company is put. The same remark applies to fixed tolls to the company exercising running powers.

The publication of ton mileage figures upon such a basis as this could be of no practical use either for the purpose of comparison between company and company, or as a guide to the charge per ton per mile paid by the trader, or the cost per ton per mile of haulage. The only people who could make use of such figures would be those who are ever ready to beat the "railway dog" with any stick that will come to their hand.

Apart from the fundamental objection to the publication of figures having a basis of untruth, English railwaymen view with disfavour the taking of an average as regards charge and cost of commodities bearing little or no relation the one to the other. Instances might be multiplied almost indefinitely, but one will suffice:

A twelve-ton truck will convey 12 tons of one particular class of merchandise, whilst other common merchandise of great bulk requires twelve trucks to convey the same tonnage. Thus 12 tons in the one case is upon a vehicle with four wheels wearing out the permanent way; in the other, forty-eight wheels are wearing out the same permanent way. Further, the non-paying weight hauled in one case would be about 6 tons and in the other 72 tons, although the revenue tonnage in both cases is identical and ton mileage statistics treat them as of the same value.

Out of this hotch-potch of receipts and expenses divisible between companies without regard to rate charged or work performed, and of units that refuse to unify, English companies are asked to compile ton mileage statistics. Is it to be wondered at that we object and assert that the cost of such a compilation would be sheer waste of hard-earned money?

It is curious that side by side with the extreme advocacy of ton mileage figures in England the professors of railway administration in America — where probably more attention has been paid to statistics than in any other part of the world — are minimising rather than seeking to give enhanced value to ton mileage figures. Thus, Professor Dewsnup, of the University of Illinois, in a recent article on the subject, says:

> There are some happily-dispositioned writers and regulative bodies who see all these difficulties vanishing into thin air when resort is had to some magical pro-rating basis as train mileage or gross ton mileage on the like. These engineers of philosophy are so much in advance of many of us poor mortals that they have no trouble in determining the roadway maintenance expense due to a 50-miles-an-hour 500-ton through express passenger train as compared with that due to a 12-mile-an-hour 2,500 ton freight train, stopping, may be, at almost every siding. Their attitude is picturesque, but unconvincing.

And:

> An arithmetical average is obtained, it is true, but one of treacherous utility, unless environed by a galaxy of interpreting, modifying and saving clauses, only to be used by the initiated, and even then with the greatest circumspection.

And again he says :

> Yet even ton-mileage is unsatisfactory; its general nature necessarily deprives it of efficiency as a measure where conditions are different, as is commonly the case.

And finally, in emphasising the limitation to be attached to statistics as used in America, he says :

> Neither railway officials nor writers employing such statistics have always exercised good judgment in this respect. Too frequently may they be found resorting to reasoning which suggests, as a well known statistician remarked some years age " a man trying to lift himself over a fence by his boot straps."

Turning now to the question of ton mileage as an aid to management and the manipulation of traffic, I believe that there is little, if any, difference, except in name, between the methods employed on the English railways and those of the United States. In the latter country I believe I am correct in saying that for the purposes of movement of traffic, cars are averaged at " per ton," and the gross tonnage of such cars is given as the measure of the engine load for each particular section of line. In England the method usually adopted is to deal with the wagon according to its class — *i. e.*, weight and bulk capacity — either full or empty, as the measure of engine load. Whilst loading is dealt with in America under the name of " tons," in England it is dealt with under the name of " wagons," the average gross tonnage of which is known. The methods, as I have said, are almost identical, the names alone varying.

The mass of information which is at the disposal of English railway managers in the shape of statistics — weekly, monthly or half-yearly — is much on the lines of the information, although in a different form, enumerated by Sir Thomas Rees Price as common in the English colonies.

The English railway managers shy at average as much as possible, and endeavour to get correct facts in the smallest possible compass. They consider that by their methods they get to know more of the actual conditions than by worshipping the god of averages alone.

I have been asked to state that all the representatives of the English railways who are present at this Congress — with one exception — are quite in accord with the remarks made by Sir Charles Owens and with the conclusions which I have just submitted to you. They are convinced in the light of their experience, and having regard to their investigations and the attempts which they have made to adopt ton-mileage, that this system cannot be applied in England

It is to be regretted that there is no report before the Congress of statistics employed by the various English administrations for the sole purpose of internal knowledge and use, as distinguished from the published accounts.

Mr. Hale, American Railway Association. — I trust that the Congress will adopt the conclusions given in the report of Mr. County. They are entirely in line with the facts as stated, and are expressed in such general terms that they can hardly be objected to.

Mr. County shows clearly the advantages of statistics so framed that railroad officers

can use them as a guide in superintending the work of their subordinates, a most important function of statistics.

I had not intended to enter the discussion of ton-mile statistics, but in view of certain statements which have been made I feel obliged to call attention to a point or two.

The gentlemen who object to ton-mile statistics feel that their use will be unfavourable to the proper handling of a varied and high class freight service such as is performed in Great Britain. I can only say that when I had charge of the fast freight service of the Pennsylvania Railroad I found ton mileage statistics of the greatest use. It is not necessary always to use ton mileage figures based upon the average of all freights; they can be worked out for any and every kind of freight, and such figures are frequently of advantage.

Mr. Sam Fay has quoted to us the opinions of Professor Dewsnup, but I hardly think that Professor Dewsnup would claim that he is an exponent of American opinion. He is an Englishman, and has only lived in America a few years. Mr. Dewsnup and I are very good friends. I have, at his invitation, spoken to his classes, but there are certain lines in which he does not represent the views of the practical American railroad man.

There are many cases in America where the trains of one company move over the lines of others in the manner cited by Mr. Fay. For instance, every train of the Baltimore & Ohio Railroad which leaves Chicago runs over the track of four companies. We know, however, the tonnage and the mileage, so there is no difficulty in obtaining ton mileage comparisons with receipts or expenditures.

I must confess that I cannot understand how a railroad manager without ton mileage figures can form a just idea of the performance of his property.

Meeting held 8 July 1910 (morning).

MR. COLSON, PRESIDENT, IN THE CHAIR.

Mr. Jacomb-Hood, London & South Western Railway. — I should like to say that the use made by Mr. Acworth of an illustration I employed when lecturing on the expenditure of railway maintenance, to railway students of the London School of Economics is entirely misleading.

I did, at that time, point out to the students the necessity for the most careful analysis and classification of items of expenditure, if economy was to be secured and explained that, for internal purposes, they must *not* be content with the few comprehensive items, called for by the statutory returns of English railway companies.

I did state that, for practical purposes, I regard these few items as quite insufficient, and that it would be an advantage, and would tend to economy if the careful statistics already compiled

*

by most of the responsible engineers of railways in England were, generally, adopted.

I *repudiate* the suggestion that any English railway engineer does use the five items of expenditure in the statutory form of accounts, as items to which expenditure is charged promiscuously.

As representing a body of men who annually spend large sums of money upon railway maintenance I express the view, in which I believe most railway engineers will agree, that any reasonable means of putting expenditure to the test of analysis and comparison are justifiable, and will tend to secure economy and I state confidently that, for internal purposes, such tests and analyses are already the general practice.

Mr. Patterson, — Far be it from me to contradict a single word of Sir Charles Owens' kind comments on Mr. County's report. On the contrary, as Mr. County's representative, and on my own account, permit me to offer our sincerest thanks for Sir Charles' kindly and eloquent words.

It is, however, only fair to Mr. County to say that he speaks of ton mileage statistics as a *fait accompli* — not as a statistic on trial. As a *fait accompli* he sounds a note of warning as to using them wrongly, or as "the *only* flower in the garden," to quote Sir Charles' simile; but his warning is as to the *use* of the statistic, and not in opposition to its existence, for he believes in it cordially, I am sure.

The value of a statistic is in its *proper* use. It is, perhaps, a bit dull and dry, but nevertheless it may be useful to show *how* statistics of ton mileage may be used and yet avoid the dangers outlined by Mr. County and so ably and kindly summarised by Sir Charles Owens; and so I ask your indulgence, Mr. President and gentlemen, to present on behalf of the Pennsylvania Railroad Company a special case not entirely dissimilar from many cases on other American railways.

The case which we respectfully present is a comparison between ton mileage costs on the New York and Philadelphia Divisions of the Pennsylvania Railroad. These two divisions are very dissimilar. The Philadelphia Division has a predominance of mineral traffic, with long haul. The New York Division has a predominance of merchandise traffic and short hauls. The Philadelphia Division includes the city of Philadelphia, with a terminal delivery traffic conducted by rail deliveries. The New York Division comprises Manhattan Island, with a terminal traffic conducted by water deliveries. The ton mileage statistics showed the *fact* that the costs per ton per mile on the Philadelphia Division were about 3 mills, and on the New York Division 8 mills.

These facts developed a tendency to jump at the conclusion that the trouble was with water deliveries versus rail. But we again used ton mile statistics in much greater detail, separating train costs, lighterage costs, shunting costs and station costs, and found that while all had a bearing, the *station* costs were the principal cause of the grave difference between the two divisions.

Mr. President and gentlemen, I claim that this very instance which I have given you shows that ton mileage properly used gave us a knowledge as to station costs which we would not otherwise have had.

I couple this claim with the most cordial acceptance of Sir Charles Owens and Mr. County's warning that, generally speaking, as well as in the particular instance given, we might (perhaps we often have) used this statistic wrongly — every statistic may be used wrongly as well as rightly. For example, every statistic may be used alone, disjointed from all others, and so deceive. Ton mileage statistics are no exception to this general rule, but *rightly* used I claim they are the brightest rose in the statistical garden, to re-quote Sir Charles Owens' simile.

I ask the indulgence of our learned and kindly French friends to borrow from their lovely and logical language what I may call in my " fierce " American accent " *L'Envoi* " :

1° The comparison of these divisions on the Pennsylvania Railroad showed us our station practice was deficient;

2° It started us thinking about other country' station practice;

3° The Americans are not a modest people yet in this matter of station practice. These comparisons of ton mileage costs have made us more humble, and so we claim for them a virtue in the highest sense;

4° The result of our study of these comparisons of ton mileage costs has turned our minds toward station practice abroad, and especially in London;

5° Our observation of the conditions in London leads us to the impression that the English railway officers are away ahead of us in their station management and we can kneel at their feet as learners.

Mr. President and gentlemen, if I or any of my American confreres here are sent to dear old England, the country of our forebears, to study station practice, and kneel before Sir Charles Owens as learners, may I not hope that Sir Charles will give ton mile statistics the credit for our humble attitude.

Mr. Appleyard. — A desire has been expressed for information about the division of the expenses for passengers and for goods; I very willingly hold myself at the disposition of the members of the section in order to give them all the details I have.

As regards ton-mile statistics, I think that general information is very desirable, but that it is very difficult to obtain as regards details.

In the case of the lines in South Africa and in the other colonies, the comparison of the statistical results with the returns of the other countries and especially with those of the American railways has been very useful and has made it possible to introduce great improvements in the working.

Returns should be drawn up for periods of a certain length, for instance ten or fifteen years.

The returns of the expenses are of particular importance as regards the organization of the line, the staff and especially the amortization which differs widely in the different countries.

Mr. von Strigl, Austrian State Railway. (In German.) — Mr. Chairman and gentlemen, I should like to say a few words about a question which has already been mentioned several times during this discussion and this has also been made the subject of some proposed conclusions.

This is the possibility of comparing the statistics of railways with each other and,

the case arising, of drawing up an international standard for those statistics. I will begin by remarking that Austria has always devoted special attention to the development of railway statistics and that every year a very complete publication appears, which contains, under 1,326 headings, not only the most important results of the operation of the railways, but also a certain number of other useful particulars. Moreover, these statistics deal, on absolutely identical principles, with both State railways and privately-owned railways; not only with main and local lines, but also with minor lines, that is to say, with lines of the most secondary character; finally, also with the industrial connections.

Now, as has already been stated here several times, it is certainly of very great importance that it should be possible to compare this statistical information with that of other countries. Unfortunately, no exact comparison is possible, even on the smallest scale. Similarly the railway statistics of other countries are not as a rule comparable among themselves. It has to be noted that the Austrian government has always as far as possible assisted the efforts made, now for many years, to establish international railway statistics. In this connection I should like to mention an attempt to establish international railway statistics, a description of which was published twenty-five years ago, drawn up and published by Mr. von Brachelli, aulic councillor, of the Austrian ministry of commerce, which then dealt with railway matters.

The question which now arises is whether the present state of affairs, the impossibility of comparing the statistics of different countries with each other, can be modified in the more or less near future. Taking my experience into consideration, I answer this question frankly in the negative. Independently of the diversity of the conditions which affect the statistics in the different countries generally, the classification varies widely, as a rule, in the different countries, as regards the subjects placed under similar headings. Now in all countries the statistical classification, in particular, is closely connected, as regards financial results, with the book-keeping systems adopted in the different countries, and from the moment that, as we have been informed, differences exist inside one and the same country, which cannot be at once made to disappear, it is evident that those differences must be still greater from country to country and that it is hardly possible to eliminate them. In fact every railway will no doubt refuse to rearrange, in a generally radical manner, simply in order to make statistics comparable, the system of book-keeping it is accustomed to, which is specially suited to its conditions and which above all is intended to meet other requirements than those of statistics proper.

The difficulty in the way of any measure of this character is clearly shown by the statistics of the German *Verein*, about which one of the previous speakers expressed the opinion that they might serve as a basis for international railway statistics. However, the determination of the figures for these statistics of the *Verein*, which only includes the German, Austrian, Hungarian, Rumanian and Dutch railways, causes great trouble to many of the railway administrations, although

these statistics include much fewer details than the official railway statistics of other countries; so that very many statistical data have to be included in a given form. Now it is evident that any extension of these statistics, even if the data to be published are reduced in number, should be very ample, if the international railway statistics are to have any value; I mean that from the point of view of the countries included, they should present but few or no appreciable gaps, and that is not possible. I may remark that the difficulties mentioned just now in the way of drawing up the *Verein* statistics have now already led to the adoption of preliminary measures, in the direction of reducing the extent of those statistics materially, probably from 1910 onwards, so that they will be but one quarter of what they were previously.

Now although the reasons which I have just very briefly set forth, make me hold the definite opinion that the conditions necessary for the establishment of international railway statistics at present do not exist, nor will come into existence in the near future, I will, however, not omit to present a proposition which is intended to reconcile the opposing points of view. In fact, although it is probable that the Congress will arrive at the conclusion that the bases necessary for the establishment of international railway statistics at present do not exist and cannot be created, yet it could express the hope that the Permanent Commission should investigate the question whether it would not be advisable to collate and publish certain principal statistical data concerning the railways of the countries represented in the Congress. This information should, in a summary form, include: the length constructed and operated, the capital expended, the stock and mileage of the vehicles, the number of passengers carried, the tonnage of goods carried, the total receipts, the total expenses and, lastly, the final financial results.

It will perhaps be possible later on to supplement, progressively, with other information, these short returns which can be established on a uniform basis and possess a certain value, particularly if they are published as quickly as possible. In any case, one would then start with a basis for international railway statistics, which it is at present unfortunately impossible to draw up, and their compilation will probably be left to a future generation.

The President. (In French.) — Gentlemen, I think it useful to remind you that we have no English shorthand writer present, because the official language of the Congress is French, and speeches should in principle be delivered in French or in the language of the country in which the Congress meets. The notes taken by the secretaries hence only enable us to give a short summary of the speeches made in English. I consequently request the speakers, using languages other than French or German, who desire that their speeches should be reported in full in the *Proceedings* which are published later on, kindly to give copies of their speeches to the bureau.

Mr. Voorhees, Philadelphia & Reading Railway. — A uniform preparation of statistical reports properly prepared and used year by year is of great value to a railway.

The comparison of the results reported as between different railways is of little value and is apt to be misleading to the investor, the law maker and the public in general, unless studies by those intimately acquainted with the characteristics and traffic of the railways whose reports may be compared.

The study of the statistical reports of any given railway will not result in obtaining the actual cost of any operation.

The net returns of the working of the railway as a whole may be obtained.

To determine the actual cost of any element is an impossibility no matter how precise may be the instructions as to the classification of expenses, and however much care may be used in carrying them into execution.

Mr. H. C. Allen, Buenos Ayres Great Southern Railway. — In the evidence which I gave before the Committee referred to by Mr. Acworth I said that although my company had kept ton-mileage and passenger ton-mileage statistics for twenty years, we had found them of practically little or no use, and would discontinue them but for the fact that the information has to be prepared for the Argentine Government annual statistical returns. Twenty years ago, I was, like my friend Mr. Acworth, a statistical enthusiast, or perhaps I should rather say, theorist. Since then the practical application of theory has altered many of my earlier views, and while I think that the present British Board of Trade form of railway accounts leave much to be desired, I agree with my English railway colleagues that their efficiency or inefficiency does not depend on the inclusion or expulsion of ton-mileage statistics. There are, of course, some lines where, owing to the regularity of the classification of the freight and the tare and capacity of the wagons, ton-mileage statistics may be a reliable factor for testing either the earnings or expenditure, but where these vary, as is especially the case in England and is now rapidly becoming the case in Argentina, the ton-mileage averages become misleading and consequently dangerous statistics, except in the hands of statistic experts, well versed in local ruling conditions and thereby able to make their own deductions before arriving at a definite decision. Mr. Sam Fay has shown by quoting examples how difficult, if not impossible, it would be for English railways to get out ton-mile statistics, and even apart from the difficulties of the task there is the question of the cost and the absorption of the energies of the staff in filling up endless forms for the audit or accountant's department, instead of devoting their time and attention to promoting the efficiency of the train services. Some years ago my company kept statistics of the percentage of freight to capacity hauled, but we put an end to that as it was found the staff were devoting all their energy to securing effective statistical results rather than to the earning of dividends or satisfying public requirements. Statistics may be overdone, and at one time they certainly were overdone on the Buenos Ayres Great Southern Railway. I am satisfied that had the Argentine railways never gone in for ton-mileage they would not do so today. Our traffic varies from month to month with the seasons. One month the line is carrying wool, occupying 20 per cent of the wagon

capacity, but earning 54*s.* per ton, while the following month the line would be carrying grain, occupying the full capacity of the wagons, but only earning 6*s.* per ton. With such varying classifications, what possible use can be made of ton-mileage averages? Again, taking the so-called gross ton-mileage which the Argentine Government insisted on, that is merely the total tare of the wagons divided by the axles, and a unit of two axles per wagon was adopted for all statistical progress, and this, multiplied by the total vehicle-miles run plus total ton-mileage, gives the so-called gross ton-mileage. As, however, the railways have in service all classes of wagons, from an 8-ton with 10-ton tare to a 45-ton with 15-ton tare, what reliability can be placed on the average gross ton-mile? Efficiency in operation can only be obtained by every traffic employee intelligently watching and recording every train coming under his notice and reporting promptly where there is any evidence of careless loading or extravagance in hauling power. It was hoped that by carefully recording gross ton-mile statistics it would have been possible to appropriate the cost as between passengers and goods, but after many experiments it was agreed that, although statistics showed it cost $2\,^1/_2$ times as much to carry a passenger ton one mile as a ton of goods, this was disproved by subsequent experience. It is all a case of averages, pleasing, possibly, to the theorist, but useless and misleading to the practical railwayman.

Mr. Plant, Southern Railway, United States. — Recognizing as we do the value of and the substantial benefits to be derived from proper and accurate statistics, the papers read and the discussions on this subject are very interesting to the delegates from the United States.

Competition and an upward tendency in the cost of both labour and materials, with no corresponding increase in the rates charged for transportation, make it necessary for us to watch most carefully operating costs. This supervision can be given only through the medium of proper and reliable statistics drawn to show both the traffic produced and the costs to transport it.

Railway statistics in the United States may be divided into two classes; *i. e.* :

1° Statistics reported by the directors to the shareholders and those required by the State and Federal Governments;

2° Statistics prepared for the managing officer, which are used by him in determining the efficiency of operations and of individual operating officers.

Those referred to in the first class are prepared and reported annually, along fairly uniform lines, and they are general in their character.

Those of the second class are prepared in much greater detail and are reported daily, weekly and monthly along lines best suited to meet the requirements and the physical and traffic conditions of the individual railway.

On many railways, statistics are prepared to show not only the results of the entire line, but also those of each operating division or section, of the individual operating officer, the train, the locomotive, and on some lines the individual engine driver and the fireman.

In discussing this subject I shall, as far as practicable, confine my remarks to

those statistics referred to in the second class which are prepared and used on the lines which I represent.

In the first place, I desire to talk about the method which we use, not only in producing statistics, but in the general audit of our revenues, especially revenues derived from freight traffic.

Way-bills or manifests upon which freights move are forwarded daily by the agents at receiving stations to the audit office. Upon receipt in the audit office all data necessary to the audit and for statistical purposes are transferred by means of punch marks or holes to a card. Thus we have a card representing each way-bill and carrying all information required. After preparing the cards in the manner described — which is done at the rate of from 250 to 300 cards per clerk per hour — the remainder of the work — both the audit and the statistical work — is done mechanically through the medium of electrical sorting and tabulating machines.

The element of error is reduced to a minimum and the errors are confined to the punching of the cards. The average record is less than two errors per one thousand cards. The errors, however, are detected and reflected by the tabulator in the audit, so when we come to the preparation of statistics the cards are practically free from errors.

To determine the volume of any particular class of traffic moved between a pair of stations, all the cards from and to those stations are placed in the sorter, which is set for the particular class desired. Electricity is applied, and the cards for the class of traffic desired are separated from those of other classes at the rate of, say, sixty per minute. The cards are then placed in the tabulator, and the tonnage and the revenue are determined electrically and with perfect accuracy.

Practically all freight revenue accounting and the statistical data, including the division of revenue, tons and ton-miles between states, operating divisions and individual lines, and also between State and Interstate traffic, are produced through the medium of the tabulator. Classified tonnage statements from individual stations showing revenue, tons and ton-miles are also produced with the tabulators.

Thus accounting costs, as well as the time requisite to the production, are reduced to a minimum.

There are three important elements in operations in which statistics are not only useful, but very essential to economical operations.

They are :

1° The solicitation and equalization of traffic;

2° Transportation costs to receive, transport and discharge traffic;

3° Locomotive and train load.

It is very necessary for the chief traffic officer to know the results accomplished by his field officers, particularly with respect to the volume of competitive traffic secured. It is also of great importance to him to know whether or not his line is receiving the longest possible haul on traffic originating on his line destined to points on other lines, and on traffic moving in the reverse direction. It is likewise important for him to know the volume of competitive traffic received from and delivered to each connecting line at individual junction points. The equalization of

tonnage in both directions over an individual line or section, to the end that empty one-way hauls may be avoided, is a very important matter. All this information can and should be shown by statistics.

Numerous units are produced for gauging transportation costs, prominent among which are: locomotive, train and car miles shown separately as between passenger, freight and mixed, whether light, helping, loaded or empty, and the direction in which moved; individual gross transportation costs and costs per locomotive mile for enginemen, fuel, lubrication and other locomotive expenses; costs per train-mile for trainmen and for other train expenses, and for yardmen or shunting service; pounds of coal consumed per locomotive and per ton-mile and station service per one dollar of revenue earned. The locomotive and train load is a most important factor to be reckoned with.

Operating costs may be reduced to a minimum and the economical results thus accomplished are destroyed unless the maximum freight-train load is secured at the start and maintained throughout the journey of the train. The hauling capacity of locomotives is known. Each locomotive is rated and efforts are made to load them to their maximum capacity. The tonnage of each car is determined from the weight of the traffic shown on the way-bills or manifests which accompany it. To this weight is added the tare weight of the car, and in this manner the actual gross weight of the car with its load is determined, and the weight thus produced is used as a base for loading locomotives.

Through this medium each division superintendent is advised daily of the train tonnage on his division. The general manager is advised of such results, together with the results showing ton-miles per train and per locomotive and costs for enginemen, fuel, trainmen and other locomotive and train costs per ton-mile, through the medium of statistics prepared in the general office.

Much has been written about the railway statistics of the United States, and I regret to say that possibly some of our English and Continental friends have been confused by some of the articles sent abroad. Some writers tell us it is possible to determine the total operating costs to move one ton of freight one mile or to transport a passenger one mile. We can approximate such costs, but we cannot and I doubt whether we shall ever be able to determine them accurately. But few of the American railway accounting officers attempt to make the separation, and when made, the results are used for comparative purposes only.

About fifty to sixty per cent of total operating costs can be accurately assigned to the two classes of service; the remaining costs must be arbitrarily assigned.

Prior to 1 July 1907, there was a diversity of accounting methods and practices on American railways. While generally speaking the principles were the same, the methods were not, and it was difficult to satisfactorily compare operating results, one line with another.

Simultaneously with the passage of the Act in 1906 vesting in the Interstate Commerce Commission the power to prescribe the accounts to be kept by railways subject to the Act, a committee consisting of

twenty-five chief accounting officers of railways in the United States was appointed by the Association of American railway accounting officers for the purpose of aiding the commission, through its representatives, in unifying and modernizing our railway accounting methods.

This work has been under way for nearly four years, and is about completed.

We now have uniformity in classifications of revenue, operating expenses, locomotive, train and car mileage, additions and betterments, and construction expenditures and also in the form of the general balance sheet.

Just emerging as we are from a four years' siege of accounting changes and reformations, the railways of the United States would, I daresay, hesitate to approve the suggestion made by my German friend for a form of international statistics. The thought is a pretty one, an interesting one to contemplate, but we of America feel that we should sit still for a while and catch our breath.

We should be glad to know what our Continental neighbours are doing, and should be pleased to show them what we have in the way of statistics; but, as I view it, there are many reasons why an international method or plan of statistics would be impracticable.

Statistics, to be of value and to be used effectively, must be available promptly after the performance of the service for which they are prepared. They should be accurate and in my judgment drawn to meet the requirements of the individual line They should deal only with those costs or factors incurred and created directly by the operating officer under review. The introduction of averages, estimates and irrelevant elements, in my judgment, destroys the real value of the statistics.

Mr. Mahl, Union Pacific Railroad. — I thank my English friends for their communications relating to the question of statistics. If the American railways tabulate very minutely all relating to passenger-mileage and to ton-mileage, it is because they wish to have this information as units for the intelligent operation of their lines.

The American companies are transport undertakings which above all try to augment the number of passengers carried and the tonnage of the goods. They also wish to be able to compare accurately what these transports bring in and what they cost, in order, on the one hand, to increase the receipts, and, on the other, to reduce the expenses.

The chief result they aim at is the development of the traffic and they also strive to give the public a good service. The companies also try to equalize as much as possible the traffic between their different lines and do their utmost to have the trains as fully loaded as possible.

The accurate data supplied by the passenger-mile and ton-mile statistics have enormously contributed to the progress of the American railways, which have increased since 1860 from 30,000 miles to 270,000 miles.

In conclusion, I thank my French, English and German colleagues for the information they have kindly supplied.

Mr. Rathgeb, Swiss Federal department of posts and railways. (In German.) — The International Railway Congress, which occupies itself with useful investigations

of all kinds, has also extended its researches to the method of compiling railway researches and statistics. Statistics are certainly an interesting field. This is proved to us by the fact that they have been existing since there have been railways, that they have for a long time been among the agenda of the Congress and that many delegates from all countries and railways have come to take part in the Berne session.

We other Swiss have been looking forward to this session with pleasure. In our small country, much importance is attached to accurate statistical information. Railway statistics are especially complicated, owing to the large number of railway enterprises and of systems of traction. If some day the monorail is added to the latter, the task of the statistician will become even more arduous.

Should the Congress investigate whether it is better to compile statistics at once, or annuals returns? We think that both systems can render excellent services. The practical and experienced official, who wants to keep acquainted with the importance and the progress of the service, will easily find the material for daily, weekly or monthly returns, of the carriage of passengers and goods, the number of trains and the journeys of vehicles. Those are accordingly points which it is superfluous to discuss at length.

The question which seems to us of much greater importance, is that of the annual statistics. We would like to ascertain, at the end of a sufficiently long period, whether there has been any forward or any retrograde movement, and whether there have been any changes in certain services. This information is of interest to the managing officials, as well as to the capitalists and to the higher authorities.

In order to make a complete comparison, we also consider the results of neighbouring enterprises and the railways in other countries. As regards the latter, our interests blend. It is no doubt for that reason also that it was desired to bring before the Congress the subject of uniform statistics and that the Congress has already adopted a resolution stating that it was desirable to unify the book-keeping of receipts and expenses.

The realization of this resolution, which was adopted in 1905 at Washington, would form a first solid foundation for a universal movement in favour of the unification of railway statistics. We have today learnt how the differents unions, for instance the European railways, try to unify their systems of book-keeping. On the other hand, the interesting reports submitted by the reporters show that in America also a common basis is sought for. We have, moreover, learnt, with much pleasure, from South African delegates that the normal principles of statistics have now been unified there and are clearly determined by the different railways. We thus see that there are movements in favour of uniformity, in all the countries, in all parts of the world.

We might also mention that the International Light Railway Union, which is an association of tramways and of narrow-gauge railways, is ahead as compared with main railroads. Years ago already the "light railways" have laid down a standard programme of receipts and expenses, which has been adopted as an obligatory standard by a large number of enterprises of this kind.

The need for comparison is also felt by other administrations, such as those of posts and telegraphs. The central offices organized at Berne publish every year very detailed statistics of the results obtained in the different countries.

We in Switzerland expect happy results to follow this session. We have now for quite a long time been intending to make alterations in our system of book-keeping, which dates back to twenty-five years ago. Electric traction, which has recently come to the front, makes it necessary, from many points of view, to modify the classification. There are lines with mixed traction: steam traction and electric traction. Electric trains are generally of another kind and of another type as compared with those on steam lines. The staff and the rolling stock have had new classes added. It is necessary that the statistics should allow for and deal with those new conditions by a corresponding extension of their scope. We hope to find at this session of the Railway Congress new information and bases utilizable for a future system, universally applicable, of book-keeping and of statistics. Now it seems, in spite of the very comprehensive reports and the long discussions, that the question submitted to the meeting is not yet sufficiently elucidated and that one cannot record any practical agreement as to this question. Differences will exist between one country to another. Under these conditions, it will be difficult for us to come to any decision. We do not know whether we are to uphold the regulations in force on the German railways, or to support the French standards, or whether it would be preferable to adopt the new American classification, or the simpler English system. But perhaps we should do better if we improved our existing methods and try and deduce standards from them.

Gentlemen, the difficulties of unifying statistical bases are well known, and we cannot make them disappear from today or tomorrow. These are caused by the national laws, by the railway regulations, by traditions, by opposition on the part of the directing authorities, and by many other causes. In certain circles there is perhaps also some antipathy or apathy as regards statistics, which hinders the solution of the question. This new auxiliary science often presents itself with a voluminous, proud and exaggerated appearance, and sometimes involves an amount of work and expenditure which is not justified by the result.

In order to arrive at any result, it would in every way be advisable in the first place to establish certain simple and fundamental facts, as has been well said by Mr. von Strigl, delegate of the Austrian State Railway. We must not for the moment enter too much into detail, nor must we examine whether the results of working are to be determined and compared on the basis of the ton-kilometre or train-kilometre or any other unit. It would be advisable, in the first place, to come to an agreement about the fundamental principles, that is to say, about the uniform classification of the working expenses. In order to determine or compare the working expenses either as a whole or in units and services, they must, to begin with, be classified according to the same principles. Consequently, it must not happen that the expenditure on the locomotive staff and on the coal consumed should be placed under one head

by one administration, and under another by another administration.

The possibility of unification seems to exist, because every normal railway, whatever country it may be in, has characteristics in common with the other railways. We find everywhere fixed installations which have to be maintained in good and safe condition, a rolling stock which must be driven and conducted, a service for dispatching transportation, a general administration which directs the whole work and considers matters of finance. It is certain that sooner or later one will come to an agreement as to a common system of statistics for these principal services and that gradually other sets of statistics will receive the same form. But in order to arrive at this unification, we must try to conquer existing obstacles. Many prejudices will have to disappear. There must be a certain spirit of conciliation between the nations. The delegates of the different nations and parts of the world must join hands; an admirable example of this is exhibited by the international postal monument at Berne. In order that the Congress may really arrive at useful results, it is hence necessary that the resolutions passed at the sessions should not be purely negative conclusions or only express simple wishes. This great meeting of railway delegates must not be contented with declaring that there are many difficulties opposing the unification of the bases of book-keeping and of statistics; it must on the contrary make a strong and logical effort to overcome these obstacles.

The President. (In French.) — Three other members have given in their names as wishing to speak, not including Mr. Acworth who no doubt will desire to answer some of the remarks which have been made about his report.

I therefore propose to you to adjourn the meeting and to continue the discussion this afternoon. (*Approval.*)

Meeting held on 8 July 1910 (afternoon).

MR. COLSON, PRESIDENT, IN THE CHAIR.

Mr. Hyde, Great Eastern Railway, Great Britain. — I desire to associate myself with the remarks of Sir Charles Owens and Mr. Fay with which I entirely agree and wish to supplement them with e few particulars.

I think it will be admitted that the only value of statistics lies in their accuracy and that any treatise thereon should possess the same qualification.

It is therefore to be regretted that Mr. Acworth did not obtain the assistance of a practical railwayman before publishing his report in order to avoid the inaccuracies which have crept in.

For instance in discussing the proposed form of accounts as recommended by the committee appointed by the Board of Trade he states (p. 91) (1) that railway

(1) Vide also *Bulletin of the Railway Congress*, number of January, 1910, p. 7.

expenses of locomotives have for the first time been definitely separated from maintenance expenses!

I may remind him that the locomotive running expenses are separated from the maintenance expenses in the present form of accounts and have been so separated for the last forty years.

Page 92 of the report informs us that the present practice of the railway companies is to charge the cost of collection and delivery of all traffic whether by goods train or by passenger train against the goods traffic receipts.

This is inaccurate, as the railway companies properly discriminate between the two heads of expenditure and apportion them accordingly.

I would also call your attention to page 90 wherein in discussing the new form of accounts the following appears :

> The total receipts of all the various branches of the business, railway, steamboats, canals, docks, etc., are brought together, the total net income is established and the proposed appropriation thereof to the payments of interest, to dividend and to reserve funds set out in logical order.

One naturally concludes that this is one of the improvements brought about by the committee, but in point of fact this is merely the continuance of the principle which already exists in the railway accounts *viz.* in the revenue account the net revenue account and the proposed appropriation of the balance.

As regards the question of ton-mile statistics, and passenger-mile statistics, it is obvious that when applied to all railway companies without due allowance for the varying conditions, any comparison must be valueless and not only valueless but dangerous and misleading.

Not only are the circumstances of different countries dissimilar but different railways within the British Isles are subject to different conditions and further there are also differences between the different districts of a single railway company.

On the Great Eastern Railway for example, the greater part of the system runs through an agricultural district sparsely populated and with a light traffic as a result, whereas in that section which lies nearest to London, the traffic is dense, the two sets of conditions being of an entirely opposite nature.

Again in comparing one railway with another, let us take two examples.

Railway *A* is mainly concerned with heavy mineral traffic worked over easy gradients whereas railway *B* has no minerals at all but only a light agricultural traffic and difficult gradients over which to work it.

Again, as regards passenger traffic, railway *A* in a busy manufacturing district has a good "town to town" traffic distributed fairly evenly over the whole day, whereas railway *B* has a traffic very heavy at certain times of the day, and slack at others.

The conditions therefore are out of all comparison and to apply one rule to them all merely results in conclusions which are misleading.

Further Mr. Acworth himself has said that 80 per cent of the heavy traffic varies on different railways.

What is really essential is that the executive officers should be in possession of detailed statistics as regards the movement of the traffic and that these statistics

should be in their hands as soon as the traffic passes.

This is the practice which prevails at the present time and no quantity of ton-mile figures could effectively replace them.

The President. (In French.) — Several members have asked me to request the speakers to be as brief as possible, in the hope of finishing the discussion of this subject today. As we still have to hear the reporter, who wishes to reply to the numerous remarks which have been made, it is advisable not to be too long and to avoid repetitions.

Mr. Aslett, Furness Railway, Great Britain. — I am of opinion that certain alterations should be effected in the British railway statistics. The reform bill will no doubt go through and it will thus be possible to introduce the desired changes in so far as it concerns the question before us, more especially the question of passenger-miles and ton-miles.

The companies endeavour first of all to ascertain whether the transports pay or do not pay. There is a great difference in the transport of heavy goods, coal, coke, iron and steel. The companies receive the particulars as to weight, and when there are special trains, particulars are also supplied concerning the loading of these trains. The British companies can obtain this information without a great deal of expense or difficulty.

I am of opinion that it would be useless to multiply and complete the statistics, considering that this entails a loss of time and that it is better that the officials should be able to give all their time and all their attention to the railway service proper.

As regards the accounts, every month I hand over to my Board a complete extract of the distances covered by the engines, and a statement of the receipts and expenses, and this information enables them to establish the comparison between the results obtained every year with those of the previous years and months.

To conclude, I am of opinion that it is not desirable to overweigh the executive bodies with too many statistical details.

Colonel Bonham Carter, Madras & Southern Mahratta Railway. — I feel that an apology is due from a comparatively unknown man for taking up the time of the conference. My excuse is that in India we have had for nearly sixty years uniform principles of accounting, for nearly forty years uniform accounts and for the same period a mass of published statistics based on every conceivable unit, train-mile, ton-mile passenger mile and gross ton-mile, a part of which will be found reproduced on pages 53 to 56 of Sir Thomas Rees Prices' report (1).

With regard to my personal qualifications I was three and a half years under-secretary for railway traffic and statistics to the government of India and subsequently for seven years the general manager of a system of 1,600 miles.

It appears to me that three of the reports dealing with statistics from the point of view of the Congress hardly distinguish sufficiently between operating accounts, returns, or temporary statistics, and what I would term administrative or permanent statistics and of the objects of these distinct entities.

(1) Vide also *Bulletin of the Railway Congress*, number of December, 1909, pp. 1619 to 1622.

The accounts with the reports based upon them are required to give the shareholders or owners of the railway a statement of its operations as a dividend-earning concern. We should I think all agree that they should be based on sound financial principles and while the reports will give such explanations as are necessary to throw better light upon them, as mentioned by Mr. Hyde, I do not, for reasons which will be mentioned, attach so much value as some to comparisons between different railways while considering that so far as circumstances allow uniformity is desirable.

The operating returns or temporary statistics are and must be rendered daily, weekly or at other short intervals to the officials responsible for working the line, on I should imagine every railway in the world, to enable them to watch the development of traffic and apply remedies to defects in working.

It is the extent to which these operating statistics must be compiled into a more permanent form to give the superior operating officers including general managers the necessary information as to the progress of their business and how far other more permanent administrative statistics must be maintained for comparative purposes over a series of years which is the crux of the whole question. But is not this a question of circumstances? The value of all statistics we are told by our reporters depends on their utility and on the man behind them and on his full knowledge of all the circumstances affecting them.

On a line of such size that the general manager and his assistants can keep in touch with the business and when the administration are close at hand, so that personal explanations are possible, fewer statistics are required than if the general manager has his Board of Directors at a distance as in India or Argentina or manages, as in other countries, so large a system that the president or general manager is bound to base his control to a greater extent on the information furnished to them by statistics.

May I recall to the section a similar discussion on the subject of high capacity wagons at Paris in 1900 and of the resolution recorded upon it? As bearing on the value of statistics as a basis of comparison of the working of different railways, I may mention that the government of India with the aid of the voluminous statistics which are published in that country used for many years to compare the working of each of fourteen railways with its own working for five previous corresponding half years and with the working of two other railways selected as far as possible for their similarity to itself.

It was my duty for three and a half years to make these comparisons. It gradually dawned upon the Government of India that the results obtained were simply the confirmation of the accounts and reports on which the statistics were based and the comparisons were discontinued.

When I became a general manager I found that the system under my control was such that I required an abstract for the different sections of the line of certain operative statistics. I did not find the Government statistics based on passenger and ton miles of any practical use to me. Any information which they contained I

obtained from my operative statistics at a much earlier date and in many cases I found both ton mile and passenger mile statistics misleading.

I will mention one of them.

On a length of line of about 500 miles on which the tonnage hauled was about 700,000 tons and the ton-mileage 100 million ton miles half yearly, the rates in force for coal were something under 0·2 pence per ton mile.

These were low rates, but although the maximum load of an engine was 500 tons of freight and the wagons had to return empty the whole way we were satisfied that they would give us some profit. Owing, however, to sea competition they were not made use of by the public. Suddenly one of our customers decided to carry thin coal by rail instead of by sea and we obtained 40,000 tons or 20 million freight ton miles of this traffic in one half year.

But the effect on the statistics was first to largely increase the proportion of working expenses chargeable against goods traffic which is divided in the proportion of gross ton-mileage, to reduce the average sum received for carrying a ton one mile and to increase the average cost of so doing and reduce the average profit.

This one occurrence thus vitiated the whole of a large group of statistics and showed a loss instead of a profit.

I am desired to add by another Indian general manager present that he shares my views as do many others of the inutility these elaborate statistics prepared for Government purposes. I may say that judged by these statistics (he carries large quantities of jute which loads lightly), his average load is something shocking and his train loads poor compared to those of his neighbour, a grain and coal carrying line. But he rubs along somehow and his line pays 9 to 10 per cent.

Mr. Evelyn Cecil, *vice-president*. — The discussion to which we have just listened would have had a better result if Mr. Acworth had not concluded his remarks in the terms which you have heard. I maintain that it is impossible to say that there are no principles of railway statistics in the United Kingdom.

English companies, like American companies, consider that railway undertakings are a business, and that they should be run like a business.

The object of statistics appears to have been lost sight of. The aim is not to give mere mathematical formulæ; statistics should be used as a sort of pulse to watch the progress of the line.

Mr. County, in his report, put three points which seem to me necessary to impress; *viz.*, the need for obtaining statistical information quickly; the need for clear statistics; and desirability of separating direct from indirect expenses, so as to secure complete results. In short, rapidity, clearness and precision.

Mr. Rathgeb called attention this morning to the great difficulties of unifying statistical results, and Mr. Hyde said that a comparison of them had not, from a general point of view, a great interest for the public. Statistics so complicated are often misleading.

I propose the following resolution :

" Subject to the particular conditions affecting railroad accounting resulting from control of, or financial interest in the railways by the State.

" The Congress finds :

" 1° That statistics, to be of value for operating purposes, should be made available to the operating officers at the earliest practicable date after the performances of the services for a given period;

" 2° To be of the greatest value from an economical operating standpoint, statistics prepared for operating officers should include only such costs as are directly incurred by the officer interested, and all indirect costs should be separated therefrom;

" 3° No one line of statistics should be exclusively relied upon, but statistics reflecting all factors essential to the working of each particular railway, both as to revenue and costs, should be prepared and properly considered;

" 4° That the respective statistics of railway administrations are based on principles suitable to their varying conditions, but that the circumstances and conditions of working necessarely differ in different countries, and that it is practically impossible to arrive at an absolutely uniform system of operating statistics applicable alike to all countries."

The conclusions which I have just read represent the opinion of the British railway companies, and have equally the assent of the American companies.

Mr. Acworth, *reporter*. (In French.) — As a commencement, Mr. President, I should like to apologize in the official language of the Congress for having been responsible for the fact that so much of the time of an International Congress has been occupied by the discussion in English of a question of purely English interest. I seem quite unintentionally to have raised a storm. For two days the storm has raged and after all it is really only a storm in a teacup.

Continuing in English he said :

I will endeavour very briefly to reply to the principal charges that have been made against me. In the first place, I decline to be responsible for what I have not said. I did not say there were no railway statistics in England. Everybody knows that there are, and that the Board of Trade publishes them year by year. What I did say was, " there are no *principles* of statistics". I continue to be of that opinion, and I am confirmed in it by the fact that not one of my critics has so much as attempted to indicate what these principles, if they exist, are.

I repeat that my report is purely personal, and the expression of my individual opinion; but Mr. Evelyn Cecil uses a misleading expression in saying that the Board of Trade has not accepted it. It has not accepted it because it has not been asked to do so. It would be equally true to say that the Board of Trade has not accepted the Ten Commandments.

Sir Charles Owens and other speakers have said that I represent nobody, that I am an amateur. An amateur in the ordinary acceptation of the phrase is a person who devotes himself to a subject for love of the subject itself without hope of personal gain. I do not know whether Sir Charles Owens intended to pay me a compliment, but I certainly accept it as such.

Mr. Jacomb-Hood complains that I have misrepresented him. The words in my paper are as follows :

The chief engineer of one of our great railways a few years ago described these four sub-heads as four paper baskets, which stood by the side of the table of the engineer of each

railway company. It was, he said, a matter of pure accident into which of the four baskets any particular item of expenditure happened to be thrown.

The precise words of Mr. Jacomb-Hood are these :

> A system that provides four vast heads of expenditure, like four big dirty linen baskets, into which all this expenditure as it arrives can be thrown, without much examination or classification, surely stands self-condemned, and calls for the attention of the coming race of railway accounting officers.

I owe Mr. Jacomb-Hood an apology for an inaccurate quotation : I wrote " paper baskets," I ought to have written " dirty linen baskets".

I am accused of being a theorist because I ask for statistics which have no direct bearing on actual operation. But I have never said that statistics by themselves were a remedy. What I have said is that they disclose facts and enable the appropriate remedy to be applied. Let me give a parallel. Nobody supposes that the publication of the comparative mortality in different towns in itself reduces the death rate. But if the figures show that in a given town the mortality from, say, phthisis, is far above the average, they force the health authority of that town to pay attention to the fact, and to set to work to modify the conditions responsible for the unusual death rate.

I have been blamed because I have said nothing as to statistics compiled by the companies but not published, and because I have taken no steps to enquire what these statistics are. My answer is that I regarded published and official statistics as alone coming within the scope of the paper, and there was, therefore, no reason for making any further and private enquiry.

Sir Charles Owens admits the utility of international comparisons, but under present conditions it is impossible to compare England with any other country owing to the gaps in our statistics. Let me give one instance. It is commonly supposed outside England that the English passenger rates are among the highest in the world. The only figure available to outside critics is the ordinary third class rate of 1*d.* per mile. I have often myself had occasion to point out that this ordinary fare is very far from representing the actual sum charged by the English railways for carrying a passenger one mile. I have told foreign critics that in my belief, based on such scanty statistics as are available, the average passenger mile rate in England is hardly more than $^1/_2$ *d.* And I have found, not unnaturally, that foreign railwaymen refuse to accept my conjectural figure as fairly comparable with the official statistics of the average passenger mile rate of other countries.

Mr. Hyde says that comparisons based on ton-mileage are misleading. But comparisons based on tonnage alone are even more misleading. For instance, the Taff Vale Railway and the Midland both carry coal in millions of tons. The Taff Vale has an average haul of say 15 miles; the Midland an average haul which can hardly be less than 50 miles. Surely a comparison between these two companies that ignores the element of distance is at any rate not less but more misleading than would be a comparison which allowed for it. Of course, all statistical comparisons are liable to mislead those who use the

figures unintelligently or unfairly; but when my critics, for example, object to ton-mile comparisons because they lump together ton miles of feathers and ton-miles of coal, they seem to forget that the source of error in this case is in the tons and not in the miles. Now the tons they do give at present, and I have not heard any suggestion that this figure at least should be suppressed.

I am told on the authority of professor Dewsnup that the Americans recognise that ton mile figures are useless, but, apparently, all that the professor has said is that they are not an infallible guide. Nobody that I know of ever said they were, and the fact remains that the American railwaymen, in common with the railwaymen of practically every other country in the world, except England, recognise the utility of ton mile figures as on the whole the best single unit of comparison. Where Englishmen, in default of better information, make comparisons of receipts or expenses per ton, and compare tons per mile of road, Americans compare receipts or expenses per ton mile, and compare ton miles per mile of road.

I am told that ton-mile statistics are impossible in England in consequence of the tangled relations between English companies. But the same conditions, as Mr. Hale and others have shown, exist in other countries and are successfully surmounted. In fact, the minority report of the Board of Trade has laid down precise rules for surmounting them, and no one, as far as I am aware, has ventured to assert, specifically and in detail, that they are either insufficient for their purpose, or incapable of practical application.

The result of our long discussion is, I venture to say, to show that in the opinion of the practical men of the civilised world ton-mile statistics are everywhere practicable and everywhere useful, " England excepted," say the English railwaymen. But at this very moment they are used in practice and found useful in England itself. I am told that thirty years ago, in the infancy of the science of railway management, a general manager of a great English system declared ton-mile statistics to be useless. I reply that, in this present year, the general manager of a great English system, after ten years' experience, finds ton-mile statistics of great practical utility. But enough of a question purely English. I apologise to the section for detaining them so long.

One word in conclusion as to the resolutions proposed for adoption by Mr. Evelyn Cecil. I am perfectly ready to vote for them. For they assert that the statistics of every railway system ought to contain every element both of operating receipts and of operating expenses, and this, as it seems to me, necessarily implies ton miles figures, for I do not think that a railwayman of any nationality will stand up and assert that length of haul is not an element both of the quantum of receipts and of the cost of operation.

The President. (In French.) — I have received from Mr. von Strigl a request for the closure of the discussion. If this proposition is adopted by the meeting, I will read out the proposed resolutions which I have before me and the meeting will then have to decide whether it will at once proceed to the vote or whether it will prefer to wait till the proposed resolutions have been printed.

Mr. Timonoff. (In French.) — I am of opinion that the proposition should be adopted but with the reservation that the speakers who gave in their names before this proposition was brought forward, should still have the right of addressing the meeting. (*Signs of approval.*)

The President. (In French.) — I put Mr. von Strigl's proposed closure, subject to the reservation just mentioned, to the vote.

— The proposition is adopted.

Colonel Haines, United States government. — I desire first to state that I do not speak in the name of the government of the United States, nor am I authorized to commit that government to the resolutions which have been reported to this section. Nevertheless, I appreciate the opportunity afforded me to take part in their discussion.

It is a fundamental principle that statistics should be prepared with a view to the purposes for which they are intended. The immediate purpose in this case is to draw upon experience for information to be applied to future operations. Statistics of this character must necessarily be compiled by each railway administration from its own experience, in connection especially with the operations in the several departments of maintenance of way and structures, of maintenance of rolling stock, of train service and of traffic returns.

In these several departments, different units of comparison are used. As to cost of service, there are employed the train-mile, the locomotive-mile, the car-mile : as to traffic returns, there are applied the ton-mile and the passenger-mile. But these statistical units are not capable of comparison with each other. For this purpose there is required some generally accepted unit which may replace or harmonize these several distinct units. Since they are not interchangeable they require some common denominator to which they may serve as coefficients. This conclusion is even of broader application when statistics are to be applied to a comparison of the operations of separate administrations under differing conditions; conditions also varying from year to year and which, in many respects, are quite unlike when a comparison is to be made between railways operated by steam or by electricity.

To my mind, there is but one unit of comparison which can be applied to railway operations under such varied conditions; and that is, the foot-pound unit exerted at the locomotive draw-bar, as determined by the dynamometer. By such tests, there may be definitely ascertained the tractive power exerted in the performance of any train service; and the cost of that service, whether in freight or passenger traffic, may be as definitely determined. From such statistics a basis can be established which will be available for comparison of any railway operations, however varied may be the conditions and circumstances under which they are performed.

Nor should statistics of this character be confused with statements of earnings and expenses, of assets and liabilities. These are matters of book-keeping which are capable of being stated clearly and accurately; for they are based upon records of monetary transactions which

must necessarily balance. In this respect they are to be distinguished from the records of physical facts, and when statistics are to be applied to the comparison of railway operations, the cost of the service as established by the balance sheets must be correlated with the physical facts represented by statistics on some practical basis. This can only be secured by the adoption of a unit of comparison which is capable of uniform application under any circumstances or conditions.

Another matter to which I would refer is the fallacy of the application of averages to special cases. An average is only the mean of the facts under consideration. It is an abstraction, which is rarely of value for practical purposes, as it can only be utilized with advantage for such purposes in operations conducted under identical conditions. For the same reason, averages should be employed with caution when the results of railway administration are to be judged by statistics. If the reputation of a railway management is to be affected by such comparison, it is but a matter of justice that the statistics used for this purpose should be free of any imputation of defect in their composition or of unsuitability for the purpose for which they are intended. This is the purpose for which averages are utilized in the regulation of railway operations by external authority, and it does not seem to me that the propositions contained in the resolutions, as reported, fulfil these conditions; at least to such an extent as would justify their adoption as an international measure.

Furthermore, the character of the official statistics which should be required from railway administrations by a State government is still the subject of investigation in the United States, and with especial reference to the purpose of comparison between them. If the delegates from the United States could present to this section such statistical formulas as have been suggested by Mr. Acworth they would be pleased to do so, but it is impossible, for the reason that this is with them, at the present time, a desideratum yet to be attained.

In conclusion, I would beg of you not to support the resolutions as reported, and not to compromise yourselves by the recommendation of measures which cannot be realized.

Mr. Brandt, Russian State Railway. (In German.) — Since a statistics office exists in Russia, that is since 1873, statistics have been kept of ton-kilometres or of pood-versts, as used in Russia. The tonnage relating to the different railways must be reduced 47 to 49 per cent because in the total there is a certain number of tons counted several times over owing to transfer from the lines of one company to the lines of another company.

The President. (In French.) — There are no more names down for speaking. Does the section wish the different resolutions proposed to be put to the vote, or does it prefer to wait until the text of these resolutions has been printed in the *daily Journal* of the session?

Some members. — Vote at once.

Other members. — Wait till tomorrow

The President. (In French.) — As there is a difference of opinion, I request the meeting to settle the question by a vote.

I now put to the vote the proposal, that we should at once deal with the conclusions proposed by Messrs. Evelyn Cecil and Fairfax Harrison.

— This proposal is adopted.

The President. (In French.) — I now put to the vote, paragraph by paragraph, the proposed conclusions which are as follows :

" Subject to the particular conditions affecting railroad accounting resulting from control of, or financial interest in, the railways by the State.

" The Congress finds that :

" 1° Statistics, to be of value for operating purposes, should be made available for the operating officers at the earliest practicable date after the performances of the services for a given period."

— Adopted.

" 2° To be of greatest value from an economical operating standpoint, statistics prepared for operating officers should include only such costs as are directly incurred by the officer interested, and all indirect costs should be separated therefrom."

— Adopted.

" 3° No one line of statistics should be exclusively relied upon, but statistics reflecting all factors essential to revenue and costs, should be prepared and properly considered."

— Adopted.

" 4° The respective statistics of railway administrations are based on principles suitable to their varying conditions, but the circumstances and conditions of working necessarily differ in different countries, and it is practically impossible to arrive at an absolutely uniform system of operating statistics applicable alike to all countries."

— Adopted.

The President. (In French.) — Mr. Appleyard proposes an additional paragraph which runs as follows :

" The statistical returns of railways would be of much greater value if they were based on a uniform system, on the locomotive-kilometre, the train-kilometre or other unit. In compiling these statistics, it is advisable that there should be uniformity from the point of view of expenses, of amortization and of renewals, in the capital accounts."

Mr. Bloch. (In French.) — Paragraph 4 of the conclusions we have just adopted concludes as follows :

" It is practically impossible to arrive at an absolutely uniform system of operating statistics applicable alike to all countries."

Now the proposed wish expresses the contrary.

Mr. Acworth, *reporter.* — It is not accurate, as Mr. Bloch has stated, that Mr. Appleyard's wish is in contradiction with the conclusions adopted by the section. Clause 4 merely states that it is practically impossible to arrive at a uniform system for all statistics, while Mr. Appleyard states that it would be useful to unify certain well-defined groups. I think that there can be no

reasonable objection to Mr. Appleyard's amendment, seeing that it is certainly desirable, within the limits realizable in practice, to obtain some uniformity as regards some chief points.

The President. — Perhaps Mr. Appleyard will not insist that his amendment should be put to the vote if I in the first place brought before the meeting some other conclusions proposed by Messrs. Timonoff and von Strigl; it seems to me that his amendment is rendered to some extent useless by the other conclusions, which are in the direction of asking, the one the Permanent Commission of the Congress, the other the Central Office at Berne, to act in a certain way as a centralized bureau for collecting uniform statistical information about the railways of the different countries.

The first runs as follows :

" It is desirable that the initiative already taken by the Swiss Federal government in calling a special international conference with a view to a unification of railway statistics should result, in as short a period as possible, in the establishing of railway statistics making it possible easily to compare at least the principal elements of the working of the iron roads in the different countries."

The second runs as follows :

" Considering that the data making it possible to establish international statistics are lacking and cannot become available for a long time to come, the Congress nevertheless considers it desirable that the Permanent Commission should investigate whether it would not be advisable and whether it would not be possible to collect and publish certain important, but summary statistical data about the State railways belonging to the Congress.

" These statistics should include, in particular, the actual length, the length of lines in operation, the capital outlay, the quantity of rolling stock, the mileage of that rolling stock, the number of the passengers, the tonnage of goods carried, the total receipts and expenses and, finally, the definite financial results obtained by the companies."

Mr. von Strigl. (In German.) — I will content myself with the statement that the two conclusions can be adopted without disadvantage, for there is no contradiction between them. As far as I am concerned, at least, I will vote without hesitation both for Mr. Timonoff's proposal and for my own. As regards mine, it is a question of preparing as soon as possible some information essential for international railways statistics. That result can, in my opinion, be obtained in a comparatively short time.

As regards, on the other hand, the proposition to establish a uniform basis for real international railway statistics, I think that we are unanimous in thinking that long years will pass before any tangible result can be obtained and if in the meantime the organization, which in my opinion, and according to the conclusions already voted, seems to be the best prepared, immediately starts on the work and carries out the programme which is rapidly realizable, I think that this does not in the least prevent that the organization mentioned by Mr. Timonoff should devote itself to the arduous task, which

certainly will take long years, which consists in comparing the statistics with each other and establishing international railway statistics.

Mr. Timonoff. (In French.) — I share Mr. von Strigl's opinion. I shall vote for his proposal as well as for mine, because the two proposals supplement each other.

The Swiss government has already taken the initiative and called an international conference; we can but applaud this. On the other hand, it is said that the Permanent Commission of the International Railway Congress could work in the same direction. I equally applaud that proposition, and I think it advisable that both should be adopted.

Mr. Riché, French Eastern Railway. (In French.) — According to Mr. Timonoff's last statements, it seems that his proposal is modified, and that he recommends the adoption of both proposals. There might be serious disadvantages in entrusting to two different bodies the work of elaborating a statistical programme and of laying down the principles.

It might happen that the conclusions of the two bodies differed, and this would retard the solution of the question.

If quick progress is to be made, a single body must be entrusted with the investigation of the question and not two bodies, which while working along parallel lines, might arrive at contradictory results.

Mr. Timonoff. (In French.) — I have not proposed that the work should be entrusted to any permanent body; I have drawn the attention of the Congress to the fact that the Federal government had already proposed the calling of a conference.

All the powers invited have answered in the affirmative; there is only one country, France, which has not yet given its assent.

We wish for a quick solution; there is the preliminary work which has been done and which has taken about three years. I think that the Congress should take this opportunity to encourage the Federal government in its enterprise; but, on the other hand, I see no reason why the Permanent Commission of the Congress should not thoroughly investigate the question which is a very important one and will take much time.

Mr. von Strigl. (In German.) — I would remark that the fear that there might be differences between the results of the work of the two bodies has no justification. Apart from the case, which I have not considered, that Mr. Timonoff's proposal would give results in the more or less near future, it must be remembered that my proposal is that statistical data should be collected and published, while the other aims at the establishment of a scheme of statistics; and when this has been done, there will of course be a comparison of the results obtained in both cases; and after that the work will be entrusted either to Berne or to Brussels.

The objection has been raised that one State has not yet notified its adhesion to the proposition, and I ask you to take due note of this. Austria has notified its adhesion to this measure only under condition that it will be accepted at least by all the States who have signed the International convention for the carriage of goods on railways. I think that Germany has made the same reservation. Thus up

till now the different States are not even unanimous You will, hence, note that this question of form is not yet solved. If we adopt only Mr. Timonoff's proposal, the realization of my project, which is more modest, relating to international statistics, is thereby put off for many years. Now I do not at all see why one of the two organizations would not be able to collect information quickly and work in a way practically, while the other would make investigations and work at the theory; nor do I see why there should be any conflict.

Mr. Fairfax Harrison, *vice-president*. — While I do not question the advantages of any intelligent statistical enquiry, the propositions of Messrs. Timonoff and von Strigl are, I submit, unnecessary at this time, because their objects would seem to be accomplished either through the discussion in the international conference which we have been advised the Swiss government proposes to convene on the subject of railway statistics, or because it is probable that a further study of the question can be counted upon at the next session of this Congress, by reason of the interest shown in the present debate.

The American railways have only recently entirely readjusted their system of accounts to comply with the requirements of the Interstate Commerce Commission under the provisions of a recent law. So far as they are concerned it would, therefore, be legally impossible for them to give adherence to any modifications in their present system which might be recommended in an international interest, and in any event they would deprecate the disturbance of an understanding which, with much compromise of opinion, they have established with their government, through an attempt to effect a uniform system of statistical accounting applicable to all the countries of the world, a consummation which, in any event, it is recognized is practically impossible.

The President. (In French.) — I think that the discussion may be closed. I put Mr. Timonoff's proposal to the vote; you know how it is worded.

— This proposal is not adopted.

The President. (In French.) — I put Mr. von Strigl's proposal to the vote; it has also been read out.

— This proposal is not adopted.

Mr. Appleyard. — I withdraw my proposal.

The President. (In French.) — As Mr. Appleyard has withdrawn his proposal, we still have left the last proposal of Mr. Bloch, asking that the agenda for a future session of the Congress should include the study of the internal statistics which companies keep-for their own proper use, so that the experience of everybody might be turned to profit.

Does anybody second this proposition? (*Silence.*)

As nobody seconds this proposition, it is not put to the vote.

DISCUSSION AT THE GENERAL MEETING

Meeting held on 14 July 1910 (afternoon).

MR. P. WEISSENBACH, PRESIDENT, IN THE CHAIR.

GENERAL SECRETARY : MR. L. WEISSENBRUCH.

FIRST ASSISTANT GENERAL SECRETARY : MR. MÜRSET.

SECOND ASSISTANT GENERAL SECRETARY : DR. A. BONZON.

Mr. Bloch, *principal secretary of the 4th section*, read the

Report of the 4th section.

(See *Journal de la huitième session*, No. 9, p. 3.)

" Mr. ACWORTH (*reporter for Great Britain*) criticized the want of principle in the English statistics and of logic in the way in which they were drawn up. He regretted above all the absence of any indication of the passenger and goods mileage; the numbers of passengers and of tons consigned were alone given. A committee had been recently appointed to lay down the form of statistical returns; but there had been no majority in favour of specifying mileage returns.

" Sir Thomas Rees PRICE (*reporter for the British colonies*) urged the utility of statistics based on a system which would enable different railways to be compared, and emphasized the distinction to be drawn between the definite statistics intended for publication and the provisional statistics intended day by day to inform the head of the different departments how matters were progressing.

" Mr. COUNTY (*reporter for America*) set forth that a new law had given the Interstate Commerce Commission of the United States the power of fixing the form of the statistics and that this had come to an agreement with the railways on the subject. He drew attention to the necessity of having the statistics drawn up by men perfectly acquainted with the services concerned. Finally, while he desired that practice should be uniform, he drew attention to the danger of rules which would hamper proper financial management, by compelling all improvements to be charged to capital account.

" Mr. BARRIOL, who had been appointed reporter for the other countries at a late

date to replace the reporter who had died, limited himself to indicating the logical principles on which statistics should be based.

" Messrs. Frolof (*Moscow-Vindau-Rybinsk Railway*), Timonoff (*Russian government*), von Zluhan (*Wurtemberg State Railway*), von Strigl (*Austrian State Railway*), Rathgeb (*Swiss government*), and Brandt (*Russian State Railway*) urged the great usesfulness of statistics which would make comparison between different countries possible. In order to obtain them, Mr. Timonoff proposed that the steps taken by the Swiss government to summon a conference in order to establish an international agreement should be supported, and Mr. von Strigl proposed that the Permanent Commission of the Congress should be instructed to institute international statistics, utilizing the parts common to the internal statistics of the different countries.

" The discussion on the usefulness of establishing passenger-mile and ton-mile statistics was very animated. Sir Charles Owens (*London & South Western Railway*), Messrs. Sam Fay (*Great Central Railway*), Evelyn Cecil (*London & South Western Railway*), Jacomb-Hood (*London & South Western Railway*) and Alfred Aslett (*Furness Railway*), in the name of the English railways, as well as Mr. Henry C. Allen (*Buenos Ayres Great Southern Railway*) and Colonel Bonham Carter (*Madras & Southern Mahratta Railway*) disputed the possibility of compiling such statistics in a proper manner, at least in England, owing to the way the different railways were mixed up, and that of drawing any useful information from them, owing to the diversity of all the factors which went to make the average. Messrs. Hale (*American Railway Association*), Patterson (*Pennsylvania Railroad*), Voorhees (*Philadelphia & Reading Railway*), Plant (*Southern Railway, United States*), Mahl (*Union Pacific Railroad*), in the name of the American railways, and Colonel Haines (*United States government*) and Mr. Appleyard (*Central South African Railway*) emphasized the benefits gained from such statistics in comparing different railways together. Mr. Acworth (*reporter*) laid stress on the disadvantage that the English railways were the only ones who did not draw up such statistics.

" The section decided on the following conclusions :

DRAFT CONCLUSIONS.

" Subject to the particular conditions affecting railroad accounting resulting from control of, or financial interest in, the railways by the State.

" The Congress finds that :

" 1° Statistics, to be of value for operating purposes, should be made available for the operating officers at the earliest practicable date after the performances of the services for a given period.

" 2° To be of the greatest value from an economical operating standpoint, statistics prepared for operating officers should include only such costs as are directly incurred by the officer interested, and all indirect costs should be separated therefrom.

" 3° No one line of statistics should be exclusively relied upon, but statistics reflecting all factors essential to revenue and

costs, should be prepared and properly considered.

" 4° The respective statistics of railway administrations are based on principles suitable to their varying conditions, but the circumstances and conditions of working necessarily differ in different countries, and it is practically impossible to arrive at an absolutely uniform system of operating statistics applicable alike to all countries."

Mr. Timonoff, *vice-president of the 4th section.* (In French.) — The discussion of the question of statistics at the meetings of the 4th section has given the Congress an opportunity to give an opinion about the usefulness or uselessness of noting a tendency towards the unification of railway statistics in the different countries.

Several members have thought that one should not limit one-self to the statement that as the conditions of working of railways differ, statistics should differ equally; but it is necessary that the Congress should show that its ideal would be to see an agreement about this point, between the different countries.

In agreement with several of my colleagues, Messrs. Elsner, Pichler von Deeben, Taris, Biedermann, I propose to add a paragraph in this sense to the conclusions, a paragraph which is worded as follows :

" It is, however, desirable to encourage all efforts towards unification of railway statistics having the object of making possible easy comparisons of the main elements of railway operation in different countries. " (*Applause.*)

Mr. Evelyn Cecil, *vice-president of the 4th section.* — I do not want to discuss in the full session the question which was fully treated in the sectional sitting.

Many of our British and American colleagues are absent on the understanding that a compromise had been arrived at, and would be adhered to, and no notice was given till yesterday that any alteration would be proposed. They could not be aware earlier that Mr. Timonoff desired to add this paragraph. It was only after many difficulties that agreement was obtained upon the four conclusions submitted to the Congress, and these conclusions are the result of a compromise by those present at the full discussion.

Messrs. Fairfax Harrison and Sir Charles Owens, who took an active part in it, are not here. They might reasonably protest against a proceeding which consists of proposing in full session an amendment to the conclusions which was only printed yesterday in the daily journal of the session. If they had known that this new proposal was to be made, they would probably have stayed in Berne.

I ask the Congress in consequence to reject the amendment.

Mr. Hale, American Railway Association. — I regret that so many of the Americans are absent, but I want to say for them and for myself that we understood that the compromise accepted by the section was practically final.

Among the absent American delegates there are many who believe in international statistics but they feel that a proper concession was made by the adoption of the suggestion of Mr. Bloch, in accordance with which the Permanent Commission was asked not to lose sight of the question, but to bring it up again at the next session of the Congress.

Mr. Gooday, Great Eastern Railway, Great Britain. — I beg to say I am in perfect agreement with Mr. Cecil's proposal; as I consider it would be more correct and represent the actual situation if No. 5 were not accepted. I should be glad if Mr. Timonoff would, in this sense, withdraw his proposal.

Mr. Timonoff. (In French.) — I cannot agree to this request. The sole argument brought forward is this : one should not, at the general meeting, make any modifications in the resolutions adopted by the sections.

Now this is quite inaccurate and contrary to the practice of the previous congresses. The general meetings would have no reason for their existence if the decision of the sections merely have to be ratified, pure and simple.

I regret that a certain number of colleagues interested in the question have had to leave Berne, but that is no reason why we should give up discussion at the general meeting. That would be a bad precedent which could be invoked in questions of greater importance. (*Very good.*)

Mr. Evelyn Cecil. — I resist the amendment not merely because certain of my colleagues are absent in view of the compromise, but also because the proposition was not in the least discussed in the section. Several absent members, if they could have anticipated that such a proposal would be moved in the full assembly, would have made a point of coming to resist it. The four conclusions adopted by the section are the result of a compromise, and the fifth which it is desired to add upsets the whole basis of the resolution.

Mr. Colson. (In French.) — As president of the 4th section, I think I must remind you of the conditions under which the conclusions were voted, although I have only semi-officially intervened in the compromise which has just been referred to.

The reason which led the 4th section to reject any proposals having a bearing similar to that of Mr. Timonoff was the extreme difficulty of compiling any statistics which would be really comparable. Personally, I became fully convinced of this difficulty when I tried to make a comparative study of the railways of different countries.

The English railways have statistics which differ materially from those of administrations on the Continent; and the delegates of those railways declared that they would have great difficulty in modifying them.

In America you know that the legislature has given full power to the Interstate Commerce Commission to settle in what form railway statistics are to be kept, and inflicts severe penalties on those who would keep accounts other than those authorized. In order to settle the form of those accounts, there have been very lengthy negociations between the Interstate Commerce Commission and the representatives of the American railways, and it is natural that some of those representatives should feel somewhat alarmed when they see proposals made liable to lead to discussions which may endanger the agreement which has been arrived at with such difficulty.

Other members of the Congress have remarked that the French railways, owing to the conventions existing between them and the State, which gives them a guarantee

for a rate of interest, have in their turn no freedom of action as regards the modification of their system of book-keeping, and their statistics are necessarily based on the rules in force concerning the calculation of the receipts and expenses on which the guarantee is based.

No doubt the resolution proposed by Mr. Timonoff will not be considered very compromising, as it limits itself to the expression of the wish that attempts should be made to uniformize international statistics. Such uniformity would be unquestionably advantageous. The question is whether, if we adopt this resolution, we can hope to arrive at any practical result and whether this wish will not remain purely platonic.

Under these conditions the section did not think it advisable to express a wish of this kind at a meeting of business men, whose deliberations tend to the making of practical improvements rather than the expressing of wishes of a theoretical order.

These are the remarks I wished to make to the Congress, in order to make clear why the 4th section has not added to its conclusions a fifth paragraph of the kind proposed by Mr. Timonoff, altough it has no fundamental objection to the idea expressed by him.

Colonel Bonham Carter, Madras & Southern Mahratta Railway. — I recognize that the Congress has the right to modify the conclusions adopted by the sections and that Mr. Timonoff's proposition would perhaps facilitate the comparison of the statistics, but I think I must mention that a similar proposal has already been made by Mr. Timonoff and that the 4th section did not accept it for the following reasons: a recent law compels the railways of the United States to modify their system of accounts and statistics. A bill is at present being submitted to the British parliament, and if it should be passed, the English companies will be in very much the same position. Finally, you have just been informed how the French railways are situated in this respect.

If conclusion 5 as proposed should be adopted, it would have no effect as regards a large number of companies and would have no use except possibly from an educative point of view. I think therefore that it would be inadvisable to adopt this resolution.

Mr. Evelyn Cecil. — Mr. President, in the circumstances in which we find ourselves, and bearing in mind that the conclusion has not been discussed in the section, it appears to me very difficult to arrive at agreement here. But I do not wish to raise undue difficulties, and I therefore propose the following words upon which I think it might be possible to obtain unanimity :

" 5° It is, however, desirable to encourage efforts towards unification of railway statistics at least so far as the main elements of railway working are concerned, to the extent to which this is possible, having regard to the necessities of each country."

Mr. Timonoff informs me that he agrees to this wording. (*Cheers.*)

The President. (In French.) — As Mr. Timonoff agrees to accept the text proposed by Mr. Evelyn Cecil, and as no remarks are brought forward, I declare this text adopted.

The following are accordingly the

CONCLUSIONS.

" Subject to the particular conditions " affecting railroad accounting resulting " from control of, or financial interest in, " the railways by the State.

" The Congress finds that :

" 1° Statistics, to be of value for operat- " ing purposes, should be made available " for the operating officers at the earliest " practicable date after the performances " of the services for a given period.

" 2° To be of greatest value from an " economical operating standpoint, sta- " tistics prepared for operating officers " should include only such costs as are " directly incurred by the officer inte- " rested, and all indirect costs should be " separated therefrom.

" 3° No one line of statistics should be " exclusively relied upon, but statistics " reflecting all factors essential to reve- " nue and costs, should be prepared and " properly considered.

" 4° The respective statistics of railway " administrations are based on principles " suitable to their varying conditions, but " the circumstances and conditions of " working necessarily differ in different " countries, and it is practically im- " possible to arrive at an absolutely uni- " form system of operating statistics ap- " plicable alike to all countries.

" 5° It is however, desirable to encour- " age efforts towards unification of rail- " way statistics at least so far as the main " elements of railway working are con- " cerned, to the extent to which this is " possible, having regard to the necessi- " ties of each country."

— The conclusions were adopted.

APPENDIX

[313 .385. (01]

MEMORANDUM

By Jean de RICHTER,
ASSISTANT MANAGER OF THE NORTH WESTERN SYSTEM OF THE RUSSIAN STATE RAILWAY.

SUMMARY.

1. — *Author's note and introduction.*

2. — *Principles of statistics of railways in operation.*

a) General remarks.
b) Accounts.
c) Figures relating to maintenance of permanent way and rolling stock.
d) Statistics of the volume and character of the traffic carried.
e) Unit statistics as applied to volume of traffic, etc.
f) Statistics of cost of operation.
g) Statistics relating to indirect and subsidiary services.
h) Other miscellaneous statistics.

3. — *Uniform classification of working expenses.*

4. — *Conclusions.*

5. — *Annexes.*

FIRST PART.

Author's note and introduction.

The Permanent Commission of the Congress, in formulating the programme of each session, and in entrusting the preparation of the various papers to the reporters chosen from among the representatives of the railways of the Association, has been desirous of ensuring their complete independence in the accomplishment of their task. This very liberal proceeding has doubtless produced excellent results; but as a matter of course each reporter, inspired by the ideas and experience of his own country, has endeavoured to bring into special prominence the more salient points

of view of his compatriots. Everything, however, has the defects of its qualities, and this method of procedure has created difficulties when, in the course of the discussions at the Congress, one has found oneself confronted with papers on subjects which, although identical in character, have been treated in absolutely diverse fashion. Although the report on statistics for the European countries, including Russia, has been confided to a special reporter, we feel that we ought not to neglect an opportunity of furnishing our contribution to the study of a question of very great interest being of opinion that in our quality of Russian we can discuss the question with full independence so far as concerns our own country, whilst adopting the programme laid down in the paper of Sir Thomas Rees Price appearing in the *Bulletin of the Railway Congress*, and first in date of the works dealing with railway statistics (1).

Metho adopted drawing the mer randur

Being without the qualification of reporter, we have not made any inquiries of the Russian administrations, but have simply applied ourselves to the task of placing in evidence the practice followed by the Russian system, comparing it as far as possible with the practice of the British colonial system, between which and the Russian there exists a certain analogy; in point of fact, the Russian government works directly the greater part of the lines, and reserves to itself a considerable share in the management of the affairs of the private companies, to which it often accords its financial guarantee, and over which it exercises a close supervision.

SECOND PART.

Principles of statistics of railways in operation.

a) **General remarks.** — Considerable attention is given by the Russian system to statistics, alike as regards the State Railway and the companies. Certain railways have, indeed, earned distinction in this sphere, notably the former Great South Western Railway Company of Russia, the Kharkoff-Nicolaeff lines, forming today part of the southern Russian state system, and many others which devoted themselves to statistical investigations of all kinds, more than thirty or forty years ago. It would be very interesting to deal with the historic aspect of this evolution; but as space is lacking we will only take into consideration the present state of affairs, characterized rather by a superabundance of statistical work than by a system solidly based and properly unified.

The State system, being under the guidance of three ministries or general managements (ways of communication, finance, and court of accounts) is called upon to prepare special statistics for the use of these different ministries or general managements, independently of the data serving for its own use and recorded

(1) December 1909, p. 1569.

in periodical reports, annual returns, etc. According to a list which we drew up at the beginning of the year 1910, the statistical tables, permanent and temporary, furnished by the administrators of each system amount together to a total of 239 abstracts or vouchers, which may be classified as follows :

	Per cent.
Statistics of balance-sheet : assets	32
— — — : liabilities. . .	8
— — revenue	19
— — expenditure	20
— — results of working.	19
— — accidents.	1
Other data.	1
Total. . .	100

As these statistics play a subordinate part, so to speak, to the tables (I-XI) of general statistics of the Ministry of ways of communication (annex I to the present memorandum) the question arises as to what is their real function. This being, properly speaking, only a systematic division into their constitutive elements of general data bearing upon the annual finance and general results of each system (treated as a unit), we arrive at a classification of the elements as follows :

		Per cent.
1.	Analysis of length and area of surfaces.	15
2.	— of inventory	32
3.	— of staff.	6
4.	— of traffic.	13
5.	— of directions of traffic (up and down)	4
6.	— of accidents.	3
7.	— of duration of commercial or technical transactions . . .	25
8.	— of other elements	2
	Total. . .	100

With a view to facilitating the study of a question already very complicated by its nature and by the number of elements entering into its composition, we commence by dividing the corresponding data into *permanent* statistics and *temporary* statistics, following the example of Sir Thomas Rees Price.

Permanent statistics.

The permanent statistics, comprising, in accordance with the formula of Sir Thomas Rees Price, the actual results, abstracted, grouped, and presented when once the operations concerned are over, are more especially those which relate to annual periods and are recorded in the returns of the ministries of communications, of finance, and of the managements of each individual system for the financial period entering the space of a complete year.

In our report on the question of railway accounts, contributed to the seventh session of the Congress (question XIV), we have already furnished a general idea of the statistical items chronicled in the returns (1), dwelling upon their extreme complexity and lack of unity. In taking up again, the same subject on the lines adopted by Sir Thomas Rees Price, we hope to make more clearly evident all that is defective in the present system of Russian railway statistics.

Temporary statistics.

According to a table prepared by us at the beginning of the year 1910, the number of temporary statistics reaches the very

(1) Appendix VI to our report (see *Bulletin of the Railway Congress* 1905, March, p. 1037, and *Proceedings of the seventh session* [Washington, 1905], vol. 3, p. XIV-149).

considerable total of 139 abstracts or vouchers, including: *a*) generalities, 4; *b*) finance and accounts, 31; *c*) ways and works, 4; *d*) rolling stock and workshops, 22; *e*) methods of correspondence (post, telegraph, telephone, signals, etc.), 2; *f*) stores, 5; *g*) staff, 21; *h*) commercial and technical working, 44; *i*) accidents, damages, losses, etc., 4.

According to the dates of their presentation, these statistical data are classed in the following fashion: *a*) accidental, *i.e.*, presented as the need may happen to arise, 18; *b*) daily, 5; *c*) weekly, 1; *d*) presented fortnightly, 3; *e*) monthly, 61; *f*) quarterly, 4; *g*) half-yearly, 22; *h*) annually (without entering into the category of permanent statistics), 36; or in all (without counting the data of an accidental character), 2,773 abstracts per annum.

It would be useless to enter into the details of temporary statistics which are remarkable only by their absolute lack of cohesion. We confine ourselves, therefore, to pointing out that a scheme of temporary statistics, based on a general view, is now in preparation, a scheme of which we give a brief idea in annex III to our memorandum.

Establishment and balance-sheet accounts.

b) **Accounts.** — As no one doubted the great importance attaching to an exact knowledge of the expenditure necessitated by the construction and improvement of railway systems, a commission, appointed in 1884, introduced a classification of the figures relating to the establishment expenses and the balance-sheet of railway companies, forming annexes IX to XIV to our report on the question of accounts. These establishment expenses are, however, only imperfectly known, and are not always found recorded in the balance-sheets of the undertaking, especially after the buying-up of a considerable number of privately-owned railways and the successive grouping of these lines among the different systems of the State. This deplorable confusion has been aggravated by the practice of debiting establishment accounts with fictitious items of interest added to the expenditure effected upon the resources of the revenue or State budget, where the obligation of paying interest for the use of the capital was in no way demonstrated. It is due to this circumstance that wholly erroneous conclusions have been arrived at concerning the financial results of the working, a fact which has lately been established by a commission of inquiry appointed by the Russian government in 1908. Thus the value of the balance-sheet appended to the returns of the State systems, where the subject has never received the attention to which it was entitled, is practically nil. The liabilities being surcharged with fictitious expenditure, the assets do not admit of a detailed analysis of the real value indicated by the inventory, in which the cost of the permanent way and constructive works, buildings, etc., is found burdened with the value of rolling stock, general expenses and costs of consolidation of capital, stocks in warehouse, etc.

It is only from 1 January 1911 that the government has introduced a uniform type of balance-sheet for the whole State system.

If there is one thing the importance of which is thoroughly understood in Russia, it is the necessity for an exact classification of receipts and expenses, uni-

form for the whole system operated by the State and the companies. All the headings of the budget have been fixed by a commission appointed by the government in 1884 (1), and this nomenclature is recorded in annex III to our report upon Russian railways accounts. But this uniformity of classification in no way implies the material unity of the accounts, since a great difference exists between the methods of charging revenue and expenditure in force upon the State lines and those of the companies. The State systems count as revenue or expenditure only the money actually received in cash or expended, a vicious practice borrowed from the government accounts, whereas the companies enter, and rightly so, as Sir Thomas Rees Price remarks, all the receipts and all the expenses appropriated, whether received or not, a method which alone responds to the principles of sound book-keeping. This difference in the method of charging involves, at the same time, another difference : the closing of the budget, which occurs on the State system three months after the expiration of the financial year, takes place in the case of the companies only at or about the moment of the settlement of the report and accounts for the financial year, *i. e.* at a period much more remote. We may here remark that we have no objection to raise with regard to the desiderata urged by the reporter in paragraphs 1, 2, 3, 4, 5, 6, 7. pages 12 to 14, of his paper.

sifica-
n of
ffic
ings.

Receipts. — We believe that the classification of receipts, given in annex III to our report on accounts (scheme of traffic budget) corresponds in fairly exact fashion to the wishes expressed by Sir Thomas Rees Price.

Classification of working expenditure.

Expenditure. — We have given in annex III to our paper on accounts our classification of expenditure, which does not differ greatly from the ideas of the honourable reporter. It goes without saying that, applied to systems of lesser importance, this classification involves a certain excess of detail, and a commission, instituted by the government — a commission whose labours are drawing to a close — has proposed to eliminate from the present classification headings of a secondary importance, which will diminish by about two-thirds the number of items in the budget of expenditure.

General statistical data on the construction and working of the Russian railways.

Before entering into the details of the data recorded by Sir Thomas Rees Price, on pages 16 and 17 of his report, we think it well to give a general idea of the particulars contained in eleven tables of an annual statistical miscellany, prepared by the ministry of ways of communication upon the basis of special data furnished by the managements of each system.

Annex I to the present memorandum.

I. Financial position of the railways at the end of the year (38).

II. Length of railways in regular operation at the end of the year, constructed, operated, length of application of tariff, and virtual length by sections, with indication of the year of construction (9).

III. Rolling stock of the railways :

A. Stock of locomotives upon the railways at the close of the year, with indication of their number, their type, method of

(1) See page 151 of our report (*Bulletin of the Railway Congress*, 1905, March, p. 1039).

heating according to fuel, and system of brakes.

B and *C*. Stock of carriages and goods wagons on the railways at the end of the year, with indication of number, design and cost (131).

IV. Effective force of the staff and its maintenance on the railways.

V. Mileage of the rolling stock on the railways during the year (78).

VI. Number, mileage and composition of trains during the year, with analysis according to fast, ordinary and slow trains, per month (93).

VII. Traffic and gross receipts during the year, with analysis per month of the total passenger traffic, according to the general tariff for goods by slow-freight trains and the total gross receipts (188).

VIII. Working expenses during the year (146).

IX. General results of the working and traffic, during the year (89).

X. Accidents during the year (80).

XI. Number of persons affected by accidents during the year (93).

(See annex I to the present memorandum).

Annex II to the present memorandum.

With regard to the schemes elaborated by the commission of 1884, these include ten tables forming an annex to the returns for the financial year, *viz.* :

I. General data regarding the line, including an indication of the date of the concession, the opening, and likewise the length of the working and application of tariffs.

II. Total length of main lines, secondary lines, and branch lines belonging to the company and to third parties.

III. Data regarding rails and sleepers.

IV. Data regarding the permanent way and the number of constructive works, level crossings and accessories of the permanent way, situated outside the stations.

V. Data regarding the lands acquired for the construction of the line, the number and description of the buildings and their appendages.

VI and VII. Data concerning the number and type of locomotives, carriages and wagons, and of installations for their upkeep and repair.

VIII. Data regarding the number and stocks of tools of the central and auxiliary workshops.

IX. Data regarding commercial transport capacity.

X. Data relative to the traffic, revenue, and mileages of the rolling stock.

(See annex II to the present memorandum).

The commission of 1884, in formulating this programme, left to the ministry of ways of communication and to the general Russian railway association the task of completing it by a series of supplementary tables of a " technical or administrative " character.

The general association concerns itself very little with the matter. As to the ministry of ways of communication, it hands over the task to the general management of the State railway and to the boards of directors of the privately-owned railways.

Neither the one nor the other devotes

to this work the care demanded by the importance of the subject. As to the practice of the administrations of each individual system, the question is disposed of in a rather unexpected fashion. The statistical tables of the commission of 1884 are buried under a mass of miscellaneous particulars having no apparent link with the programme of the commission of 1884, of which there remain today only certain fragments and that medley of forms and annexes to the returns which we have recorded in our report on Russian railway accounts (*Bulletin* of March 1905). (See annex VI.)

These particulars of a general character being given, we take up again the thread of our inquiry, following the programme outlined by Sir Thomas Rees Price, with the object of entering into greater detail. From this time, then, let us occupy ourselves only with the data recorded in the annual traffic returns issued by the managements of each system, independently of the general data published by the ministries of ways of communication and finance.

Statistics of assets.

c) **Figures relating to maintenance of permanent way and rolling stock.** — We have already dwelt upon the defects in the first establishment accounts, for which the commission of 1884 furnished, nevertheless, a fairly detailed model. Unfortunately, a large portion of the present system was then already constructed, and the rules and regulations elaborated by the commission (except as regards the classification of receipts and working expenses) not receiving any sanction, no one believed it necessary to take heed of the counsels given. Not only did the private railways continue to act in this way, but the State system, whose accounts were always very much in arrears, did the same. A good deal of the responsibility for such a condition of affairs rests upon the system of accounts adopted by the State, which is based solely upon the operations of cash finance, and still more upon the out-of-date organization of the accountant-general's office in matters relative to the administration of railways.

If such are the characteristic features of the establishment accounts (and of the corresponding portion of the balance-sheet), nothing is more natural than the insufficiency or defectiveness of the statistical details furnished by the returns of each administration. Here are the elements we which have found again among the particulars furnished by the State system and the companies.

Permanent way and accessories. — General data. — By way of explanatory note and entry for the subject, a statement is made of the length, highest point, steepest gradient, radius of sharpest curve, virtual length and average cost of each system, including general workshops, rolling stock, etc.

System belonging to the administration. — Table indicating the mileage of single, double and triple track, and of sidings, etc., together with the equivalents in single-track mileage for the whole system or by sections, according to circumstances.

Average mileage operated. — This information is likewise recorded in the returns for the financial year.

Rails in track. — Table showing for each section the total mileage of rails of each type, according to weight, length per unit, and date when laid.

Sleepers. — Statement showing for each section the number of sleepers of each sort and the period they have been in use, without indication of the corresponding mileage or of the number per verst, etc.

Rail fastenings. — Statement showing for each section the type of attachment, without indication of the mileage of line or age.

Ballast. — Statement showing the nature, depth, etc. of the ballast used, without indication of the mileage of the line on which it is used.

Bridges, tunnels and other constructive works. — Dimensions and capacity, without indication of the cost for each section.

Reservoirs and dams. — Nil.

Hoisting plant. — Certain data (without indication of price) and only for the workshops for the repair of rolling stock.

Coaling plant. — Nil.

Station and other buildings used for railway purposes. — Particulars for each section and station, under classes, but without indication of cost.

Signalling appliances. — Particulars for each section and station, under classes of signals, but without indication of cost.

Land acquired for railway purposes. — Nil.

Locomotives and rolling stock. — Locomotives. — All the particulars mentioned by Sir Thomas Rees Price are given under the separate types.

Coaching stock. — Ditto.

Goods stock. — Ditto.

Workshops and other plant and machinery. — Ditto, except as regards the age and cost of plant.

As regards the condition of the plant and equipment, belonging to the statements of account and the temporary statistics, the indications given are sufficiently detailed to meet in an adequate way the suggestions of the reporter.

d) **Statistics of the volume and character of the traffic carried.** — This is, perhaps, the most highly-organized section of the whole of the Russian railway statistics. Centralized in the ministry of finance, to which belongs the supreme direction of the tariff arrangements of the whole system (State and companies), this portion of the statistics, arranged upon a plan marvellously complete, clear and uniform, is yet of little practical value, since the data, published more than a year after the close of the financial period, clearly cannot serve as a guide in the conduct of current affairs, in regard to which it is necessary to come to a decision based upon temporary statistics gathered together for the occasion.

A. Statistics published by the administrations of each system.

In accordance with an instruction approved by the minister of finance relative to the establishment and publication of traffic statistics, all the railways of the Empire (State and companies) are obliged to keep detailed statistics of the traffic in passengers, luggage and goods by quick freight and slow freight.

The passenger statistics are based upon a classification of passengers and luggage according to scales, whilst the goods are divided into three categories (I, II, III) and under 129 distinct headings.

These statistics, prepared by the administration of each system, are published in the form of annual miscellanies :

I. Statistics of the commercial goods

traffic, slow freight of the 1st, 2nd and 3rd categories, with the exception of cereals and of all goods by fast and ordinary services, conveyed by passenger and mixed trains "at departure" by each station of the system.

This statement includes particulars of the consignments from all the stations of the line in question and for all the goods in conformity with the classification, grouped into certain categories. It further includes columns in which are recorded transports by the piece and live stock.

These statistics include the following details :

1° Name of sending station;
2° Route;
3° Name of receiving line;
4° Name of receiving station;
5° Volume of goods :
a) Consigned to stations of the system proper, and to other lines;
b) Total for each receiving line;
c) Total per sending station.

II. Particulars of the transports of cereals "on departure" from each system of the station proper. This group of figures contains data concerning the dispatch of all cereals, divided into four categories :

a) Corn;
b) Flour, groats, malt and oatmeal;
c) Bran and residues;
d) Seeds.

In accordance with this classification of goods, the tables contain thirty-seven columns, and the particulars entered therein are classed according to :

1° Sending stations;
2° Points of exchange of goods;
3° Receiving lines;
4° Receiving stations.

The statement includes the totals for each category and for the whole (general total) "on departure".

III. Statistical statement of the commercial activity of the system, containing general abstracts of the passenger, luggage and goods traffic by all classes of trains per annum.

This collection of figures includes the following particulars :

1° General survey of the commercial activity of the system;

2° Table showing the number of passengers and the volume of luggage and goods by quick freight and slow freight per month, a comparison being made between the figures for the current financial year and those of the preceding years;

3° Table showing the passanger, luggage and goods traffic by the local service "on departure", "on arrival", and "in transit", as compared with the figures of the three preceding years;

4° Table of station operations "at departure" and "on arrival" of passengers and of goods by quick and slow freight;

5° Table of service traffic, with groups and headings for the classification of commercial goods, a comparison being shown with the figures of the preceding years;

6° Table dealing with the number of luggage-tickets and way-bills of goods by quick and slow freight according to station, as compared with the figures of the preceding years, and

7° Table of the traffic in all commercial goods (including the service traffic affected to the account of special funds) indicating the corresponding stations.

IV. Besides the collections of figures above, mentioned and appearing each year, there was published till 1905, a statement showing the traffic in all goods by quick and slow freight "on arrival" and "in transit".

Beginning with 1905, this publication was abolished for reasons of economy, only two copies of the statement being set up, one of these being kept by the administration of the system and the other presented to the ministry of finance.

The figures of the goods traffic " on arrival " and " in transit ", as well as those " at departure ", are prepared according to the classification of the goods by groups of names and by headings, the following information being furnished :

a) *Arrival.* — 1° Receiving station; 2° route; 3° sending lines; 4° sending stations, and 5° weight of goods (poods) " on arrival ", the corresponding figures being given per sending stations of the home system and other lines, together with the total arrivals per receiving station.

b) *Transit.* — 1° Sending lines : 2° points of junction with home system ; 3° receiving lines and 4° number of poods (weight of goods) " on arrival " and " at departure " from each line.

There is a question of renewing, to begin from 1909, the publication of returns of figures " on arrival " and " in transit ", in the style of the collection " on departure " and " in transit ".

On the basis of the statistical data above set forth and transmitted by the managements of each system, together with the supplementary information furnished by the latter at the will of the ministry of finance, the latter publishes every year the following statistical reports :

A. — *Passenger traffic.*

B. Figures issued by the ministry of finance. *a*) Annual publications.

Three collections of figures deal with passengers and their luggage. The first contains the figures " at departure ", the second those " on arrival " and " in transit ", and the third the total passenger returns for the financial year.

Each collection contains the corresponding data consigned to special tables, as follows :

1. Data of each itinerary, followed by the number of journeys according to classes of ticket and fares.

2. Abstract of stations with totals of passengers at ordinary and suburban rates.

3. Principal points of departure of passengers (ordinary suburban rates) exceeding 100,000 journeys per annum.

4. Classification of departure totals of each line per zone at ordinary fares.

5. Ditto at suburban fares.

6. Classification of passenger mileages per zone and average mileages at ordinary fares.

7. Ditto at the suburban rate.

8. Classification of receipts (in roubles) from passenger traffic per zone and at ordinary fares.

9. Ditto at the suburban rate.

10. Classification of the departure totals according to category of suburban service tickets, with an indication of the number of passengers and the receipts.

11. Weight of luggage and parcels dispatched.

12. Classification per zone of journeys effected at ordinary fares " on departure " from the most important points, starting from 100,000 journeys.

13. Percentages of seats available and occupied at ordinary and suburban fares for ten consecutive years.

14. Costs of transport by railway : *a*) totals for the whole system in millions of roubles; *b*) ditto per verst of length; *c*) per unit of mileage (passenger-versts and pood-versts)

15. Statement of the number of passengers and the receipts for each section of

the system between two stations of the suburban service.

16. Figures showing supplementary receipts for celerity, numbered seats and certain facilities upon the Russian system.

B. — *Goods traffic.*

This group of figures comprises data relative to the principal goods classed in forty-eight annual official reports. Three of the reports are devoted to the traffic in cereals, one includes general data of the traffic in all goods of the 1st and 2nd categories, and one contains the general totals of all goods traffic.

The statistical data of these official reports are grouped in tables as follows :

1. The most important stations and lines " at departure " and " on arrival ".

2. Distribution of the traffic per forwarding and receiving lines.

3. Statistics " at departure " for each line, with elimination of the departures from foreign lines, from the Russian maritime ports and from the ports of the Volga.

4. Statistics " on arrival " for each line and indicating the arrivals by foreign lines, from the Russian maritime ports and from the ports of the Volga.

The preface to each official report indicates the general totals of the corresponding traffic for the financial year and for the five years preceding.

Triennial publications.

Independently of the three collections of figures dealing with the passenger traffic and the forty-eight articles of goods, the ministry of finance issues periodical statements, spread ever three consecutive years, relative to the goods traffic.

These collections of figures, to the number of twenty, contain statistical data " at departure " and " on arrival " of goods of lesser importance, forming part of the official classification. The grouping of the data of these triennial statements is similar to that published each year.

C. Statistics published by the ministry of ways of communication.

But we have not yet recorded all the official traffic statistics.

The ministry of ways of communication also concerns itself with goods-traffic statistics, and issues an annual statement in accordance with the following programme :

1. Consignments and arrivals of cereals and other principal goods by slow freight per station.

2. Consignments and arrivals of the whole of the goods by slow freight per station, and their mileages between the consecutive stations according to the direction of the traffic (up and down).

3. Analysis of dispatch and arrival of principal goods and of total goods by slow freight according to mode of transport and railway mileages.

Unit statistics.

e) **Unit statistics as applied to volume of traffic carried, traffic earnings and utilization of rolling stock.** — The use of statistical units is widely spread over the Russian system, the very earliest railways having employed the length of the track and the mileages of trains and rolling stock as a measure of the operations effected. Subsequently there were added data as to the number of units of traffic and several others, a complete enumeration of which will be found in table X drawn up by the commission of 1884. (Data relative to traffic, receipts and mileages of rolling stock.)

Train-versts.

Table X contains the following particulars regarding train-versts :

General mileages of all trains, mileages of fast and ordinary trains, including :

a) *Special :* imperial trains; private trains; service trains;

b) *Regular :* express trains; mail and passenger trains; mixed trains; military trains; optional trains (passenger).

Mileages of slow-freight trains, including :

Goods trains; military trains; service trains.

After the fashion adopted on the British colonial system, the traffic earnings are brought into relationship with the corresponding mileages of fast, ordinary and slow trains, and with the total train mileages; but the calculation of the scale of fares could not be based solely upon such data : account has to be taken not only of the passenger and goods mileages, but also of their classification according to the relative nature of the traffic, the average distance, the direction of the traffic, and many other considerations, too numerous to be set forth in this outline of the practice.

Passenger-versts and pood-versts.

The same table (X) contains the following data concerning units of traffic mileages :

Total mileages of passengers.
Total service mileages.
Total mileages of luggage.
Total mileages of parcels.
Total traffic mileages per piece.
Total mileages of animals.
Total mileages of goods by slow freight; up traffic; down traffic.
Total traffic mileages.
Total mileages of animals.
Total service mileages.

These particulars are supplemented by an indication of the average distance covered, and the receipts per unit distance. They are further divided according to the classification of the objects conveyed, but no account is taken of them in the general conclusions of table X, to which are referred :

The mileage of the tare (weight) of stock employed, divided into :

Mileage of the tare of locomotives and tenders;

Mileage of the tare of vehicles (carriages and wagons), showing the tare related to the mileage unit of each train and of 10,000 vehicles.

The general conclusions of this table are presented in the following fashion :

Average load of each carriage axle (number of passengers).

Ratio of the average number of available and occupied seats to each carriage axle.

Average number of passengers in each train.

Average load of each wagon axle (number of poods).

Average number of poods in each goods train.

Ratio of the effective average load of each wagon axle to the transport capacity of the corresponding stock.

Ratios of the total mileages of wagons loaded and empty.

Gross mileage of the whole rolling stock and of the whole traffic by quick and slow freight.

With regard to the latter figure, it is to be regretted that a distinction has not

been introduced between ordinary and slow trains.

Zone tistics.

We have already referred to zone traffic statistics in our statement concerning the statistics of the volume and nature of traffic.

verage aul.

The figures relating to the average distance hauled are given in table X independently of the zone statistics, in connection with the statistics of the volume and nature of the traffic (see above).

Like those of the British colonial system, the Russian statistics also give the earnings for passengers and freight per verst of line operated.

Train oads.

Passing next to the consideration of the figures relating to the utilization of rolling stock, it should be at once understood that this is a question the importance of which is well understood by the managers and other heads of the Russian system. The question has, in fact, been before them since 1884, since the commission previously mentioned then occupied itself with it, drafting an abstract of wagon mileages per *month* and per *direction* of traffic. It was this commission, also, which added to the conclusions of table X the reference to the average load of each carriage axle as well as each wagon axle, without, however, appropriating them to the different *sections* of lines or to the *months* of the traffic.

In spite of the plethora of statistical data, with regard to mileage of stock and mileage of traffic alike, there is too sensible a difference in the organization of their elements to render it possible to relate them to each other. The fact is that the parallel data, by defect of agreement as much with regard to the sections of the system as to the periods of the year (months) and the directions of the traffic (up and down), scarcely lend themselves to proper conclusions. As this question is still under consideration, we confine ourselves to indicating the points which may be regarded as settled. There is first of all the principle of the parallelism or uniformity of the classification of mileages, as much for rolling stock as for traffic. The ideal would no doubt be found in the study of the work actually accomplished by each kind of stock which has served for the transport of such a class of passengers or kind of goods, in such a month of the year, upon such a section of the system, in such a direction of traffic.

Unfortunately, so detailed a comparison between mileages, stock and traffic would involve an increase of work and expense out of all proportion to the results to be obtained. The question, then, is to find a line of demarcation with a view to deciding the question in as liberal a fashion as the circumstances permit. As Russia transports a great quantity of cereals and other non-manufactured articles, it is clear that fluctuations of traffic must be very frequent, and that the period for the registration of corresponding data ought not to exceed one month. Statistics of the utilization of stock should, then, be monthly. As to the sections of the system, the point is more difficult to settle, in view to the very great difference in the bulk of traffic per unit of length. The simplest plan would be to bring together the statistical elements (mileages of stock and mileages of traffic) for each portion of

the system situated between two neighbouring stations and in the two directions of traffic separately, subject to combining the product of these sections according to the varying needs of the service. We are, then, absolutely in agreement with Sir Thomas Rees Price when he says " that the value of the information as an aid to operation would be much greater *were the figures given* separately *for each section, for up and down traffic*, and for traffic *between specially important points on the system*". This is precisely what we ourselves set out to do (since 1884) in carrying forward all these data to each month of the financial year, with a classification of the traffic and stock employed in more or less detail, according to the requirements of the service. A monthly analysis is so much the more urgent that the costs of working vary a good deal by reason of the degree of utilization of stock, that our budgetary legislation admits of many variable credits (according to the units of traffic), and that we are obliged to draw up monthly statements of credits in view of a periodical control of the execution of the budget, organized upon all the State systems and those of the companies.

Efficiency and utilization of locomotives and rolling stock.

Statistics of train mileages are kept by all the Russian railways, and show separately :

Mileages of commercial trains :

Fast trains : Imperial trains; express trains; postal and passenger trains; mixed trains; special trains; total fast-train mileages.

Slow trains : goods trains; service trains; total slow-train mileages.

Military : troop trains; hospital trains; supply trains (equipment, stores, etc.); total military mileages.

Administration : fuel trains; building-material trains; ballast trains; trains carrying earth and snow; total administrative mileages; general total of mileages of trains of all descriptions.

As to locomotive mileages, these are classed according to the following categories :

I. *Remunerated :* passenger trains and mixed trains (fast and ordinary); goods trains (slow freight); military trains; service trains; double-headed trains.

II. *Non-remunerated :* light; reserve; station service.

The shunting mileages (station service) are calculated upon basis of a uniform speed of 5 versts (3·3 miles) per hour.

The mileage figures above set forth are recorded monthly and show the totals of four successive years, with an indication of the average composition of each of the three great categories (number of cars and number of axles) together with the total average mileage per day and per unit lenght (verst) of the system. The proportions per cent of the different categories of train mileage are also mentioned. A special table shows the locomotive mileages for each series (type) during four successive years, subdividing them into mileage remunerated, total and average, separately for locomotives actually utilized and for the totality of the inventory, and at the same time indicating the maximum mileage of each locomotive forming part of each given series.

Finally, a brief accqunt is given, for each month of the financial year and the total

of four successive years, of the mileages of the locomotives per section and per month, for each of the categories of trains mentioned above.

But the gross ton-miles (pood-versts) hauled per locomotive and per type are not obtained, owing to a lack of unanimity in the organization of the traffic statistics, and all one is able to do is to calculate (for the whole financial year) the average load of each category of train, alike as regards cars, axles and units of traffic, taking no account of sections of system, months, etc.

There is also kept in the case of each locomotive, mileage statistics giving the dates of the reports presented by each engine-driver at the time of his return to the sheds, during the whole period the locomotive remains in service.

ileage oads.

We have already indicated the theoretical value attached by the Russian railways to exact data regarding the utilization of passenger and goods cars alike.

Unfortunately, as we have just pointed out, for lack of a proper agreement between the data, it is not practicable to furnish statistics per month, per section, per direction of traffic, and per kind of stock employed and traffic effected. With regard to the corresponding figures, which are obtained for the whole system and for the whole year, they are of very slight value from the statistical point of view since no account is ever taken of the bad or good utilization of the stock, and one cannot, therefore, derive any information from them.

We are, then, entirely in agreement with the reporter as to the necessity of co-ordinating these data henceforth in a fashion much more precise than is the case today.

As regards the utilization of carriages of different classes and the average load for each class taken separately, the figures are set up for each financial year, since the carriage mileages are recorded per month and in special abstracts, even for each train taken separately, that is to say in the most detailed fashion possible. It is regrettable that these figures, transferred by us to the temporary statistics, should not be reproduced in the tables inserted in the annual returns.

As to the utilization of goods wagons, the annual returns set forth the car mileage separately for covered stock, open trucks, fuel trucks, ballast trucks, and tank trucks for the transport of naphtha ; not only for the whole system and per month, but also by series of trains : passenger, goods, military and service.

But these data are not brought into comparison, as we have just pointed out, with those of the traffic mileage, except in their totals for an entire year and for the whole system.

f) **Statistics of cost of operation.** — Although we share the opinion of the reporter as to the importance of statistics of expenditure, classed according to the operations and not according to departments or administrative services, we do not think it possible to change the classification of the budget of expenditure in accordance with these principles, seeing that this portion of the budget represents an instrument of government, the service chiefs acting as directors of expenditure. It is, however, through the departmental classification that so much dif-

ficulty arises in rendering account of the costs of the various traffic operations, whereas it is an easy matter to fix the corresponding receipts (or, at least, the average receipts), which are classed by operations and not by departments.

Il is true that the budget of expenditure, classed by departments, includes also a considerable number of subdivisions corresponding to the various items of reveue; but these particulars are scattered about among the different headings, sections, etc. It would be necessary, therefore, as a preliminary step to bring them together, which would involve extra work and appreciable loss of time, to say nothing of the differences of opinion as to the method of co-ordinating them (see annex III to our report on the question of accounts).

The task of settling questions which relate to good management of railways is a difficult one. The Russian State system has just had painful experience of that fact. With a doubtful establishment account, and with the liabilities in the balance-sheet surcharged with figures merely estimated and to a considerable extent of a fictitious value, and burdened, moreover, with the cost of a great strategic line like that of Eastern Asia, the State system will not so soon be able, in view of the special and political character of its operations, to cover the capital charges of original establishment and subsequent improvements, or often even the working expenses.

The system has nevertheless rendered the State immense service, during recent years, in the exportation of cereals and in considerable transports of soldiers and emigrants, despite innumerable difficulties and under the pressure of invariably hostile criticism.

These service complications place us in a position to appreciate all that is true in the opinion expressed by Sir Thomas Rees Price that an increase of expenditure (even if accompanied by a decrease in the train mileage) does not necessarily imply bad working. It is therefore of the highest importance that the accounts should be presented in a form easy to grasp, and that the unit statistics should be appropriated to their proper end and be sufficiently complete to admit of correct deductions being arrived at without too much difficulty. From this point of view, we accept unhesitatingly a classification of expenditure into :

1. Maintenance of way and works;
2. Maintenance of equipment (locomotives and rolling stock);
3. Transportation, *i. e.* running expenses;
4. Traffic, properly so-called;
5. General charges, which are of a universal character; although not corresponding exactly with the different departments of the service (see annex III to our paper on the question of accounts).

In accordance with the methods indicated by Sir Thomas Rees Price, we also reduce the expenditure to averages per unit, such as the verst of lines open, ditto per verst of single main line, 100 train-versts, 1,000 locomotive-versts, 10,000 axle-versts of passenger stock, ditto of goods stock, ditto total, 1,000 passenger-versts, 1,000 pood-versts, in proportions per cent of the earnings, ditto of the total expenditure without counting the units of a more particular order, such as the num-

ber of stations and yards, the site areas of buildings, yards, etc.

Statistics of staff employed.

Much attention is given in Russia to statistics of the railway staff. The returns include a table giving a very detailed enumeration, and for each department or service separately in respect of the different grades, the effective force of the staff employed and the remuneration for each financial year, a comparison being made with the budget estimates and not with those of the previous period, which would be of much greater utility. Comparisons between the different periods and with other railways are therefore always practicable, although involving a rather considerable loss of time.

There is also a general summing-up of the effective force of the staff and its remuneration in the general statistical statement of the ministry of ways of communications (annex I to the present memorandum), greatly facilitating a comparison of the condition of the staff upon the various systems.

Sectional figures of expenditure.

Although highly appreciating the practical value of monthly statistics according to sections, as an element of emulation between staffs directing certain portions of the system, we have nothing in any way comparing with the model given in the annex to the report of Sir Thomas Rees Price. It is only with great difficulty that we have got to the point of compiling monthly data for each system, and even now in many respects the figures are open to the charge of being merely provisional. As a consequence of the very complicated method of liquidation of accounts under our extremely bureaucratic and red-tape system of control (see our report on the question of accounts, in the seventh session) definitive figures cannot be complied without the loss of a good deal of time.

We possess, however, nearly all the elements required for the drawing-up of tables by sections, and have no objection to bring forward against the method of apportionment of expenditure among the different divisions described by the reporter.

Division of expenses between passenger and goods services. General remarks.

There is general agreement, in Russia, as to the utility of the division of expenditure between the passenger and goods services, and this division, in accordance with a form approved by the ministry of ways of communication, has been made regularly since 1895 in table IX of the official record of railway statistics of the Empire (State and companies) although the general practice takes little enough account of this great work, the bases of which were established in former days, after a minute enquiry, by Mr. Gortschakoff, engineer of ways of communication, member of the commission of 1884, and today inspector-general of the Russian railways.

As Sir Thomas Rees Price remarks, the question of apportioning expenditure between the passenger and goods services is of a controversial character, and the method applied upon the various systems of the world do not differ in too pronounced a fashion.

We give a detailed idea of the official Russian method of apportionment in table IX (see annex I to our memorandum). Without entering into further detail, let us confine ourselves to reproducing some observations of the late

Mr. Saloff, former president of the higher technical council of the ministry of ways of communication, an author whose great competence will not be disputed by any of those who have the good fortune to be brought into contact with this rare and lofty spirit. This is the manner in which Mr. Saloff expressed himself:

" The statistical record of the ministry of ways of communication establishes a division of expenditure between two categories of trains, one of which comprises goods trains and service trains, and the other the whole of the remaining trains. The expenses of the first category are reduced to pood-versts, those of the second category to passenger-versts, the mileages of luggage and parcels being reduced to passenger-versts in the proportion of the revenue. This method of calculation cannot be held as rational, seeing that : 1° the reduction of luggage and parcels carried by fast train into pood-versts in proportion to the receipts does not correspond with the costs of transport which differ greatly; 2° the fast and ordinary trains also include luggage-vans and special vans the expenses of which ought not to burden the costs of passenger traffic; 3° the passengers carried on service are not counted. But one can obtain results almost as precise, and with much less complication, by dividing up the sum total of the working expenses according to the axle-mileage of the vehicles, employing certain coefficients for the passenger stock and the goods stock."

It results from the calculations made by Mr. Saloff that the cost of three passenger-carriage axles corresponds almost exactly with the cost of four goods-wagon axles. These approximate figures are confirmed by a much more detailed analysis of the corresponding expenses.

After these declarations of a general character, we pass to an examination of the working of the different branches of the service, still following the line traced by the honourable reporter.

But before entering fully into the matter, and to avoid all confusion in the examination of so complex a question, do not let it be forgotten that the point under consideration is the distribution of expenses based upon the classification of headings of the budget of expenditure.

These headings, in accordance with the scheme of 1884, are 322 in number. Conformably with the regulations concerning to annual returns of 1884, each credit (or item of expenditure) should be divided into costs of administration, costs of labour, and costs of stock, including spares, which would bring the number of elements up to a minimum number of 966, As for each article it is necessary, at least, to give the number, the kind, and the net cost, we reach already a classification of no less than 2,898 constitutive elements. Since each element, again, can be divided according to its nature, into an infinite number of others (each such product comprising dozens of categories of labour and materials), we arrive at an extraordinary complication in endeavouring to analyse each of the 322 headings of the budget of expenditure.

Accordingly the commission of 1884 limited itself to impressing upon the railways the duty of furnishing in their reports and accounts *explanations reproducing full details of the composition of each item of revenue and expenditure* (see our report on accounts to the seventh

session), leaving to the general association of railways or to the managements of the systems the creation of the corresponding model forms. We have already pointed out to what this free way of dealing with the matter led. Desirous at all costs of putting an end to the existing state of affairs, a commission which has just been appointed for the establishment of a new classification of expenses and their auditing has stopped at the setting-up of a special table for each of the 148 items of the new classification. It is from this work that we borrow the elements necessary for a comparison of our organization with the data of the reporter.

Main-enance of way, orks and tations.

Maintenance of way, works and stations. — These costs of maintenance are worked out per verst of the length of the system and per verst of main line (single), without indication whether the sidings are included. The maintenance of the rails is related, further, to the gross pood-verst. There is also given the percentage of the costs of maintenance to the sum total of the expenditure of the service of way and works. With regard to the special data concerning the items set out under this heading by the reporter (ballast, sleepers, rails, relaying, extraordinary expenditure for maintenance, bridges, stations and buildings) we do not bring these specially under the notice of the reader, since their distribution is, to all intents and purposes, the same as for the remainder of the items of the budget.

Let us content ourselves with indicating that there is always included a comparison between five successive years, which renders it sufficiently obvious if the figures appreciably differ from the average. Should such be the case, detailled explanations have to be furnished.

Maintenance of rolling stock.

Maintenance of locomotives. — The costs are worked out per total locomotive-verst without any distinction being made between fast, ordinary and slow services. Statistics are always kept of the mileage effected by each locomotive per month, together with the costs for repairs of each locomotive, and periodical or temporary statistics, of which we have spoken earlier, as to the number of locomotives partly or generally repaired, with an indication according to class of the repairs effected.

At the same time, the expenses are divided into costs of repair of locomotives and repair of tenders, there being shown, on the one hand, the costs of locomotives in regard to boilers, frames, gear and other parts, painting; and, on the other hand, the costs of repair of tenders, of water-tanks, etc., and painting.

Passenger stock. Maintenance. — The costs are worked out per carriage-mile and per axle-mile.

As in the case of locomotives, periodical statistics of repairs are kept, such repairs being classed by categories.

Goods stock. Maintenance. — The costs are worked out per axle-mile of wagon, and statistics of repairs are kept by categories or types of wagons when these types are differentiated in any marked fashion.

Traction expenses. — The traction expenses are worked out per locomotive-mile and car axle-mile and the statistics of such expenses are kept in a very detailed manner and, taken as a whole in confor-

mity with the indications given by the reporter.

Traffic expenses.

Traffic expenses. — The traffic expenses are divided into train expenses and station expenses.

The expenses of the first category are worked out per train-mile of the fast, ordinary and slow trains, whilst the station expenses are related to the length of the line, an obviously very summary method.

As regards the costs of the handling of luggage and goods by the stations, they are worked out per pood of goods dealt with.

Very detailed statistics give, for the work of each station and for the financial year, the number of trains, carriages and wagons received, dispatched, and exchanged, with neighbouring lines; the number of poods loaded and unloaded; the number of passenger tickets issued; the number of luggage-tickets and waybills for parcels and goods; the number of telegraphic messages exchanged; the receipts cashed; the hours and mileages of shunting locomotives and their relation to the wagons and poods received and forwarded.

General and other charges.

General and other charges. — The principles governing the general charges upon the Russian systems are in every respect similar to those indicated by the reporter. We have therefore no observations to offer on this subject.

Stores department.

g) **Statistics relating to indirect and subsidiary services. — Indirect services.** — The service of furnishing supplies for the Russian railways is strictly centralized in a special department or service (that of the stores), even in the case where certain issues of stores are made directly by the consuming services (notably by that of the way and works). As all the documents are centralized in the stores service, the latter prepares every month an inventory in the form given in annex IX to our report on the question of accounts. It is compared with the figures of two successive years, and particulars are given of the surplus stock of each category of stores, their receipt and issue during the financial year, the deliveries made to each consuming service : the whole according to category and value (roubles), care being taken to mention the proportion per cent relatively to the material in stock. The warehousing expenses are charged to the consuming services.

Work-shops.

The workshops of the Russian railways are placed under the direction of the chief engineer of the locomotive department, and the organization and working alike correspond exactly to that of the British colonial system. Several statistical tables relate to this service. There is, first of all, table VII, drawn up by the commission of 1884, the data for which are furnished by each workshop separately. Then comes a very detailled enumeration of all the works executed during the financial year, with information as to the object, quantity, nature and costs of annotation, labour and materials (including also the spares, etc.).

It goes without saying that the whole of these details do not appear in the report and accounts for the financial year, although they are to be found in the

workshop books, where they are recorded in the minutest possible fashion.

Subsidiary services. — The subsidiary services are practically identical with those enumerated by the reporter, and the statistics are not of any particular interest. All the operations relating to lifts, town offices, etc., are a part of the subsidiary services.

aff, social onditions.

h) **Other miscellaneous statistics.** — Independently of tables showing the number and remuneration, as well as the average pay of the staff in the different services, statistics of the social conditions of the staff are kept relating specially (and exclusively) to pension, savings-bank and relief funds, etc. Particulars of rather exceptional interest, in relation to sex, age, civil condition, length of service, causes of changes, average renumeration, etc., are recorded.

Other social statistics.

The Russian railways are bound to furnish reports on all accidents, even those of the slightest importance. A summary of such reports appears in tables X and XI of the statistical record of the ministry of ways of communication. These statistics respond exactly to the wishes expressed by the reporter.

THIRD PART.

Uniform classification of working expenses.

The Russian railway systems (State and companies alike) make use of a form of classification of expenses imposed upon them by the government in accordance with a scheme elaborated by the commission of 1884. As we have inserted this classification in annex III to our report on Russian railway accounts, we limit ourselves to reproducing the principal sections, in the order of classification set forth in the comparative table given by Sir Thomas Rees Price (1).

(1) See *Bulletin of the Railway Congress*, number of December, 1909, p. 1604.

Section III. — *Maintenance of way and works; supervision, maintenance and repairs.*

This section contains the three following divisions :

Division 1. — Costs of central service of way and works.

Division 2. — Supervision of way and of constructive works, etc.; their maintenance and repair.

Division 3. — Supervision of buildings, their maintenance and repair.

This section corresponds exactly to the service of way of the French system.

SECTION V. — *Traction expenses : maintenance and repair of rolling stock.*

This section contains seven divisions, *viz.* :

Division 1. — Costs of central traction service.

Division 2. — Traction.

Division 3. — Maintenance of carriages and wagons.

Division 4. — Maintenance of central workshops attached to locomotive sheds for the repair of rolling stock.

Division 5. — Renewal and repair of locomotives and tenders.

Division 6. — Renewal and repair of carriages and wagons.

Division 7. — Hire of rolling stock.

This section corresponds exactly to the service of equipment (locomotives and rolling stock) and traction (*i. e.*, running expenses) of the French system.

SECTION IV. — *Service of traffic and telegraphs.*

This section contains four divisions, *viz.* :

Division 1. — Costs of central service of traffic and telegraphs.

Division 2. — Service of stations and yards.

Division 3. — Service of trains.

Division 4. — Service of telegraphs and telephones.

This section corresponds fairly closely with the traffic service of the French system, except as regards the commercial service of receipts which, in Russia, are included in the general expenses (section I).

SECTION I. — *Central administration (or board of administration). Commercial service, service of receipts and general expenses.*

This section comprises three divisions, *viz.* :

Division 1. — Costs of central administration and commercial service.

Division 2. — Costs of service of receipts.

Division 3. — General expenses.

SECTION II. — *Management of each system; medical service and stores.*

This section contains four divisions, *viz.* :

Division 1. — Costs of manager, his assistants and office of management.

Division 2. — Costs of medical service.

Division 3. — Costs of stores service.

Division 4. — General costs of the management services of each system.

Sections I and II correspond fairly closely with the general administration of the French system.

An analysis of this classification shows that it includes, at the same time, the whole of the particulars furnished by the American classification, *viz.* :

1. The maintenance of the track and its appurtenances and of the buildings utilized in connection with its operation (section III).

2. The maintenance of the locomotives and rolling stock used for the conveyance of traffic (section V, divisions 4, 5 and 6).

3. Expenditure incurred in obtaining traffic and in affording information as to the facilities given by lines for the conveyance of traffic (section I, division 1, commercial service).

4. Expenditure directly or indirectly connected with the actual conveyance of traffic : such as cost of operation of trains and stations (section IV, divisions 2 and 3; section V, division 2).

5. General expenses (sections I and II).

We are of opinion that this classification would readily lend itself to the plan proposed by Sir Thomas Rees Price, *viz.* :

1. Maintenance of way, works and structures.
2. Maintenance of equipment.
3. Transportation and traffic expenses :
   a) Running expenses and supplies (locomotives and vehicles).
   b) Station and other traffic staff.
   c) Cost of obtaining traffic, etc.
4. General charges.

We are equally disposed to believe that a uniform method of classification would be applicable to all the railways, by the adoption for lines of lesser importance of the classification by main heads or sections, and for the others that by subdivisions, sub-heads, etc. We may further remark that the classification of expenses imposed in Russia upon all railways (to the total of 323 index numbers), without account being taken of their relative commercial importance, appears excessive and will probably be reduced by at least one-half.

Treatment of expenditure on indirect services.

We have no objection to raise, as far as the subsidiary services are concerned, after what we have said as to the position they occupy in our classification.

Other matters affecting working expenditure.

a) *Real estate.*

Any profit (or loss) on *real estate* account is carried to the revenue account (section III : receipts pertaining to financial and supplementary operations or to expense account; section VIII : expenses pertaining to financial of supplementary operations).

b) *Depreciation of capital assets.*

The commission of 1884 (p. 195, line 3 of our report on the question of accounts) investigated the question of the liquidation of the costs of renewal of rails, plant and rolling stock in the proportion of the mileages effected during the financial year, as well as the method of charging the corresponding expenses.

Although provisions in conformity with its views were introduced in the form of special regulations, they did not receive the sanction of the government, the latter fearing that the effect of the allowance for depreciation would be prejudicial to the guarantee of interest of the State.

c) *Capital expenditure and expenditure for betterment.*

The original establishment expenses are carried to the balance-sheet of the under-

taking, whilst the expenses for betterment are carried to a special account, the classification of which we have given in annex V to our report on accounts. It is of the highest importance that such expenses (except those of a very minor character) should be kept strictly separate from the working expenses.

FOURTH PART.

Conclusions.

We fully share the opinion of the honourable reporter with regard to the classification of the permanent statistics (having special reference to the returns for each financial year) and of the temporary tables or statements, as well as the necessity for bringing about some sort of uniformity in the methods of railway accounting, for effecting, at any rate, *the standardizing of the principal statistical returns and the establishment of a recognized standard classification of statistical data.*

We are entirely in accord with the views of the reporter as to the incalculable advantages which should accrue, not only to the railways of the world but also to the governments, the press and the public at large, from the adoption of a standard classification of budget (and balance-sheet).

Although the labours of the International congress on statistics convoked at The Hague in 1881, have remained in suspense since the publication of data concerning the system of European railways for 1882, we are glad to think that this question, taken up again *after postponement for nearly thirty years*, will be settled in a satisfactory manner. It will suffice for us to recall, in connection with this prognostic, the ever-celebrated saying of Napoleon I: "*If it is possible, it is done; if impossible, it shall be done.*"

FIFTH PART.

Annexes.

I. — General statistics of the ministry of ways of communication of Russia (tables I, II, III, IV, V, VI, VII, VIII, IX, X, XI).

II. — Statistical annexes to the returns for each financial year, introduced by the commission of 1884 (tables I, II, III, IV, V, VI, VII, VIII, IX, X).

III. — Scheme of periodical statistical statements, of a temporary character, now in preparation.

ANNEX I

General statistics of the ministry of ways of communication of Russia

(Tables I to XI.)

Table I-A. — **Financial position of railways operated by the State at the end of financial year.**

1	2	3	4	5	6	7	8	9	10	11	12	13	14
Index number.	DESIGNATION OF LINE.	Length of lines at end of financial year.	Date of redemption of lines (year, month and day).	Original capital, and subsequent additions.				Other expenditure since date of opening				Total first-establishment expenses.	
				Bonds converted by the government (consols).				upon the State Treasury.			upon the working receipts and other funds.	Total	By verst of length.
				Nominal amount.	Annual costs of guarantee of interest and amortization.			Nominal sum.	Interest and amortization expenses for the financial year.			Roubles (credit).	
					For the whole capital indicated in column 5, for the year.		Total amount for the financial year.						
					Total.	Per cent.			Total.	Per cent.			
		Versts.		Roubles.		Per cent.	Roubles.	Roubles.		Per cent.	Roubles.	Roubles.

ANNEX II

Statistical annexes to the returns for each financial year introduced by the commission of 1884.

(Tables I to XIV.)

Table I. — General particulars of the line.

1. Date of the concession or other documents of title, and subsequent alterations made in the original acts (with indication of the articles modified). 2. Date of the opening of line (per sections). 3. Length of line operated. 4. Length of time scales of rates applied. 5. Virtual length : *a*) up ; *b*) down. 6. Commencement and end of concession (if the conditions differ according to sections) for each section separately. 7. Term of redemption according to concession.

Table II. — Total length of lines.

Designation : I. Length of running line. II. Length of branch lines. III. Length of service branch lines. IV. Length of branch lines belonging to private persons.	Length of single track.	Including :								
		running line			sidings of all kinds					
		total	that is to say :		total		that is to say :		
			single line.	double line.	versts.	ratio to length of main lines.	sidings.	reserve lines.	locomotive lines.
	Versts.						Versts.		

Table III. — Data regarding rails and sleepers.

I. On main lines. II. On commercial branch-lines. III. On service lines.	Kind of rails, their type and date of laying.	Rails.								Sleepers.							
		Number of versts of rails :								Kind of sleepers.	Number of sleepers :						
		on main lines				on sidings					on main lines				on sidings		
		first.	second.	total.	total per type.	sidings.	others.	total.	total per type.		first.	second.	total.	total per type.	sidings.	others.	total.	total per type.

Table IV. — **Data regarding permanent way, constructive works, crossings, and accessories of line.**

1			2		3	4	5						6						7		8		9	10		
Number of administrative sections and their respective lengths.			Length of track between stations (versts).		Description of portions of line situated between the stations.	Length of main lines on the flat.	Length of up gradients :						Length of down gradients :						Maximum length and height of up gradients.		Maximum length and height of down gradients.		Length of flats.	Length of curves.		
Permanent way service.	Traffic service.	Traction (locomotive) service.	Actual distance between centres of stations.	Length of time scales of rates applied.			more than 2 and up to 4 per mil.	more than 4 and up to 6 per mil.	more than 6 and up to 8 per mil.	more than 8 and up to 10 per mil	more than 10 per mil : that is to say : more than 125 per mil, and so on.		more than 2 and up to 4 per mil.	more than 4 and up to 6 per mil.	more than 6 and up to 8 per mil.	more than 8 and up to 10 per mil.	more than 10 per mil : that is to say : more than 125 per mil, and so on.		Height.	Length.	Height.	Length.		Radius : 600 sagenes and more.	Radius : less than 600 sagenes and more than 300 sagenes.	Radius : 300 and more than 150 sagenes.
							Versts.						Versts.						Sagenes.					Versts.		

Table IV (continued). — **Data regarding permanent way, constructive works, crossings, and accessories of line.**

10		11		12				13				14		15				16		17		18				19	
Length of curves.		Maximum length of a curve of radius : 300 sagenes and less.		Virtual length and coefficient.				Length of embankments and cuttings.				Tunnels.		Surface of formation level.				Length of side ditches.		Culverts in wood.		Culverts in iron :				Culverts in stone :	
Radius : 150 sagenes and less : that is to say :				Up.		Down.		Embankments :		Cuttings :				Embankments :		Cuttings :						diameter : 0·3 sagene.		diameter 0·5 sagene.		opening : 0·30 sagene.	
150 sagenes.	and so on.	length.	radius	Virtual length.	Coefficient.	Virtual length.	Coefficient.	height to 1 sagene.	height of more than 1 sagene.	depth to 1 sagene.	depth of more than 1 sagene.	Number.	Total length in sagenes.	covered with stones.	covered with fascine-work and mixed	covered with stones.	covered with fascine-work and mixed	earth-ditches.	other.	Number.	Length in sagenes.	Number.	Length in sagenes.	Number.	Length in sagenes.	Number.	Length in sagenes.
Versts.		Sagenes.						Versts.						Square sagenes.				Sagenes.									

Table IV (continued). — **Data regarding the permanent way, constructive works, crossings, and accessories of line.**

19	20					21										22									
Stone drains.	Wooden bridges.					Culverts with opening up to 2 sagenes (included) upon stone or metal supports.										Bridges with span exceeding 2 sagenes upon stone or metallic supports.									
Opening 0·50 sagene:	Height of supports up to 3 sagenes:			Height of supports of more than 3 sagenes:		Wooden beams:						Metal girders:				Single part:									
						a) height of supports up to 2 sagenes:			*b*) height of supports of more than 2 sagenes:			*a*) height of supports up to 2 sagenes:			*b*) height of supports of more than 2 sagenes	*a*) height of supports up to 3 sagenes:			*b*) height of supports of 3 to 5 sagenes:			*c*) height of supports of more than 5 sagenes:		
number.	number.	total length of crest.	including compound beams.	number.	total length of crest.	including compound beams.	span: 0·00 sagene	span: 0·00 sagene.	and so on.	span: 0·00 sagene.	span: 0·00 sagene.	and so on.	span: 0·00 sagene.	span: 0·00 sagene.	and so on.	span: 0·00 sagene.	span: 0·00 sagene.	and so on.	span: 0·00 sagene.	span: 0·00 sagene.	and so on.	span: 0·00 sagene.	span: 0·00 sagene.	and so on.
and so on.																									

Table IV (continued). — **Data regarding permanent way, constructive works, crossings, and accessories of line.**

22						23		24			25											
Bridges with spans exceeding 2 sagenes, upon stone or metal supports.						Other constructive works.		Crossings:			Accessories of line:											
Multiple parts:										Area:			fixed line signals:									
position of bridge.	length of bridge.	span.	number of supports.	average height of support	height above level of water.	Designation of works.	Number.	number.	including non-guarded.	wood.	paving.	gradient boards.	indicators of limits of sections, districts, etc.	semaphore.	green disks.	bells.	blocks.	other signals.	length of snow screens.	length of quickset hedges.		
	Sagenes.			Sagenes.						Sagenes.		Number							Sagenes.			

Table V. — **Data regarding lands taken over, buildings and works of stations and permanent way.**

Index number.	DESIGNATION OF STATIONS AND THEIR CLASSES.	Lands taken over.	Height of platform.	Length of track : total.	Length of track : including sidings	Length of track : Sagenes.	INDICATION OF NATURE OF BUILDINGS AND WORKS.	Passenger buildings : with habitations.	Passenger buildings : without habitations.	Passenger platforms : corresponding with buildings	Passenger platforms : situated between the lines	Barriers on platforms.	Water-closets.	Lamp department	Goods platforms : covered.	Goods platforms : open.	Temporary arrangement for goods.	Goods sheds.	Goods offices.	Water-closets.	Weighing apparatus.	Arrangements for watchmen.	Arrangements for doorkeepers.

Table V (continued). — **Data regarding lands taken over, buildings and works of stations and permanent way.**

Habitations					Subsidiary installations near buildings :									Buildings of special character :								
pointsman's boxes : single.	pointsman's boxes : double.	barracks : single.	barracks : double.	other type	separate kitchens.	sheds.	refrigerators.	wells.	baths.	laundries.	water-closets.	pits.	other services.	fences.	churches.	schools.	hospitals.	locomotive sheds.	wagon sheds.	work-shops.	warehouses.	sheds for military installations.	cellars for inflammable goods	fire-engine depots.

Table V (continued). — **Data regarding lands taken over, buildings and works of stations and permanent way.**

Other buildings, with indication of their nature.	Area of court-yards and ways of access to stations, paved.	Telegraph.			Opticals signals.			Electric bells.	Station accessories.													
		Number of wires.	Number of apparatus :		Disks :		Semaphores.		Weigh-bridges :		Points.	Crossings, frogs.	Switch sleepers :		Triangles.	Swing-bridges.	Traver-sers :		Lifting apparatus.	Bars.	Ash pits.	Pointsman's boxes.	Block signal box.	Locking frame in signal tower.
			telegraphic.	telephonic.	green.	red.			open.	covered.			number.	sagenes.			locomotives	wagons.						

Table V (continued). — **Data regarding lands taken over, buildings and works of stations and permanent way.**

Buildings and apparatus for water-supply.																							
Water-cranes :		Capacity of reservoirs	Habitations near waterworks.	Watercranes.	Other habitations.	Springs :		Height.	Boilers	Engine power.	Description of apparatus for raising water.	Length of electric wire	Water pipes :						Taps and cocks :					
													suction.		com-pression.		Distribution.							
single.	double.					designation.	quantity of water per day.						Length.	Diameter.	Length.	Diameter.	Length.	Diameter.	supply.	washing.	sprinkling.	suction.	fire.	stop.

Table VI. — **Data relating to locomotives and tenders, and relative installations.**

Locomotives.															
CLASS OF LOCOMOTIVES.	Series.	Number.	Manufactory.	Date when put in service.	Cylinders.			Boilers.				Heating surface.			Maximum of steam pressure beyond one atmosphere.
					Diameter.	Piston stroke.	Position.	Diameter.	Length of tubes between tube plates.	Number of heating tubes.	External diameter of heating tubes.	Total.	Including: exterior of heating tubes.	Including: the combustion chamber.	
					Millimetres.			Millimetres.			Millimetres.	Square millimetres.			
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16

Table VI (continued). — **Data relative to locomotive and tenders, and relative installations.**

Locomotives.													Tenders					Number of locomotive sheds.	
Axles: Number.		Axles: Diameter of wheels:		Axles:	Weight:			Tractive effort according to formula.	Analysis of number of locomotives indicated in column 3 according to nature of fuel.				Axles:		Weight:				
Total.	Including driving.	coupled.	running-wheel.	Wheelbase.	without fuel or water.	with fuel and water.	per driving axle.		Nature of fuel.	Number of locomotives.	System of locomotives.	Number of locomotives.	number	diameter of wheels.	empty.	loaded.	Water capacity of tenders.	Total.	Ratio to number of locomotives. Per cent.
17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36

Table VII. — **Data regarding number of cars and relative installations.**

KIND OF CAR.	Series.	Manufactory.	Date when brought into service.	Number of cars: total.	Number of cars: including brake-vans.	Nature of brakes.	Number of axles of cars.	Average weight per vehicle.	Number of seats.	Capacity per wagon (poods).	Total: trucks.	Total: axles.	Total: seats.	Total: capacity.	Capacity of installations for coaching vehicles: total per car.	Capacity of installations for coaching vehicles: ratio to the total number of coaching vehicles.
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17

Table VIII. — **Data regarding number and plant of central and secondary workshops.**

DESIGNATION OF CENTRAL AND SECONDARY WORKSHOPS.	Area of covered installations for: repair of locomotives.	Area of covered installations for: repair of cars.	Area of covered installations for: mixed, for repair of locomotives and cars.	Number of places set apart in workshops for: repair of locomotives without tenders	Number of places set apart in workshops for: ratio to total number of locomotives.	Number of places set apart in workshops for: ratio to total number of cars.	Number of places set apart in workshops for: ratio to total number of cars.	Length of workshop and depot lines: Total.	Length of workshop and depot lines: including for repair of cars.	Capacity of all engines of workshops.	Number of fires and furnaces: permanent furnaces, number of fires.	Number of fires and furnaces: number of cupola furnaces.	Number of fires and furnaces: number of other furnaces.	Number of hammers.
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table VIII (continued). — **Data regarding number and plant of central and secondary workshops.**

Maximum number of casts per month.		Number of machine-tools for metal working:									Wooden-working machines.	Total:			Average number of artisans and workmen.	*Remarks.*
Cast iron.	Cast brass.	Total.	furnace for wheels of locomotives.	furnace for wheels of cars.	others.	drills.	planing-machines.	mortise machines.	screw-cutting machines.	others for metal		fitter's vices.	benches.	grind-stones.		
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32

Table IX. — **Data regarding maximum commercial transport capacity of line.**

Section number.	BY SECTIONS AND DIRECTIONS.	Maximum number of trains with reference												Transport capacity with reference	
		to the permanent way and other installations						to the water supply						effective force of rolling stock (cars).	effective force of stock for certain periods of heavy traffic (maximum).
		by direction						by direction							
		up.			down.			up.			down.				
		Kind of trains.	Number.	Speed.	Kind of trains.	Number.	Speed.	Kind of trains.	Number.	Speed.	Kind of trains.	Number.	Speed.		

Table X. — **Data regarding traffic, receipts and mileage of rolling stock.**

(Results of the working for four successive years and the budget anticipations for the financial year.)

I. — Passengers and transports at quick-freight tariffs and corresponding receipts.

1) Total receipts derived from special trains for the Imperial family, the government and private persons. 2) Number of passengers at fares of all kinds (remunerative). Including : 3) Number of through passengers. 4) Number of passengers at ordinary fares. 5) Number of passengers at military tariff. 6) Number of passengers carried on special conditions. 7) Number of prisonners and their escorts. 8) Mileage of all passengers at remunerative fares. 9) Average mileage (versts) of a passenger at remunerative fares. 10) Total receipts derived from transport of all passengers at remunerative fare. 11) Total average receipts in respect of each passengers (verst, remunerative). 12) Total number of free passengers. 13) Mileage of free passengers. 14) Average mileage of each free passenger. 15) Total weight of luggage. 16) Pood-versts of luggage. 17) Average mileage of each pood of luggage. 18) Total luggage receipts. 19) Average receipts per pood-verst of

Table X. (Continued.)

luggage. 20) Total weight of parcels and goods by quick freight. 21) Including military effects. 22) Total pood-versts of parcels and goods by quick freight. 23) Including military effects. 24) Average mileage of each pood of parcels and goods by quick freight. 25) Ditto of military effects. 26) Total receipts from parcels and goods by quick freight. 27) Including military effects. 28) Average receipts per pood-verst of parcels and goods by quick freight. 29) Ditto per pood-verst of military effects. 30) Total number of poods conveyed by the piece. 31) Including transports at military tariff. 32) Total number of pood-versts by the piece. 33) Including transports at military tariff. 34) Average mileage of each pood by the piece. 35) Ditto of transports at military tariff. 36) Total receipts from transports per piece. 37) Including transports at military tariff. 38) Average receipts for each pood-verst, of transports per piece. 39) Ditto per pood-verst at military tariff. 40) Total number of poods of cattle. 41) Including cattle at military tariff. 42) Total number of pood-versts of cattle. 43) Including cattle at military tariff. 44) Average mileage of each pood of cattle. 45) Ditto of cattle at military tariff. 46) Total receipts from cattle transport. 47) Including cattle at military tariff. 48) Average receipts for each pood-verst of cattle. 49) Ditto for cattle at military rate. 50) Total receipts from postal traffic. 51) Supplementary receipts from passengers and quick freight transports. 52) Total receipts from all quick-freight transports. 53) Average receipts for each train-verst. 54) Average receipts for 10,000 wagon-axle-versts.

II. — Transports at slow-freight rates and corresponding receipts.

55) Total number of poods of goods conveyed at slow-freight rates per pood and per truck (fully loaded). [Including : 56) passed in transit; 57) conveyed at military tariff]. Analysis of total number of poods of goods by slow-freight; 58) conveyed in the up direction; 59) ditto in the down direction. 60) Total number of pood-versts of goods by slow freight. 61) Including transports at military tariff. Analysis of total number of pood-versts (60) : 62) Transported in the up direction. 63) Ditto in the down direction. 64) Average mileage of each pood of goods by slow freight. 65) Ditto of transports at military tariff. 66) Total receipts from goods by slow freight by the pood and by the wagon (fully loaded). 67) Including transports at military tariff. 68) Average receipts per pood-verst of goods by slow freight. 69) Ditto of transports at military tariff. 70) Total number of poods conveyed by the piece. 71) Including transports at military tariff. 72) Total number of pood-versts of transports by the piece. 73) Including transports at military tariff. 74) Average mileage of each pood of transports by the piece. 75) Ditto of transports at military tariff. 76) Total receipts from transports by the piece. 77) Including transports at military tariff. 78) Average receipts for each pood-versts of transport by the piece. 79) Ditto for transports at military tariff. 80) Total receipts from transport of rolling stock conveyed as goods, but circulating on own axles. 81) Total number of poods of cattle. 82) Including cattle at military tariff. 83) Total number of pood-versts of cattle. 84) Including cattle at military tariff. 85) Average mileage of each pood of cattle. 86) Ditto of cattle at military tariff. 87) Total receipts from cattle transport. 88) Including cattle transported at military tariff. 89) Average receipts per pood-verst of cattle. 90) Ditto of cattle conveyed at military tariff. 91) Number of poods conveyed for the needs of the working at service tariff. 92) Their mileage in pood-versts. 93) Total receipts from service transports. 94) Average tariff per pood-verst. 95) Supplementary receipts from slow-freight transports by slow-freight trains. 96) Total receipts from all slow-freight transports. 97) Ditto per train-verst. 98) Ditto per 10,000 axle-versts of wagons. 99) Number of way-bills at departure. 100) Ditto on arrival. 101) Number of stations of exchange of goods.

III. — Train mileage.

102) Total mileage of trains (versts). 103) Average number of trains per day for the whole line. 104) Mileage of fast and ordinary trains. These include : 105) Special trains for the Imperial family;

106) ditto for private persons; 107) ditto for administration; 108) fast and express; 109) postal and passenger; 110) mixed; 111) military; 112) junction. 113) Average number of slow-freight trains per day for the whole extent of the line. 114) Mileage of slow-freight trains (versts). These include: 115) goods trains; 116) military ditto; 117) administrative ditto; 118) junction ditto. 119) Average number of slow-freight trains per day for the whole extent of the line.

IV. — Mileage of rolling stock.

A. — Locomotive mileage: 120) Total mileage of locomotives. 121) Mileage of locomotives for all trains. 122) Including double-heading. 123) Mileage of locomotives for fast and ordinary trains. 124) Including double-heading. 125) Mileage of locomotives for slow-freight trains. 126) Including double heading. 127) Mileage of light locomotives, *i. e.*; 128) locomotives, alone; 129) reserve; 130) shunting. 131) Proportion per cent of mileage of locomotives without trains to train mileage.

B. — Mileage of cars and axles of cars: 1. *Mileage of home and foreign cars and corresponding axles to home system*: 132) Total mileage of all cars. 133) Total mileage of all axles, *viz.*: 134) *a*) Home stock on home system: cars; 135) ditto: axles. Including: 136) coaching vehicles; 137) ditto: axles. 138) Luggage, postal, service and prisonners' vans: vans. 139) Ditto: axles. 140) Goods wagons. 141) Ditto: axles. 142) *b*) Foreign stock on home system: cars. 143) Ditto: axles. Including: 144) Coaching vehicles: cars. 145) Ditto: axles. 146) Luggage, postal, service and prisonners' vans: vans. 147) Ditto: axles. 148) Goods wagons: wagons. 149) Ditto: axles. — 2. *Mileage of home cars and axles on foreign systems.* 150) Total mileage of cars. 151) Ditto of axles. Including: 152) Coaching vehicles. 153) Ditto: axles. 154) Luggage, postal, service and prisonners' vans: vans. 155) Ditto: axles. 156) Goods wagons. 157) Ditto: axles. — 3. *Mileage of home cars and axles on home and foreign systems*: 158) Total mileage of cars. 159) Ditto of axles. Including: 160) Coaching vehicles. 161) Ditto: axles. 162) Luggage, postal, service and prisonners' vans: vans. 163) Ditto: axles. 164) Goods wagons. 165) Ditto axles. — 4. *Analysis of mileage of home and foreign stock and axles relative to home system for nature of train: a) Mileage of stock in fast and ordinary trains*: 166) Coaching vehicles. 167) Goods wagons. 168) Others. 169) Axles. — *b*) *Mileage of stock in slow-freight trains*: 170) Coaching vehicles. 171) Goods wagons. 172) Others. 173) Axles.

V. — Composition of trains.

Average number of cars and axles. — *a*) *In fast and ordinary trains*: 174) Coaching vehicles. 175) Goods wagons. 176) Axles. — *b*) *In slow trains*: 177) Coaching vehicles. 178) Goods wagons. 179) Axles.

VI. — Number of pood-versts of tare of rolling stock.

180) Total number of pood-versts of tare of rolling stock, *viz.*: 181) Number of pood-versts of tare of locomotives and tenders. 182) Number of pood-versts of tare of cars (home and foreign on home system). Analysis of tare of rolling stock (poods): 183) per train-verst; 184) per 10,000 axle-versts.

VII. — General summary of traffic.

185) Number of passenger-versts per axle-verst of mileage of coaching vehicles. 186) Comparison of number of seats occupied and available per axle of coaching vehicle. 187) Average number of passengers per train. 188) Number of pood-versts per axle-verst of goods wagons. 189) Average number of poods of goods per slow-freight train. 190) Ration of paying load and loading capacity per axle of goods wagon. 191) Number of gross pood-versts conveyed on line.

Table XI. — Data regarding receipts and transports by quick and slow speeds per month (each month separately).

Index number	PASSENGERS AND TRANSPORTS BY QUICK SPEED (57 separate articles of transport).	January.			And so on.	December.			Total.			Total mileage. Versts.	Average mileage.	Average receipts per unit.	Average receipts per verst of mileage.
		Number.	Receipts: roubles.	Receipts: copecks.		Number.	Receipts: roubles.	Receipts: copecks.	Number.	Receipts: roubles.	Receipts: copecks.				

Table XII. — Data regarding quick and slow speed transports by stations (each station separately).

Index number.	PASSENGERS AND TRANSPORTS BY QUICK SPEED (39 articles of transport).	Designation of station on home system: at departure.	Designation of station on home system: on arrival.	Junction stations: at departure.	Junction stations: on arrival.	Total.

Index number.	SLOW-SPEED TRANSPORTS (11 articles of transport).	Designation of stations on home system: at departure.	Designation of stations on home system: on arrival.	Designation of lines: at departure.	Designation of lines: on arrival.	Total.

Table XIII. — **Data regarding station operations (each station separately).**

Index number.	DESIGNATION OF STATIONS AND THEIR CLASS.	Per quarter.	Average number per month.							
			Trains received and despatched :		Coaching vehicles :		Goods wagons :		Poods :	
			quick speed.	slow speed.	at departure.	on arrival	at departure.	on arrival.	loaded.	unloaded.

Note. — Tables I to X form annexes to the budget and annual returns; tables XI to XIV come only within the scope of the annual returns.

ANNEX III.

Table of temporary and periodical statistics regarding the position of the railways and their traffic.

I. — *General data relative to the condition of the railways.*

Annually (on the 1st January).

Working length of line and branches (from centre to centre of stations) *i. e.* : *a*) division into sections of line; *b*) mileage length of the second track; *c*) number and length of connecting lines and branches in private use; *d*) length of all other lines (locomotive, shunting, etc.); *e*) restrictions existing with regard to the circulation of rolling stock of certain types; *f*) arrangement of depots and number of locomotive sheds; *g*) number of trains in each direction corresponding to the distribution of water and to tender capacity; *h*) method of firing on each section; *i*) arrangement of sorting yards; *k*) plans and diagrams of home junction stations and points of exchange of stock, together with maritime and river stations. If there is reason to foresee changes during the course of the year, these will be indicated.

II. — *Transport capacity.*

Twice annually (1st September and 1st March).

These particulars will be given by sections, differing from each other according to degree of transport capacity.

A. — Number of regular trains up and down, leaving daily or periodically, *i. e.* leaving on certain days fixed in advance (express, fast, postal, mixed, total). Their composition (normal in axles) :

1° Coaching vehicles, luggage vans, vehicles for transport of prisoners, etc.;

2° Loaded goods wagons : *a*) up; *b*) down.

B. — 1. Daily number of all other classes of regular or periodical trains (no account being taken of trains included in paragraph *A*), *i. e.* : military trains, emigrant trains, fast goods, etc.

2. Maximum number of loaded axles of goods stock able to be conveyed by these trains in the directions of the traffic : *a*) up; *b*) down.

C. — Maximum number per day of auxiliary trains capable of being dispatched on each section, without counting the trains included in paragraphs *A* and *B* : *a*) using the ordinary installations; *b*) bringing into use all crossing points and auxiliary sidings provided for the commercial service in case of an unusual rush of traffic, indicating in the latter case the number of auxiliary trains.

Independently of these particulars, details are given of :

1. The normal make-up of the trains, *i. e.* the number of loaded axles of goods wagons in the directions : *a*) up; *b*) down.

2. Maximum length of trains corresponding with the length of sidings and others.

D. — Descriptive tables and books of routes.

III. — *Capacity of stations.*

Annually (on the 1st January).

Abstract of the junction stations, terminus stations and important points of departure and arrival of goods, and abstract of all stations where there is reason to fear difficulties in respect of the passage, receipt and departure of goods, with an indication :

1. Of the maximum daily number of wagons which the station can : *a*) load; *b*) unload; *c*) class according to nature of goods; *d*) admit to passage in transit; *e*) make up into trains, and *f*) exchange with neighbouring lines (on condition of receiving an equivalent number of wagons).

These particulars will correspond to the heaviest period of traffic within the limits of the graphic time-tables in force, as well as to the enlargement of stations provided for.

2. Maximum number of wagons capable of being dealt with during a day, with indication of conditions of labour, if the number of wagons does not depend solely on the quantities indicated above.

3. Maximum number of wagons capable of being put into depot at the stations without prejudice to their working capacity : *a*) total; *b*) including reserve wagons.

4. Length of the sidings, classing them by lines : *a*) for dispatch and receipt of trains; *b*) shunting; *c*) loading and unloading; *d*) service.

IV. — *Goods warehouses.*

Annually (on the 1st January).

Abstract of stations, with indication of capacity and platform area for loading :

1. Arrangements for the storage of goods awaiting their turn for dispatch, separately according to nature of goods, sheds platforms, etc.

2. Arrangements for storage of goods arrived and awaiting their delivery to consignees.

3. Long term storage, with indication : *a*) of the nature of the goods, and *b*) of the right of the railway to apply special tariffs according to warehouses : *a*) belonging to the railways, or *b*) incorporated therein.

4. Areas, capable of being placed at the disposition of bulk goods, together with the sheds temporarily appropriated for the use of bulk goods, awaiting their turn for despatch, with an indication of the number of gangs and mechanical appliances available for the loading, unloading and cleaning of the goods, etc. If any changes during the course of the financial year are foreseen they should be carefully indicated.

V. — *Fuel reserve.*

Monthly (on the 5th of the month following).

Particulars given separately for each kind of fuel with regard to the quantity : *a*) total on the 1st of the month; *b*) to hand during the month; *c*) used during the month, and *d*) remaining at the end of the month.

VI. — *Inventory of rolling stock.*

Annually (on the 15th January).

A. — Number of locomotives of each type, with as complete particulars as possible.

1. Series and manufactory.

2. Number and diameter of axles, carrying and driving.

3. Method of firing.

4. Effective force, and type of automatic brake.

5. Date of construction and last renewal of boiler.

6. Heating surface.

7. Boiler pressure and diameter of cylinders.

8. Axle load.

9. Date of last overhaul, and mileage effected since.

10. Tender capacity, number of axles and their loads.

B. — **Coaching vehicles, luggage vans, vehicles for the transport of prisoners, service vehicles, specials, etc.**

Number of vehicles of each type with indication of :

1. Kind (class, speciality, etc.).

2. Tare and number of axles.

3. Description of brakes.

4. Number of compartments (if any), and number of seats; night and day; as regards luggage vans, their capacity.

5. Method of heating and lighting.

C. — **Goods wagons.**

Number of wagons of each type, indicating :

1. Characteristic features of special wagons, and of the goods corresponding.

2. Number of axles.

3. Capacity (as regards open trucks, also the length).

4. Tare.

The brake-vans will be mentioned separately.

E. — **Motor cars.**

Their number, with particulars in each case of the number of axles, passenger seats for each class, and capacity for conveyance of goods.

These data should be for the 1st January. The stock incorporated with the railway will be indicated separately.

VII. — *Modification of inventory.*

Monthly (the 10th of the month following).

Effective force of rolling stock, with classification by categories as indicated in No. VI :

a) Ordered at the manufactories.

b) Received by the railway :

1. Date of receipt.
2. Date of being put into service.

c) Exclusion from its service :

1. Date of exclusion from service.
2. Date of exclusion from inventory.

d) Total modification during the corresponding month *b*-1 and *c*-2.

Care will be taken to indicate under headings *a* and *b* the name of the manufactory, the budgetary credit, and the name of the cessionary railway. Particulars will be given under the heading *c* if the stock has been sold or transferred to the inventory of a foreign railway, and the name of that line stated.

The particulars as a whole of section VII should explain the modifications of the inventory indicated in the abstract for the year (section No. VI).

VIII. — *Distribution of rolling stock.*

A. — **Locomotives.**

Daily (forty-eight hours after the end of the day) average returns per month (per sections of line), two weeks after the end of the month.

These particulars will include the following data :

a) 1° Inventory and 2° number (taking into consideration the hire of stock and its return).

b) 1° Under repair ; 2° awaiting their return for repair, and 3° out of use.

c) Number proper in service : 1° under steam; 2° being washed out, and 3° remaining available (see note 1).

The locomotives under steam will be divided into : working with 1° double crews, and 2° single crews, each category being divided according to the nature of the work : 1° passenger trains; 2° goods trains; 3° service trains; 4° running light; 5° shunting; 6° reserve.

Stoppages : *a*) at stations and in the trains; *b*) awaiting trains.

These records will be kept separately for : 1° passenger locomotives with two driving axles; 2° locomotives with three driving axles; 3° passenger locomotives with four or more driving axles; 4° composite locomotives; 5° goods locomotives with three driving axles; 6° goods locomotives with four driving axles; 7° goods locomotives with six driving axles; 8° tenders and tank locomotives, etc.; 9° motor cars.

The daily reports will furnish data for the whole system; the monthly reports, by sections of the transport (running) service (see note No. 3).

NOTE.

1. The figures inserted under the heading " remaining available " will be completed by an indication of the number of locomotives and wagons available for sending on foreign systems.

2. In order to obtain a more exact account of the mileage of each wagon, the analysis ought not only to show the exchange, the delivery up, the hiring and the debts in wagons, but should further mention the delivery of wagons at a fixed term without actual exchange of stock, as well as the transfer of passenger vehicles from one system to another, when these vehicles effect their mileages in through trains (for example, special saloons, etc.).

3. The analysis of rolling stock is effected at present according to daily reckoning. So far as locomotives are concerned, it will be effected in future according to locomotive hours.

B. — **Passenger vehicles.**

The average figures for each month will be presented two weeks after the end of the month.

a) 1° Inventory; 2° vehicles received and delivered up; 3° balance of the delivery up in through service; 4° remaining total.

b) 1° Under repair; 2° awaiting their turn for repair, and 3° out of use.

c) Inventory of vehicles able to ensure the service :

1. Of commercial and military trains;
2. Serving as lodging and entering into the composition of service trains;
3. Reserve;
4. Remaining available.

A separate calculation will be made for each type of carriage :

1. Special saloons, and service carriages, with two and three axles, ditto with four axles;
2. 1st class with two and with three axles; ditto, with four axles.

A separate account will be kept of carriages of two, three and four axles :

3. 1st-2nd class;
4. 2nd class;
5. 2nd-3rd class;
6. 3rd class;
7. 4th class:
8. Luggage vans;
9. Mail;
10. Prisoners;
11. Others.

C. — **Goods wagons.**

a) 1° Inventory; 2° hired and rented; 3° balance of debts in wagons and wagons delivered up at fixed date; and 4° total inventory.

b) 1° Repairs; 2° awaiting their turn for repair; 3° out of use.

c) Inventory of wagons fit for service :

1. Wagons in use for transport, under loading, unloading, reserve and forming part of the make-up of trains, with the exception of stock designated for passenger, military and service trains, divided into categories, *viz.* :

a) Through-service wagons;

b) Wagons temporarily unfit for through services;

c) Wagons unfit for through services :

2. Appropriated to the requirements of : *a*) service trains; *b*) military, and *c*) passenger.

3. Serving as lodging and for storing;

4. Delayed in course of route : *a*) loaded; *b*) empty.

5. Available surplus (note 1).

Each category will be divided according to the type of wagon, *i. e.* :

1. Covered wagons, normal pattern (with the exception of wagons with four axles).

2. Including wagons appropriated to passenger traffic.

3. Covered, with four axles.

4. Open, flat wagons.

5. High-sided wagons with two axles.

6. Wagons with four axles.

7. Special.

8. Trucks for transport of naphtha.

Covered wagons temporarily appropriated to the special goods service will not be excluded from the total number of covered wagons of normal pattern.

IX. — *Hire of rolling stock.*

Daily, the particulars enumerated under headings a, b, c, d, and, monthly, the data under headings e and f. Time allowed, the same as for section No. VIII.

a) Kind and number of rolling stock hired and rented at the commencement of the period, with indication of the proprietary line and the hiring line.

b) Category and number of rolling stock, returned or received, with indication of the corresponding line.

c) Category and number of stock received or returned, with indication of the corresponding line, and date of return.

d) Category and number of rolling stock remaining as balance of stock hired and rented towards the close of the period.

e) Number of days of renting of stock during the period, divided up according to categories of stock and proprietary or hiring lines.

NOTE.

1. The division according to categories of stock will be identical with that indicated in section No. VIII.

2. To meet the requirements of the technical statistics, each line will deduct the dates of delivery and return upon the basis of its own data, *i. e.*; for each wagon, the date (day) of its transfer by the ceding line or of its return in kind as well as by compensation (by entries); for each locomotive, the ceding line will deduct the day of departure from the depot, if the locomotive has to be transferred anywhere on the line; if the delivery takes place at the station at which the depot is situated, the day of the delivery of the locomotive to the foreign line, and *vice versa*.

X. — *Technical work of rolling stock and sections of line.*

Monthly (four weeks after the end of the month).

A. — Mileages of trains (train-versts).

The mileages will be divided according to categories of trains :

1. Fast; express, postal and passenger.

2. Other passenger trains (mixed, etc.).

3. Military trains.

4. Emigrant trains.

5. Other fast trains.

6. Goods.

7. Service.

8. Extra.

9. Locomotives running light.

All these particulars will be recorded separately according to direction (up and down) and by section of line (note 3).

B. — **Mileages of locomotives (locomotive-versts).**

The whole work of locomotives upon the portions of the line situated between the stations, including double traction (front and rear) will be set out in nine categories indicated under heading *A*, separately for the directions up and down.

As regards the work in the stations, this will be divided into: 1° shuntings by special locomotives; 2° shunting by passenger locomotives; 3° reserve (in the trains, at stations, and awaiting their turn for entry into the composition of trains. as well as at the depots).

The mileages for each of the twelve categories (9 + 3) will be mentioned separately for each section of line and according to the type of locomotive :

1. Passenger with 2 driving axles.
2. — — 3 — —
3. — — 4 — —
4. Mixed-goods — 3 — —
5. Goods — 3 — —
6. — — 4 — —
7. — — 6 — —
8. Tank locomotives.
9. Motor cars.

(Separately for double and single crews.)

C. — **Division of auxiliary mileages of locomotives on portions of the line situated between the stations.**

The mileages will be recorded separately :

1. Driving back.

2. Double traction of trains (by weight).

3. Double traction effected in place of mileages of locomotives running light.

4. Mileages of locomotives running light.

The total of the mileages under headings 3 and 4 will be divided up in accordance with the principal causes, *viz.*: *a*) uneven traffic; *b*) defective organization of running service; *c*) difficulties occurring to traffic; *d*) mileages of service and duplicated trains; *e*) driving back, and *f*) other causes.

These particulars will be furnished according to sections of line and direction of traffic, but divided according to type of locomotive.

D. — **Mileages of passenger vehicles.**

Monthly (four weeks after the end of the month).

The mileages will be declared according to categories of trains indicated in paragraph *A*, separately for the directions up and down, with division of the data per sections of line and categories of wagons as mentioned in section No. VIII-*B*.

E. — **Mileages of goods wagons.**

Monthly (four weeks after the end of the month).

The mileages will be set forth according to categories of trains, by sections and directions of traffic. They will be divided up as follows as regards categories of wagons :

1. Covered wagons, normal pattern, excepting wagons with four axles.

2. Inclusive of wagons appropriated to passenger transport.

3. Covered wagons with four axles.

4. Flat, open wagons.

5. High-sided wagons with two axles.

6. High-sided wagons with four axles.

7. Special.

8. Cisterns for the transport of naphtha.

These particulars will be further divided according to mileages loaded and empty, with subdivision into transports fully loaded; separate packages, animals and passengers.

F. — **Mileages of rolling stock conveyed as goods.**

Monthly (four weeks after the end of the month).

These particulars will be divided according to trains, sections of line, direction of traffic conformably to the indications given in paragraphs *C* and *D*, the mileages in axle-versts being stated separately :

1. Locomotives.

2. Tenders.

3. Passenger coaches.

4. Goods wagons.

G. — **Data concerning the technical working of sections of line.**

Daily (forty-eight hours after the end of the day).

The following particulars will be given separately for each section and by directions of traffic :

1. Number of passenger trains (including extraordinary and service trains).

2. Number of military and emigrant trains.

3. Number of other trains, excepting service trains and others having stops outside of stations.

4. Number of service trains and others having stops outside of stations.

For each category of trains there will be set out the number of locomotives and axles of vehicles with their division :

a) Passengers : saloons, classes, mail, prisoners, etc.;

b) Others : 1° with passengers; 2° loaded; 3° empty.

Trains and vehicles (axles) having passed through the whole section will be indicated separately.

NOTE.

1. Classed as military trains will be trains dispatched by request of the military authorities loaded with soldiers and their effects, even in the case of an additional transport of goods, with a view to a better utilization of the traction.

If these trains circulate in accordance with the time-tables of military trains, but without conveying soldiers or their effects, they cannot be classed as military trains. The same remark applies to emigrant trains.

2. Classed as service (administrative) trains will be those which serve for the conveyance of gangs of workmen charged with the maintenance of the permanent way without previous registration, ballast trains, snow trains, etc.

If, on the other hand, the service transports take place with previous registration, these trains will be classed as goods trains.

3. The mileages of trains circulating upon portions of foreign lines, will be taken out by the proprietary line in accordance with the following rules : *a*) the line to which the train belongs reproduces the indication of the foreign section on table No. 8, recording it separately; *b*) in the case above-mentioned, the rolling stock, during its circulation over the foreign

section, will be deducted from the inventory of the home line.

4. *Ad E*-1. — Covered wagons, temporarily appropriated to special transports, will be taken out as covered wagons of normal pattern.

5. *Ad F*-1. — The particulars given in this column will be taken out for the purposes of the technical statistics, independently of the conditions regulating the transport of foreign stock.

XI. — *Commercial work of rolling stock and sections of line.*

A. — Passenger mileages (passenger-versts).

Monthly (nine weeks after the end of the month).

(According to the issue or registration of passenger tickets).

These data are set out separately according to sections and directions of traffic.

The tickets will be divided up by categories :

1. General tariff for adults :
   - *a*) 1st class;
   - *b*) 2nd class,
   - *c*) 3rd class;
   - *d*) 4th class.

2. General tariff, with division according to class for children's fares.

3. General tariff, with division according to priveleged class (including officers' tickets related to the corresponding classes) and carried at military tariff solely.

4. General tariff with division according to class of free tickets.

5. Soldiers sent by detachments (officers separate).

6. Emigrants.

7. Prisoners and their escort.

8. Goods attendants.

B. — Goods mileages.

Monthly (nine weeks after the end of the month).

These particulars will be set out separately for each section of line and direction of traffic.

The mileages will be divided up as follows :

1. Luggage (including the free pood), parcels and postal packets conveyed apart from the mail vans.

2. Emigrants' effects.

3. Commercial goods at quick-freight rates.

4. Commercial goods at slow-freight rates.

5. Military effects.

6. Service transports, effected by service trains with previous registration.

7. Service transports, effected by service trains without registration.

The data of each category will be analysed according to type of vehicle used for the transport, *viz.* :

a) Luggage vans;

b) Covered wagons, normal pattern, excepting wagons with four axles;

c) Covered wagons with four axles;

d) Open, flat wagons;

e) High-sided wagons, with two axles;

f) High-sided wagons, with four axles;

g) Special wagons, excepting cisterns for the conveyance of naphtha;

h) Cisterns for conveyance of naphtha.

There will be recorded, at the same time, by categories *b*, *c*, *d*, *e*, *f* and *g*, the fully-loaded wagons, the separate packages and transports by the piece.

All transports by the piece will be reduced into poods, and their mileages will be set forth in pood-versts.

The mileages of fully-loaded wagons will be set forth in pood-versts, and in wagon-axle-versts; as regards the mileage of service transports, this will be reckoned only in wagon-axle-versts.

NOTE.

Ad A :

1. There will be indicated the mileage of all passengers whose conveyance will be effected by means of every kind of single or return ticket. The time of the run will relate itself to the date of issue of tickets, etc.

2. Monthly, season or annual tickets issued will be taken out separately according to month, class, section of line, and category of traffic.

3. The mileages of passengers and goods will be taken out according to distance of working covered and distance by tariff.

Ad B :

1. Separate packages presented simultaneously by one and the same consignor and for the same address and in quantity sufficient for the complete loading up of a wagon will be reckoned as a full truck-load.

2. Goods traffic will be reckoned, not according to the date of issue of the way-bill, but according to that of the actual dispatch of the goods.

XII. — *Technical operations of stations.*

A. — Number of trains.

Daily (forty-eight hours after the end of the day).

Particulars of the number of trains and of cars forming part of their make-up, by categories, *viz.* :

1. Having passed in transit (received and dispatched);

2. Made up and despatched;

3. Arrived and broken up.

Each category will be subdivided per species of train :

a) Passenger trains of all kinds : fast, express, postal, mixed, etc.;

b) Military;

c) Emigrant;

d) Others, excepting service trains.

These data will be recorded for junction stations, and stations making up and breaking up trains.

The particulars concerning junction stations will include figures for all directions possible; as regards the remaining stations the details will refer only to the two directions : up and down; in the case of the terminus stations, they will be taken out for one direction only.

If the stations make up long-distance trains, the number of trains of this description will be given, the number of wagons forming part of them, and the receiving stations.

B. — Number of cars.

Daily (forty-eight hours after the end of the day).

1. Loaded or prepared for loading.

2. Unloaded, with analysis of each category, as follows :

a) Coaching vehicles;

b) Goods wagons appropriated to transport of men;

c) Goods wagons.

Loaded goods wagons, arrived for the sorting of separate packages, will be mentioned separately, with indication of the number : *a*) arrived for classification, and *b*) despatched after classification.

A record will be further made of the total number of cars at the station at an agreed hour of each day (cars forming part of the make-up of trains being excepted) separately : *a*) coaching vehicles; *b*) wagons appropriated to transport of men; *c*) loaded goods wagons; *d*) empty goods wagons.

An indication will be made at the same time and for each station, of the number of cars according to categories remaining in the station more than one day, with notification of the causes of delay. The particulars will be given per categories of stations conformably with the indications given above.

C. — **Exchange of stock at junction stations.**

Daily (forty-eight hours after the close of the day).

The following data will be recorded regarding exchanges :

1. Compensation in kind (actual exchange).

2. Others.

Each of the categories will be divided up as follows : *a*) number of cars delivered to foreign lines; *b*) number of cars received; *c*) balance of exchange for the day; *d*) compensated without actual exchange (by entries); *e*) statement of car debts at or about the end of the day.

A separate statement will at the same time be made of the number of loaded wagons : covered, open, and others, together with the empty wagons : covered, open, and others.

3. Quantity of goods, received and transmitted for unloading (without exchange of stock) conformably with paragraph 23 of the Russian railway agreement, the data being analysed according to the gauge of the line.

4. Stock transmitted, conveyed as goods : *a*) locomotives, and *b*) wagons.

5. Number of loaded wagons, awaiting despatch towards the end of the day (at midnight).

These particulars will be furnished for all the junction stations, with the exception of the points of exchange, situated at the terminus stations; all the details will be given according to direction of traffic.

D. — **Exchange between railways of special cars.**

Periodically, conformably with indications from the general management of the railways. chiefly on account of difficulties experienced during periods of extraordinary pressure of traffic.

Record will be made of : *a*) classes of cars; *b*) loaded or empty; *c*) forwarded; *d*) received, and *e*) balance of transfer.

XIII. — *Commercial operations of stations.*

A. — **Issue of passenger tickets, application of stamps to temporary tickets, etc.**

Monthly (nine weeks after the end of the month).

Figures will be given, for each station separately, as to the number of passengers, *viz.* :

a) Ordinary and reduced fares : 1° 1st class; 2° 2nd class; 3° 3rd class.

b) Military tariff : 1° 1st class; 2° 2nd class; 3° 3rd class.

c) Emigrant tariff.

d) Prisoners and their escort.

e) Goods attendants.

f) Free : 1° 1st class; 2° 2nd class; 3° 3rd class.

B. — **Despatch and arrival of goods.**

Monthly (nine weeks after the end of the month).

Data, for each station separately, as to the quantity of goods received and despatched :

1. Fast train, on presentation of passenger tickets.

2. Fast train, without presentation of passenger tickets.

3. Postal packets (outside the postal vans).

4. Emigrant transports.

5. Military transports.

6. Goods by quick freight.

7. Goods by slow freight.

8. Service transports, with previous registration.

To categories 1 to 4 will be consigned the number of poods and number of consignments; as regards categories 5 to 8, there will be separate packages, the full truck-loads and number of corresponding loads and consignments.

The full truck-loads of commercial goods by slow-freight will be analysed according to the number of wagons which have served for the transport of the goods by categories, *viz.* :

1. Cereals in sacks.

2. Cereals in bulk.

3. Coal.

4. Building materials.

5. Building timber.

6. Firewood.

7. Mineral oils in cisterns.

8. Ore, fluor spar, and other minerals, building materials excepted.

9. Iron, cast iron, steel (including rails, girders, and other shaped iron goods).

10. Fresh vegetables.

11. Salt.

12. Hay, straw, grass.

13. Cotton, linen, tow, hemp.

14. Cattle and all kinds of live stock, meats, etc.

15. Sugar.

NOTE.

Ad B. — The despatch of goods will be reported not on the issue of the way-bill, but on the date of the actual despatch on the corresponding section of line.

C. — **Despatch and loading per number of wagons.**

Daily (forty-eight hours after the end of the day).

As far as concerns slow-freight goods, a record will be made of :

a) The despatch ;

b) The loading, the following subdivisions being established :

1. Goods awaiting at the warehouses their turn for loading and others.

2. Goods actually brought into the station and handed over by the warehouses and lifts.

3. Goods of 1st and 3rd category, 4th category, and 5th category.

4. Goods to be transported by obligatory routes or to certain destination stations.

5. Goods to be loaded at the stations, at private sidings, and outside the stations

c) Withdrawal from the sender of the right of despatch of goods :

1. Goods admitted into the stations.

2. Goods handed over by the warehouses and lifts.

d) Balance of goods not loaded; number of wagons and succession fixed, with subdivisions as follows :

1. *a*) In the stations; *b*) in established warehouses; *c*) in the stations with temporary installations; *d*) in the stations without temporary installations, and *e*) in warehouses and lifts.

2. *a*) Goods without fixed succession; *b*) 1st-3rd categories; *c*) 4th category, and *d*) 5th category.

3. By points of destination or sections of transport.

4. By duration of time awaiting despatch : one to five days, five to ten days, and so on.

e) Quantity of goods with address altered or carried over from one order of succession to another.

These data and particulars will be recorded by sections, and in cases where the period of waiting turn exceeds five days, by corresponding destination stations.

As regards other goods, a record will be made of the quantity of goods introduced into the stations and loaded :

a) Quick-freight goods; *b*) emigrant transports; *c*) military transports; *d*) service transports.

Independently of the data referred to above, a note will be kept of the quantity of goods delayed in transit for reasons apart from the transport capacity of the system.

NOTE.

Ad c-b-4 and *d*-3. — The analysis of goods according to directions up and down, and by sections of line, will be made in special registers.

D. — **Arriving and unloading.**

Daily (*forty-eight hours after the end of the day*).

a) Goods arrived at destination.

b) Goods unloaded.

c) Goods handed over to consignees.

d) Goods handed over the warehouses.

e) Goods unloaded awaiting their delivery to consignees or their re-despatch to the warehouses.

f) Goods arrived awaiting unloading.

These data will be recorded by sections of line during the periods of great pressure of traffic, when there is reason to anticipate the overcrowding of the stations, for each station separately.

XIV. — *Speed of traffic.*

A. — **Inclusive speed of goods.**

Monthly (*nine weeks after the end of the month*).

The details concerning each line will be given separately for quick-freight and slow-freight, for full truck-loads and separate packages; with analysis according to categories of goods :

a) Transported on the line in transit.

b) Transported on the line in through service : despatched or arrived on the system.

c) Transported on the line in local service.

Independently of this classification, at the request of the general management of the railways subdivisions will be introduced showing results by categories of goods and by direction of traffic for each line.

B. — **Technical speed of trains.**

Monthly (four weeks after the end of the month).

These particulars will be given monthly by sections of line and by directions of traffic, thus :

1. As regards trains despatched without fixed routes, the duration of the run will be recorded. Dividing it by the mileage, one will obtain the average speed : *a*) of the trains; *b*) of the locomotives (locomotives running light given separately); *c*) of wagons loaded and empty. If the trains circulate upon such sections in part without route and in part with route fixed, the average speed will be given for each category of train separately.

2. In the case of trains circulating with fixed routes, the classes of trains will be recorded separately, thus : *a*) fast, express, passenger and postal; *b*) mixed; *c*) military; *d*) emigrant, and *e*) others, and the duration of delays in arrival at the station of destination, will be given separately for each direction.

XV. — *Circulation of : 1° sheets; 2° screens; 3° fittings for military transport; 4° adaptations for cattle transport.*

Periodically, on the request of the general management of the railways (forty-eight hours after the end of the day).

For each category will be indicated : *a*) inventory; *b*) debts remaining due from the preceding day to foreign railways (with mention of the junction stations); *c*) stock received; *d*) stock transmitted, and *e*) stock remaining (balance) towards the end of the day.

The totals of the different periodical abstracts (monthly, quarterly, half-yearly and annual) will be reproduced in the report and accounts of the financial year for each system. The particulars necessary for the official statistics of the ministry of ways of communication (Annex I to the present memorandum) should be presented separately, independently of the data recorded in the annual returns of each system.

[621 .132.8 & 621 .14]

REPORT

By J. C. INGLIS,

GENERAL MANAGER, GREAT WESTERN RAILWAY, ENGLAND.

In reporting upon porterage, cartage and connecting services by motor car, the elementary position has to be recognised that it has become of importance to railway companies to make some provision for the increasingly smaller units of travel and transport, both in respect of passenger and of marchandise traffic, in order :

a) To hold their own against tramway and other similar competition ;
b) To develop new districts, and
c) To secure additional revenue.

It has long been appreciated in the matter of merchandise traffic that the service afforded by railway companies in the collection at the point of origin and delivery at ultimate destination, or alternatively the bridging over of any hiatus in the throughout route by cartage or other similar services, is an essential factor; but in the matter of passenger and parcels traffic these intermediate services, if they may so be called, have not been looked upon with very much favour, although in big centres of population the parcels delivery van has for many years fulfilled its useful functions on similar lines to the goods delivery van, and with proportionate advantage to railway revenue.

Therefore in developing motor car services for dealing with passenger, luggage, and small parcels traffic such railway companies as have adopted the system, have simply applied the principle to this type of traffic which has already been regarded as indispensable in the case of ordinary merchandise.

The development of the motor car in its twofold application to rail and to road transit has placed at the disposal of railway companies a means of extending their activities into new and hitherto undeloped districts, and of protecting their interests against the new competition brought about by the growth of electric tramway systems and motor omnibus and motor lorry services.

The functions of the rail motor and of the road motor vary somewhat, the former being, of course, confined to the railway lines, while the latter primarily affords means of extension from the railway into surrounding territority.

It will, therefore, be convenient to deal separately with the two systems.

1. — Rail motor cars.

So long as transportation by railway always meant the use of a train consisting of a more or less limited number of vehicles, and, of course, a separate engine, working costs were too high to admit, in normal circumstances, of effective competition with tramways or other road vehicles, and the position confronting the railway companies was that while inroads were continually being made into their territories and traffics by tramways, and latterly by motor buses, they were unable to afford competitive or corresponding services under anything like corresponding conditions. The advent of the rail motor helped the railway companies to some extent in this direction, and its usefulness in connection with suburban traffic, as also for various branch purposes, has now been demonstrated over a series of years in many directions.

The great advantage of the rail motor cars absence of detention and occupation of the road at the termini involved under the old arrangements by the running round of the engine. So serious was this occupation in many instances that it imposed an effectual obstacle in the way of the adoption of supplementary train services on main or through lines, and it is a fact that but for the introduction of the rail motor car, many services on through lines now afforded would not be possible.

One of the features in the situation which had to be met was the necessity of driving from either end of the car, but happily mechanical ingenuity soon proved itself equal to this and no disadvantage is now believed to result from this method of working.

On sections of the line where traffic is too heavy to be dealt with by ordinary rail motors and where the congested state of the lines makes the extended use of ordinary trains impossible, what are known as auto trains have been introduced. These auto trains have a small locomotive in the middle of a number of carriages, say four or five, and the locomotive is operated from either end of the train by the driver.

Rail motor cars are at the present time worked on many of the principal English railways, and have been an importance feature in the development of passenger traffic. Incidentally, as they are of one class only, the cars have tended to the

democratisation of travel, and have helped in the solution of the second class problem, especially on country branch lines, where social considerations made the abolition of the second class more than an ordinarily difficult problem.

Another considerable advantage is the possibility of making stops at suitable intermediate points between stations where sufficient population exists to warrant it, although the traffic is too small to justify the erection of a stations of the ordinary type. The provision of short timber platforms is all that is necessary, tickets being issued by the conductor on the car, and new traffic is thus secured at a minimum of cost.

The single unit motor car also affords a more economical means of maintaining branch line and country services where traffic is usually light, than the employment of an engine and coaches.

Conveyance of parcels, etc., by rail motor car. — The steam rail motor car is undoubtedly the nearest approach to the tram-car that steam railways can provide, and the development of suburban travel by their means is now part of the policy of principal railway companies all over the world. In reviewing the work of the rail motor car, in conjunction with the road motor car services which many of the companies have also established, I have been greatly impressed by the possibilities of developing new business in luggage and light goods, perishable produce, parcels and mail matter by the agency of such services.

The machinery set up for the development of passenger travel might be made greater use of than is generally the case to-day for the baggage and parcels business of the railways.

There is a large parcels carrying business between principal cities and towns and surrounding districts which could be efficiently conducted by means of rail motor services. This is a growing business and apart from the railways is provided for by the state parcels post, by tramways and road parcels carrying companies two use motors parcels vans working far out into suburban and rural districts, and by tradesmen's vehicles.

The conveyance of parcels by rail motors between stations does not differ materially from their conveyance by ordinary trains, but the aim should be to extend this business on existing lines by making use of the Halts and the more frequent service — all the railway companies from whom information has been obtained state that the same conditions apply generally to the conveyance of parcels, luggage and mails by rail motor services as apply in the case of ordinary trains.

Parcels traffic at rail-motor halts. — Arrangements have been made by certain of the English railways — including my own company — to deal with parcels traffic at rail-motor halts; at present only a beginning has been made but experiments in this direction have been successful. The fact that at the majority of halts no per-

manent staff is kept, renders it necessary for the parcels to be brought to the cars and handed to the conductor, the booking of the traffic being performed at adjacent stations where a staff is established.

At some halts a man is employed, and there parcels are received and forwarded in the same way as at small stations.

At other places served by halts, agents have been appointed who meet the cars and receive and forward parcels, receiving a small commission for their services. The agent retains received parcels on his premises until they are called for by the consignees, and if not called for on the day of receipt the consignees are advised of their arrival.

The parcels whilst in the rail motors are under the charge of the conductor and are placed either in the luggage body or in the conductor's vestibule, which can be locked up and made inaccessible from the passenger part of the cars.

It is upon lines somewhat of this character that I am of opinion an appreciable parcels traffic by rail motor car might be built up by those railways running cars, and of course the machinery set up for parcels traffic is equally suitable for dealing with luggage, either accompanied by passengers or otherwise, mails, small goods, and miscellaneous traffic such as milk, eggs, butter, poultry, etc.

Accomodation for parcels on rail-cars. — The construction of rail motor-cars generally is of a fairly uniform type in respect of accommodation for luggage and parcel traffic, nearly all the cars being provided with a luggage compartment, and being capable of hauling one or two passenger and goods trailers if necessary for the accommodation of parcels, milk, farm produce, horses, carriages, etc.

Cost of working rail motors. — The average cost of working rail motor cars in Great Britain may be taken as from 7*d.* to 8*d.* per car mile, which is roughly about half the average cost of working ordinary trains. It will be seen from the particulars furnished as per appendix B, that the cost varies a good deal in different parts of the world, and also with the varying types of car, but apart from this, there is the consideration that different railway companies have different methods of preparing their accounts so that the figures given lose their comparative value to some extent.

2. — Road motor-cars.

In cases where outlying districts of some importance have required to be brought into more direct contact with the railway, the motor-omnibus has proved to be the most useful means of accomplishing the desired end.

In the older civilised countries the most important centres, whether agricultural or manufacturing, are now served direct by railway, and those places which have no railway communication have either not sufficient business to justify a railway exten-

sion, or are suffering from the fact that they do not happen to lie on the direct line of route of a main or subsidiary through line.

In such cases where the population is at all considerable, or the district to be served has any potentiality, schemes for light railway provision have naturally suggested themselves, and amongst the useful purposes which the road motor vehicles serve, is that of demonstrating the value from a transportation point of view of various districts which have been represented as only waiting for the advent of a railway to develop and prosper.

While this has been the case in regard to agricultural neighbourhoods more particularly, certain coast towns and seaside resorts, more or less remote from the railway, and formerly only accessible by primitive horsed conveyance have been brought within the range of an easy and comfortable journey, and have secured prosperity, and the possibility of future development, by the establishment of a road motor service in connection with the nearest railway station, while the advantages which the road motor cars have given to farmers and agriculturalists for the more rapid, direct and reliable transportation of small farm products have been unquestionable.

The superior speed of the motor vehicle has also brought remote places of interest into touch with holiday centres served by the railways and by the fact of enabling passengers to travel there and return home the same day a considerable new pleasure traffic has been built up.

Working costs. — In the case of the Great Western Company, the costs vary in different districts according to the character of the roads traversed, and the description of vehicles used, but the over all cost works out to about 9·94*d.* per mile.

The value of the services is, however, necessarily principally contributive.

Turning to another phase of railway work, the motor-van affords a valuable means of extending the area of collection and delivery of parcels traffic and of accelerating these services, as compared with the general use of horsed vehicles.

Comparing the services rendered by the two classes of conveyance the advantages of the motor-parcels-van may be summarised as follows :

1° Quicker delivery to points at the extremities of the collection and delivery area, and extension of such area;

2° Ability to deal with abnormal traffics without necessitating additional assistance. The motor can be worked double shifts if necessary without undue strain;

3° The employment of fast vehicles for the longer distances relieves the horse stud, and enables a better service to be given by them for the short-distance traffic where the motor costs become higher owing to the small mileage.

Parcels collection and delivery in town areas. — For this purpose a small van of about 12 to 16 horse power with a maximum load capacity of 15 cwts. to 1 ton and a

maximum speed of 20 miles per hour seems to be the most suitable, and if sufficient loading and mileage can be obtained to keep it fully employed a much better service can be given than is possible with horsed vehicles, and at a lower cost.

The working costs of a vehicles of this type, taking all modern improvements and advantage of the experience which has been gained, should work out approximately at £4·12 for a 300 mile week.

Appendices to this report give detailed particulars of the Great Western Company's motor car services and the replies given by other railways to questions put to them on the subject.

APPENDIX A.

Rail motor services on Great Western Railway

Description of cars. — The Great Western cars are of two different types, known as "Suburban" and "Branch" respectively, and are of two lengths 59 ft. 6 in. and 70 feet. The first cost of the 59 ft. 6 in. cars is approximately £1,750 each and of the 70 feet cars £2,000.

The "Suburban" cars are designed to serve districts of an urban character, where large populations confined within comparatively limited areas have to be provided for, and the "Branch" cars are used on country branch lines.

The cars are powerful enough to haul a couple of passenger trailers or several horse boxes or goods vehicles, but in practice it is not considered desirable to attach more than one of the former, or three to four of the latter class of vehicle, although it is sometimes done. The cars will take two trailers on the level.

SUBURBAN CARS.

The underframes are of steel and are carried at one end by the engine bogie, which is suspension hung, while at the vestibule end some of the cars have suspension hung bogies and other bolster bogies.

The cars can be driven from either end and are divided into compartments as follows :.

59 ft. 6 in. cars.

Suburban. — Motor, 14 feet long; smoking, 14 ft. 9 in. long; non-smoking, 26 ft. 7 in. long, and vestibule, 4 ft. 10 in. long. 50 seats, one class.

Branch. — Motor, 14 feet long; luggage or smoking, 6 ft. 3 ½ in. long; passenger, 32 ft. 9 in. long, and vestibule, 4 ft. 9 in. long. 49 seats, one class.

70 feet cars.

Suburban. — Motor, 14 feet long; smoking, 14 ft. 4 in. long; non-smoking, 35 ft. 7 in. long, and vestibule. 4 ft. 9 in. long. 64 seats, one class.

Branch. — Motor, 14 feet long; smoking or luggage, 6 ft. 3 ½ in. long; passenger, 43 ft. 3 in. long, and vestibule, 4 ft. 9 in. long. 63 seats, one class.

The cars are arranged with cross seats of the "walkover" type in the middle, and longitudinal seats, arranged in sets of three, at each end.

Access to the passenger compartment is obtained by means of side doors at the motor end, and sliding doors from the vestibube to the compartment.

Hinged steps are provided on the majority of the cars to enable passengers to enter and alight at the rail level at places where the traffic does not justify the construction of raised platforms.

The lighting is by ordinary or 20 candle power incandescent gas lamps, the gas being stored in cylinders attached to the underframe.

Hand and vacuum brakes, which can be operated from either end of the vehicles, are fitted to each bogie.

Motor. — The cars are driven by a steam motor, using coal as fuel, the capacity of the bunker being 21 cwts.

The cylinders are 12 × 16 inches fixed horizontally on frame of bogie. They drive on to the trailing pairs of wheels which are coupled to the leading pair. The wheels are 3 ft. 6 in. diameter on earlier and 4 feet diameter on later cars. The cylinders have balanced slide valves and the valve motion is of the Walschaert type. The tractive efforts are 7,806 and 6,912 lb. respectively.

Boiler. — Steam is supplied by a vertical boiler with cone top, 4 ft. 6 in. diameter, fitted with 462 tubes $^1/_{18}$ inch diameter.

Height of boiler	9 ft. 6 in.
Working pressure	160 lb.
Heating surface, tubes	605· 9 square feet.
Fire box	46·75 — —
Total	652·65 square feet.
Grate area	11·54 — —

A water tank of 450 gallons capacity is attached to the underframe. The weights on the bogie are :

59 ft. 6 in. cars.

Driving bogie	25 tons 4 cwts.
Trailing bogie	13 — 12 —
Total	38 tons 16 cwts.

70 feet cars.

Driving bogie	26 tons 18 cwts.
Trailing bogie	16 — 5 —
Total	43 tons 3 cwts.

Taking ordinary conditions a motor car without trailer runs about 30 miles, including stops, without taking water,

A later type of car has recently been constructed, the lengths of the compartments being as follows :

70 feet cars.

Motor	14 ft. 0 in.	Luggage	7 ft. 10 in.
Smoking	11 ft. 6 in.	Non-smoking	26 ft. 9 $^1/_2$ in. (61 seats).
Driver's	3 ft. 9 in.	Vestibule	3 ft. 9 in. (1 class).

Fig. 1. — Great Western Railway. — 70 feet rail motor car with centre doors and luggage compartment.

Fig. 2. — Great Western Railway. — Rail motor car with compartment for luggage.

Fig. 2. — Great Western Railway. — Rail motor car with accommodation for passengers desiring to smoke. — 70 feet long.

Fig. 5. — Great Western Railway. — Four-car motor train composed of four 70 feet trailers with covered auto-engine, for heavy suburban work.

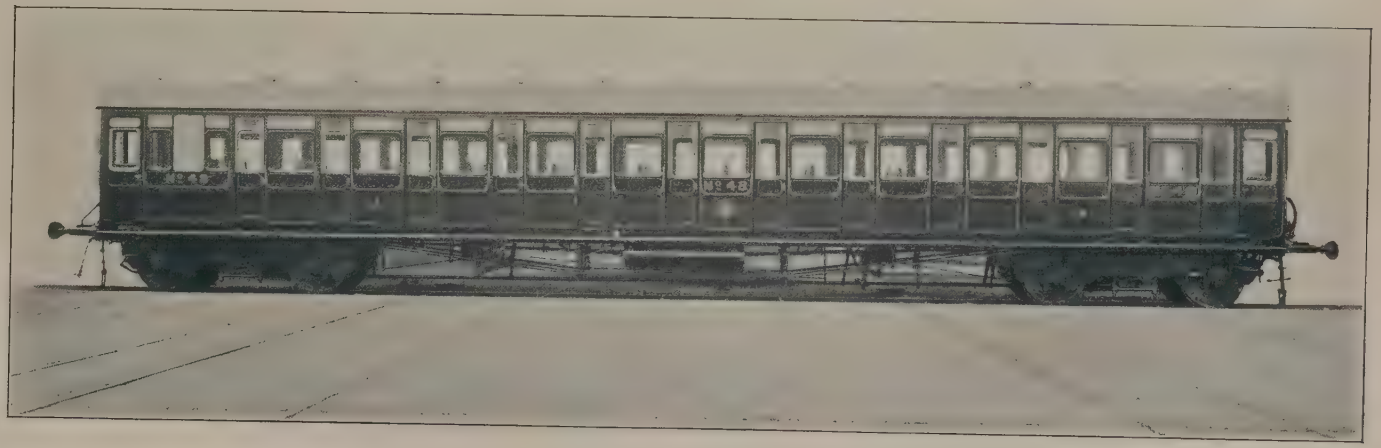

Fig. 6. — Great Western Railway. — Motor trailer with side doors which can be operated from either end of car.

Fig. 7. — Great Western Railway. — 70 feet motor trailer with small engine capable of being driven from either end.

59 f. 6 in. cars.

Motor	14 ft. 0 in.	Luggage	6 ft. 7 1/2 in.
Smoking	8 ft. 6 in.	Non-Smoking	20 ft. 6 in. (45 seats).
Driver's	3 ft. 9 in.	Vestibule	3 ft. 9 in. (1 class).

These cars weigh 43 to 45 tons and 39 tons respectively.

Some illustrations of the various types in use accompany this report.

The company to-day work 35 separate rail motor car services ten of which have been introduced to replace ordinary train services, and the remainder have been put on to provide for the local traffic on new lines, or to augment ordinary train services with a view to cultivating local traffic and to feed trunk line services. Upwards of nine million passengers are conveyed annually by these car services, about 2 1/2 million car miles being run per annum. The cars are booked to run at overall speeds of from 20 to 30 miles per hour.

Cost of working. — The cost of working (exclusive of depreciation and interest) during the year 1908 was 8*d.* per car mile, divisible as under:

Wages	2·72*d.*
Fuel	1·54*d.*
Lubrication	0·18*d.*
Maintenance and miscellaneous expenses	3·56*d.*

Halts. — There are about 140 halts. The cost of constructing them varies fron £150 to £400 according to the character of the halt and buildings, length and height of platforms and nature of site. The majority are provided with shelters of corrugated iron of the standard size 20 × 7 feet with seats. A photograph of one of these halts accompanies this report. At a few important places, the platforms are extended to 350 or 400 feet to accommodate ordinary trains and a booking hall and office of light construction and other necessary accommodation is provided. The cost of these is of course proportionately greater. These halts are developed as the traffic requirements necessitate and so as to accommodate ordinary trains.

Conveyance of mails. — Mail bags are at present conveyed by some of the cars being brought to and taken from them by the Post Office staff. The bags whilst on the motors are under the care of the conductor; generally speaking they are stowed in the conductor's vestibule or in the luggage body, but where the halts are numerous and the absence of the conductor from his car may be frequent, patent hooks are fixed in the vestibule to which the bags are attached and the appliance is locked.

Motor trains. — As a variation from the general arrangement of cars, two rail motor cars and two passenger trailers have been fitted with close couplings, and are designed to run in pairs, each pair consisting of a 70 feet motor car and a 70 feet trailer, an open gangway being provided between the cars, which can be attended to by one conductor. The train seats 143 passengers, 80 in the trailer and 63 in the motor car. This train may be driven from either end and two such sets may be coupled to form a four vehicle train, and when this is done, the engines of the motor cars are placed at the ends of the train for general working convenience.

A multiple train unit has also been designed, consisting of a covered engine of the $\frac{0-6-0}{T}$ type, and two close coupled trailer cars at either end, and the train can be driven from either

end compartments, or from the engine footplate. The train accommodates 312 passengers in all, smoking and luggage accommodation is provided and communication between the smoking and non-smoking porttons is established by means of a doorway. Electrical commutation is provided from the ends of the train for the convenience of the driver and conductors.

When four trailer cars are not required, two cars at either end of the engine may be detached.

Auto-trains. — Auto-trains, which consist of a small locomotive with one or more trailer cars attached are used on branch and local lines in several districts. The engines are of the $\frac{0-4-2}{T}$ and $\frac{0-6-0}{T}$ types, and have been fitted with additional regulator gear, enabling them to be driven either from the engine footplate or from the driver's compartment in the trailer.

Horse boxes, carriage trucks, milk vans, etc., are attached to these auto-trains as circumstances require.

A 70 feet trailer car has also been put into service of a similar pattern to those in use on the Illinois Central Railroad of America which are used for suburban traffic in Chicago. This car has ten side sliding doors which can be close simultaneously by means of a lever in the conductor's compartment at either end, but open independently by hand.

The seats in this car are arranged in the centre crosswise with gangways at either side, giving free access and egress at the side doors.

Figures shewing the various types of car accompanying this report :

Figure 1. . . . 70 feet rail motor car with centre doors and luggage compartment;
- - 2. . . . Rail motor car with compartment for luggage;
— 3. . . . 70 feet rail motor car with accomodation for passenger desiring to smoke ;
— 4. . . . 70 feet motor car and 70 feet trailer coupled, capable of being driven from either end;
— 5. . . . Four-car motor train composed of four 70 feet trailers with covered auto-engine, for heavy suburban work ;
— 6. . . . Motor trailer with side doors which can be operated from either end of car ;
— 7. . . . 70 feet motor trailer with small engine capable of being driven from either end.

APPENDIX B.

Rail motor-cars.

ANSWERS TO ENQUIRIES MADE.

If rail motor-car services in operation, say if self-contained locomotive and carriages, and give description of cars.

Great Central. — Yes, three such services. Engine : four coupled outside cylinders 12 inches diameter in 16 inches stroke, " Walschaerts " valve gear-forms front bogie of coach. Coach frame of ordinary trussed British type with other end carried on 4-wheeled bogie, swing link suspension to each end. Body with longitudinal seats and middle entrance. Luggage compartment at engine end. Driver's compartment at other end.

Lancashire & Yorkshire. — Yes. Engine : outside cylinders, 12 inches in 16 inches stroke, " Walschaerts " valve-gear. Water in tanks in such a position as to give greater adhesive weight on driving wheels. Car body 47 ft. 6 in. long, divided into three compartments. A third class compartment to seat 56 passengers and driver's compartment at rear end. Transverse seats; operated from either end (see fig. 8).

Midland. — Yes. Four-wheel coupled bogie steam motor carriage. Operated either end.

North Eastern. — Yes, two cars. Engine : four cylinder horizontal petrol motor. Cylinders 8 $^1/_2$ inches diameter in 10 inches stroke. Car of ordinary bogie saloon type 52 feet over headstocks. Dividod into three compartments. Forward end contains petrol motor and generator, passenger portion and gangway, rear compartment contains machinery for operating car from either end.

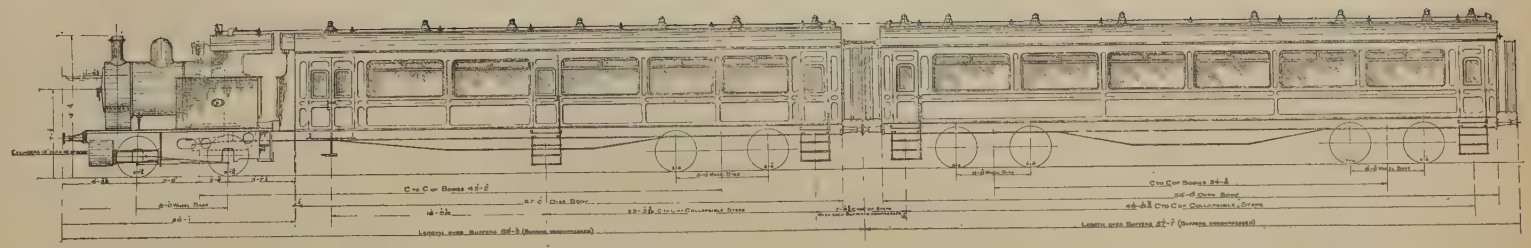
South Australian. — Yes. Steam motor carriage. Engine cylinders, 6 $^1/_2$ inches diameter in 10 inches stroke; 180 lb. working pressure. Some cars can be driven from either end (see fig. 9).

Great Indian Peninsula. — Yes. One car running on short local service. Engine : driving wheels, 3 ft. 5 in. diameter. Cylinders, 9 inches diameter in 15 inches stroke. Steel underframe, teak wood. Regulator handles at either end.

Madras & Southern Mahratta. — Yes. Engine : four wheels coupled. Steel frame. Teak timber body. Operated either end.

North Western India. — Yes. Engine : outside cylinders, 9 inches diameter in 14 inches stroke; single driver; wheels, 3 ft. 3 in. diameter, valve motion. Weight on driving wheels, 14·5 tons. Car; luggage compartment; third class, 70 passengers; second class, 5 passengers; first class, 5 passengers. Operated either end.

Central South African. — Yes. Engine : four wheels coupled, frame of ordinary plate construction. Car, one end carried on ordinary carriage bogie of strong construction while other



Weight empty.	14 t. 6 c. 0 q.	13 t. 4 c. 2 q.	14 t. 10 c. 3 q.	13 t. 2 c. 0 q.
Weight in working order.	16 t. 2 c. 0 q.	16 t. 12 c. 0 q.	14 t. 16 c. 0 q.	
	To seat 56 passengers.			To seat 72 passengers.

Weight of coach empty	42 t. 1 c. 1 q.	Heating surface : tubes	455 square feet.	Boiler pressure	180 lb. per square inch.
— in working order	47 t. 10 c. 0 q.	— — : firebox	54 — —	Grate area	9·4 square feet.
— of coach and trailer empty	68 t. 5 c. 1 q.			Tank capacity	550 gallons.
— in working order (exclusive of passengers)	73 t. 14 c. 0 q.	Heating surface : total	509 square feet.	Quantity of coal	1 ton.

Fig. 8. — Lancashire & Yorkshire steam motor rail coach and trailer.

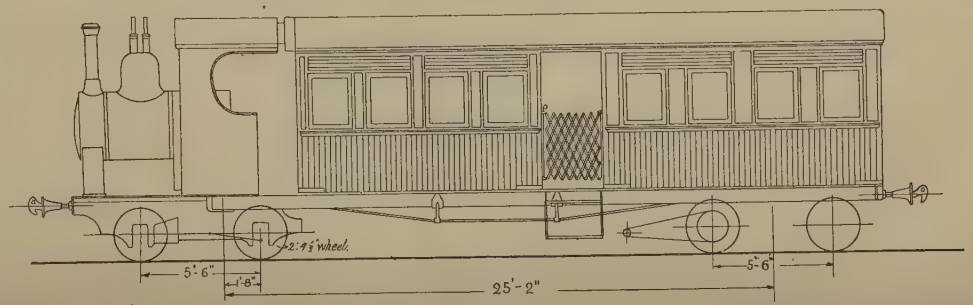


Fig. 9. — South Australian Railways. — Steam motor carriage No. 1. 3 ft. 6 in. gauge. — 180 lb. working pressure; cylinders, 6 1/2 inch diameter × 10 inch stroke.

end rests on the engine frame, the latter therefore carries the weight of its own engine and boiler and also part of the weight of the car. Operated either end. Four compartments, *viz.* : luggage compartment next to engine; compartment to accommodate, 24 passengers; compartment to accommodate, 24 passengers; driver's compartment.

New York, New Jersey & Western Railroad (Erie Railroad Company). — Yes, gasoline, 200 horse-power, steel frame, steel body, cannot be operated either end.

Buenos Ayres Great Southern. — Yes. Engine : outside cylinders, 9 inches diameter in 15 inches stroke; " Walschaerts " valve gear, operated either end of car. Car : Pullman type, first class, second class and luggage compartments.

Austrian State Railways. — Yes. Steam motor cars. Komarck system, upright boiler : steam motor cars, Serpollet system, normal Serpollet boiler and twin engine. Benzolin motor car. Daimler with vertical four cylinder benzin motor with mechanical power, transmission by cog wheels.

In every case the wagon body and engine are connected in one piece with the frame. Can be operated either end.

Hungarian State Railways. — Yes. Steam motor cars, 35 horse-power and 50 horse-power engine. Ganz & C°. Total length, 38 feet. 9 second and 24 third class passengers, or 38 third-class passengers. Cannot be operated either end, but cars under delivery will be capable of being so operated.

Paris, Lyons & Mediterranean. — Two types of motor cars :

First type : The generator and motor are carried on the chassis of the same carriage, seating capacity of cars varying from 36 to 55 passengers. Cannot be operated either end.

Second type : The generator and motor are carried by a special truck. The body of the coach is separate from this truck, but it is so arranged that it can be coupled to any motor truck. Seating capacity of cars 12 first class, 29 third class. 12 passengers on platform at end. Luggage compartment.

French State Railways. — Yes. Up to present trials only have been made. Engine of compound type, four cylinders arranged in pairs which act on front axle by means of articulated chain. Body. Front platform for driver and boiler. Luggage body. Second and third classes, and a rear platform with standing room. Can only run in one direction, have to be turned.

Italian State Railways. — Yes. Combined locomotive and van. Engine vertical boiler, two cylinder motors 11 diameter in 15 3/4 inches stroke. Body consists of three compartments : 1° engine and boiler; 2° postal packages; 2° luggage. Length, 27 ft. 10 in.; width, 9 ft. 8 in. Must run with engine in front.

Swiss Federal Railways. — Yes. Ordinary trains in one district supplemented by a motor car. Double axle wagon of which one axle is driven by a four cylinder benzine motor of the Daimler type. Can be driven in either direction.

Cost of working per car mile

Great Central. — 4·682*d.*

Midland. — 7·67*d.*

North Eastern. — 5·299*d.*

South Australian. — 10*d.*

Great Indian Peninsula. — 6·5*d.*

North Western India. — 9*d.*

Central South African. — 11·8*d.*

New York, New Jersey & Western. — 1*s.* 3*d.*

Buenos Ayres Great Southern. — 2*s.* 3·5*d.*

Austrian State Railways. — Komarck, steam : 3·07*d.*; Serpollet, steam : 2·95*d.*; Daimler, benzolin : 3·02*d.*

Hungarian State Railways. — de Dion Bouton, steam : 5·18*d.*; Stoltz, steam : 8·26*d.*; benzine, electric : 4·04*d.*

Arad Railways, Hungary. — Daimler, petrol : 2·98*d.*; Ganz steam : 2·87*d.*; de Dion petrol electric, 20 horse-power : 2·76*d.*; 70 horse-power : 3·58*d.*

Are trailers attached for heavy traffic?

Great Central. — Yes, but not regularly, two bogie coaches is maximum number that can be hauled up 1 in 100 at 20 mile per hour.

Lancashire & Yorkshire. — Yes for passengers.

Midland. — Yes, one car only is allowed to be hauled.

North Eastern. — No.

South Australian. — Yes, one vehicle only being used.

Great Indian Peninsula. — No, car run up to 30 mile per hour.

Madras & Southern Mahratta. — Yes, two cars maximum which can be hauled.

North Western India. — Yes, two bogie third class coach only.

Central South African. — No.

New York, New Jersey, & Western. — No.

Buenos Ayres Great Southern. — No, when traffic is heavy train engine and ordinary carriages are substituted. Maximum weight that can be hauled is 120 tons or three Pullman Cars.

Austrian State Railways. — Komarck Motors can draw two or at most three trailers.

Hungarian State Railways. — Motor Cars travel alone or with one to three trailers.

Paris, Lyons & Mediterranean. — Yes, one or two trailers.

French State Railways. — Yes, one trailer usually attached.

Italian State Railways. — Yes. Passenger service made by trailers. Five ordinary or axle trailers can be taken. Motor must always be in front.

Swiss Federal Railways. — No.

Accommodation provided by cars.

Great Central. — First and third class smoking and non-smoking compartments.

Lancashire & Yorkshire. — All third class to seat 56 passengers. Accommodation for luggage in a limited degree, and for non-smokers.

Midland. — First and third class. Smoking and non-smoking compartments. Accomodation for luggage.

North Eastern. — Only one class and ono compartment. Accommodation for luggage.

South Australian. — First and second class non-smoking. Accommodation for luggage.

Great Indian Peninsula. — First and third class. Accomodation for luggage.

Madras & Southern Mahratta. — Accommodation is for more than one class. Accommodation for luggage.

North Western India. — First (5 passengers), second (5 passengers), third (70 passengers). Accommodation for luggage.

Central South African. — 28 firsts, 24 second class passengers. One car provides for 48 passengers one class only. Accommodation for luggage.

Buenos Ayres Great Southern. — 28 firsts, 24 second class passengers. Smoking allowed both compartments. Accommodation for luggage.

Austrian State Railways. — Every motor car train carries two classes. Motor car itself only adapted for one. All cars provided with luggage carriers.

Hungarian State Railways. — Second class, and third class 24 passengers, or 38 third class passengers. Smoking permitter on trailers only. Accommodation for luggage and mails.

Paris, Lyons & Mediterranean. — Two classes, no special compartments for smoking. Accommodation for baggage.

French State Railways. — Two classes of passengers, second and third. Seating, 24, standing, 12. No special compartments for smoking. Accommodation for luggage.

Italian State Railways. — No passengers, only luggage and postal packages. Passenger service made by trailers.

Swiss Federal Railways. — Third class only. Smoking allowed on car platform. Accommodation for luggage.

Is luggage and parcels traffic deals with at halts?

Great Central. — Yes.

Lancashire & Yorkshire. — No.

Midland. — Only passengers' personal luggage.

North Eastern. — No.

South Australian. — Yes, by traffic porter who sees that the proper freight charge is made. A covered van used for goods traffic at stations.

Madras & Southern Mahratta. — Yes.

Central South African. — Yes.

New York, New Jersey & Western. — No.

Buenos Ayres Great Southern. — No halts.

Austrian State Railways. — Over a section of line luggage and goods are not conveyed by motor car. On some sections luggage is dealt with, but goods only at places where facilities are provided. On a section where goods are not conveyed by motor car an ordinary goods truck is attached for this purpose.

Hungarian State Railways. — No.

Paris, Lyons & Mediterranean. — Yes. By conductors and porters.

Italian State Railways. — Only where there is the necessary accommodation.

Swiss Federal Railways. — No.

Wurttenberg State Railways. — Yes, when necessary accommodation is provided. When this is not provided luggage is taken on train and booked at first available station.

GENERAL REMARKS.

Development of rail motor on Arad railway. — The Arad and Csanader joint railways of Hungary seem to have made considerable strides with petrol-driven rail motor-cars. In 1903, the management found it necessary to provide additional rolling stock, and for the reason, amongst others, that the construction of the line was of a somewhat light nature, it was determined to work the system by running frequent small units instead of the small number of complete train which had been used formerly.

After experiments with one petrol and four steam cars, the company decided to adopt a system of combined petrol and electric drive, and a number of cars worked on this principle were ordered. Two types were introduced — one of 20 to 30 horse-power for slow traffic and one of 70 horse-power for the fast trains.

The 20 to 30 horse-power cars run at a speed of about 20 miles per hour-full speed being attained in approximately two minutes from starting — and carry sufficient petrol for a run of 360 kilometres. The 70 horse-power cars attain a speed of from 35 to 40 miles per hour in from 1 to 1 $^1/_2$ minute from starting.

Union Pacific Railroad. — The Union Pacific Railroad of America, starting in 1905 with one rail motor car, have now in service a number of motor-cars driven by the internal combustion engines, which have been constructed by the company in their shops at Omaha. Considerable success has attended these services from the commencement. They are fitted with vertical six-cylinder water cooled engines, arranged transversely in the frame, the drive coming practically direct through a metal to metal clutch, change-speed gear, and thence by means of a single heavy chain to the driving axle. Both accumulator and magneto ignitions are fitted, and the

engine is started up by means of compressed air. As regards costs of operation, these seem to vary greatly in the United States, but so far as the Union Pacific is concerned it is understood that they average from 6*d*. to 7 ½ *d*. a mile, the unsettled cost of fuel and density of traffic affecting the matter greatly.

Paknam Railway Company. — The Paknam Railway Company of Siam have adopted a type of Petrol Rail Motor Car for the conveyance of passenger and goods traffic. On the trials, the vehicle carried a load equal to 40 passengers and negotiated an upward gradient of 1 in 40, with a 9 chain curve at 15 miles per hour. The fuel may be either petroleum (kerosene) or petrol spirit. Sufficient fuel is carried for a total run of about 300 miles.

Chicago Rock Island & Pacific Railroad. — The Chicago Rock Island & Pacific of America have adopted a steam motor car of steel constrction throughout the vehicle being of the self-contained type containing engine room, baggage room and passenger compartment, having seating accomodation for 40 persons, with lavatory attached. During trials this car shewed high speed capabilities, on several runs speeds of 60 miles per hour being obtained.

APPENDIX C.

Road motor services on Great Western Railway.

Type of cars. — The Great Western Company of England operate 29 road motor car services or the conveyance of passengers, parcels and goods traffic, and employ altogether 112 cars of various types, all driven by petrol engines (except one steam wagon, and two steam tractors used for heavy goods work, and two electric lorries).

The bodies of the cars are being standardized into four types, *viz.* :

See figure 10. . . . 1° Double deck omnibuses accomodating 36 passengers.
— — 11. . . . 2° Single deck omnibuses accomodating 20 passengers and 15 cwts. of parcels and luggage.
— — 12. . . . 3° Observation or char-a-banc cars. accommodating 30 passengers.
— — 13. . . . 4° Composite car accomodating 20 passengers and 1 ton of parcels or goods. When not requiredfor this purpose, the goods compartment is available for smokers.
— — 14. . . . 5° Double deck omnibuses, with luggage compartment, accomodating 32 passengers and 10 cwts. of parcels or luggage.

The weight of the cars unladen varies from 3 1/4 to 4 1/2 tons according to the type of body, and they are all fitted with solid rubber tyres purchased from approved makers.

Working arrangements. — The cars run in connection with the train service, and are times dat an inclusive speed of 8 to 10 miles per hour. The mileage per car per day ranges from 40 to 80 miles. A spare car (or cars) is kept to ensures reliability of service and to provide for heavy traffics.

Fares, etc. — Passenger fares are arranged on the basis of 1 1/2 *d.* per mile, but this has occasionally to be varied to meet special local circumstances. Season tickets are not issued, but with the view of encouraging frequency of travel, books of tickets are sold at reduced rates. In special cases, cheap return tickets are issued in connection with railway journeys to golfers and fishermen, and for market purposes. The bell-punch system is employed, except in the case of through rail and road bookings, when card tickets of the usual railway pattern are used.

Through ordinary tourist or excursion bookings by rail and road motor car are in operation to a number of seaside places and country holiday resorts.

Full fares are charged for all seats occupied, whether by children or adults.

Reliability. — As the staff have gained experience in their work the reliability of the cars has improved. The following figures show the results achieved at some of the principal centres during the half-year ended December 1908 :

CENTRE.	Number of failures.	Car mileage.	Miles per failure.
A.	Nil.	31,667	...
B.	Nil.	14,555	...
C.	1	20,162	20,162

Fig. 10. — Great Western Railway. — 20 horse-power 2 ton Milnes-Daimler chassis, fitted with standard double-deck body. Accommodation 16 passengers inside, 18 on top deck, and 2 on front seat. Maximum speed : 12 miles per hour.

Fig. 11. — Great Western Railway. — 20 horse-power 2 ton Milnes-Daimler chassis, fitted with single-deck body. Accommodation 20 passengers, and 15 cwt. luggage. Speed : 12 miles per hour.

Fig. 12. — Great Western Railway. — 28 horse-power Durkopp chassis, fitted with observation body. Accommodation 27 passengers. Maximum speed : 12 miles per hour.

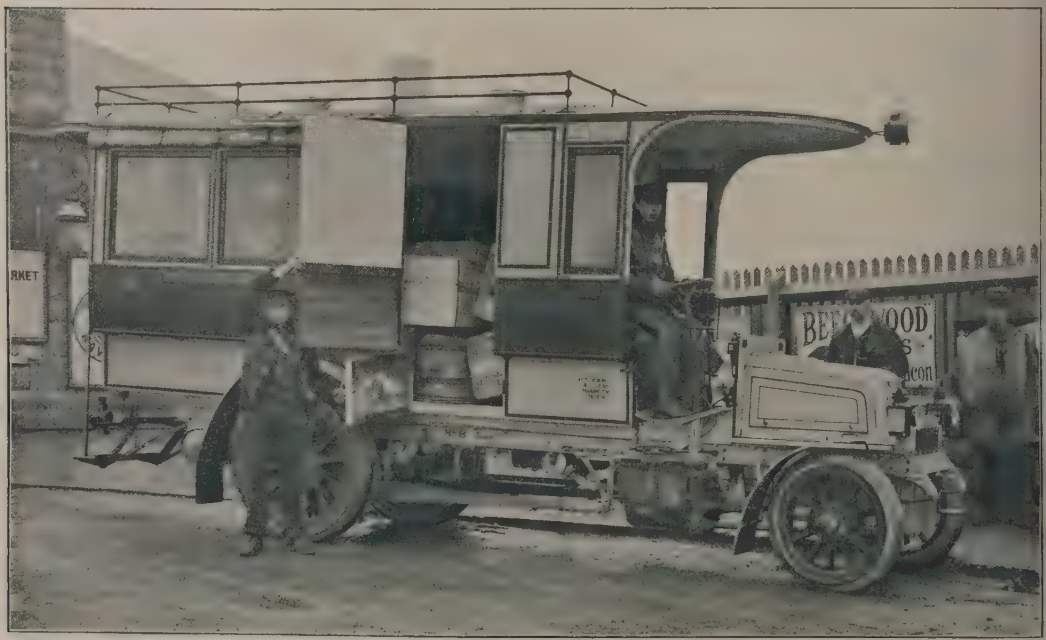

Fig. 13. — Great Western Railway. — 20 horse-power 2 ton Milnes-Daimler chassis, fitted with composite goods and passenger body. Accommodation 12 passengers, and about one ton in goods compartment and 15 cwts. on roof. Maximum speed : 12 miles per hour.

Fig. 14. — Great Western Railway. — 30 horse-power Milnes-Daimler chassis, fitted with special double-deck body, with luggage compartment. Accommodation 32 passengers, and about 10-15 cwt. goods. Maximum speed : 12 miles per hour.

Fig. 15. — Great Western Railway. — Standard road motor car shed, with office for driver (on right) and stores behind office.

Fig. 16. — Great Western Railway. — Electric goods lorry, driven by storage batteries. Capacity, 2 ton.

Fig. 17. — Great Western Railway. — Typical rail motor halt.

Receipts and expences. — The receipts per car mile for the half-year ended December 1908 amounted to 1*s.* 0·34*d.* and the working expenses per car mile were 9·94*d.* including maintenance but excluding renewal.

	Per car mile.
Wages	3*d.*
Lighting and lubrication	0·38*d.*
Traffic materials, etc.	0·10*d.*
Motive power	1·16*d.*
Maintenance, cars	2·38*d.*
— tyres	1·80*d.*
Miscellaneous	1·12*d.*
Total.	9·94*d.*

A number of cars have been running for over five years, and are still working as economically and efficiently as at first. Even if they should be superseded for passenger work by more up-to-date vehicles they can still be used for many years in the capacity of goods lorries.

Development of traffic. — With regard to the contributive value of road motor services to the railway, some special records have been taken from time to time of the amount of traffic brought to and taken from the railway stations by the cars, and the results on some typical services are shown over :

SERVICE.	Total number of passengers carried.	Percentage of rail passengers.
A.	952	55·98
B.	446	73·99
C.	473	62·79
D.	392	73·46

SERVICE.	Parcels.	Percentage rails-borne parcels.
A.	25	92
B.	179	72·62
C.	188	100
D.	102	100

The extent to which traffic can be developed by improved facilities is indicated by the following instance :

Passengers conveyed by subsidized coach from April 1905 to April 1906 (Coach service on 14 April 1906)	6,191
Passengers conveyed by car from April 1906 to April 1907	18,220
Increase.	12,029
	= 194 per cent.

Parcels, etc., by road car. — Parcels, luggage and light goods traffic is conveyed by all the

road motor services operated by the Great Western Company, with the exception of three urban services where the route of the car is covered by the ordinary parcels and goods collection and delivery arrangements.

Parcels, etc., rates and arrangements. — Passengers' luggage. — Small hand luggage under the passenger's own care is carried free. Other luggage not exceeding 1 centweight each package, which can be conveyed without inconvenience, is charged for a the following rates :

2*d.* per package up to	56 lb.	Up to a distance of 6 miles.
4*d.* — —	112 —	
4*d.* — —	56 —	Up to a distance of 12 —
6*d.* — —	112 —	
6*d.* — —	56 —	For distance over 12 —
8*d.* — —	112 —	

Luggage in advance. — Passengers' luggage in advance subject to the usual conditions, is conveyed at charges of 6*d.* and 9*d.* per package, according to distance in addition to the charges for conveyance by rail.

Parcels. — Parcels and small packages not exceeding 1 centweight each package are conveyed at the following charges :

Not exceeding 7 lb. in weight	2*d.*	For distances up to 12 miles.
— 28 — —	3*d.*	
— 56 — —	4*d.*	
— 112 — —	6*d.*	
— 7 — —	3*d.*	For distances over 12 miles.
— 28 — —	4*d.*	
— 56 — —	6*d.*	
— 112 — —	8*d*	

Bicycles and perambulators which can be carried without inconvenience, are conveyed at a charge of 1*s.* each, and folding mail carts at a charge of 6*d.* each.

Newspapers. — Single newspapers are conveyed by the cars at a charge of $^1/_2 d.$ each.

Rates for goods traffic. — Consignments of goods traffic not exceeding 5 cwts. are charged for at the rate of 9*d.* per cwt. (minimum charge 4*d.* per package) and for consignments exceeding 5 cwts. the charge is 6*d.* per cwt. (minimum charge 3*s.*), provided the latter can be split up, if necessary, and carried on the cars at the company's convenience.

All charges have to be prepaid.

In addition to these arrangements, parcels traffic is booked through between places served by the cars and all Great Western Railway Stations, the local motor charges given above generally being added to the rail charges. Rail-borne traffic carried by the cars to two or three important places beyond the rail head, is, however, charged through to destination at the railway rates.

Luggage, parcels, etc., are usually carried on the roofs of single-decked cars, which are designed to take weights of 15 cwts. (see figs. 11 and 13). A special composite passenger and goods car (see fig. 13) is in use on some roads where this traffic is above the average. Cars of this type are also used for heavy mails. In the case of services worked by double-deck cars, accommodation is provided either by removing one or two of the top seats, or by the provision of a luggage compartment, as shown in figure 14.

The parcels agents, who are usually small shop-keepers, are remunerated by the payment of commission on the following scale :

Parcels up to 28 lb.	$\frac{1}{2}d.$ per parcel.
— over 28 lb.	$1d.$ —

The conductor of the car is responsible for the traffic while in transit, and for handling it over to the station master or agent, as the case may be, at destination. Parcels may be accepted by the conductor *en route*, and in such cases he collects the charge and fills up, in duplicate, a way-bill, one copy of which is kept by him and handed in at the station with the cash collected, while the other is given to the sender as a receipt.

The charges on rail-borne traffic are dealt with by the station in connection with which the road cars work.

The charges on passengers' luggage, bicycles, etc., are collected on the cars, and a ticket drawn in duplicate, one copy being handed to the passenger, and the other retained by the conductor, and checked with cash paid in by him.

Mails. — Postal matter is conveyed by the cars on eight different routes, by arrangement with postal authorities, who pay an agreed sum per annum in each case. The mails are in the charge of the motor conductor.

Development of parcels traffic — The following statements show the percentage of parcels-traffic to passenger-traffic on some of the road-motor services, and the progressive growth of the parcels business :

SERVICE.	Proportion of parcel traffic to passenger traffic.	SERVICE.	Proportion of parcel traffic to passenger traffic.
A.	22·5 per cent.	C.	19·4 per cent.
B.	31·5 —	D.	15·1 —

Total parcels and goods traffic in year :

SERVICE.	1905	1906	1907	1908
	£	£	£	£
A.	86	111	136	160
B	Service not established.		141	192
C.	...	...	124	197
D.	...	50	89	92
E.	...	179	203	223
F.	67	92	91	118

No separate accounts are kept as to the cost of dealing with parcels traffic as distinct from the other classes of traffic, but as the same establishment of cars and staff would be employed, and the same mileage run for passenger purposes alone, the only expense incurred is in the payment of commission to agents and the small amount of clerical and porterage work necessary at the station from and to which the cars run.

APPENDIX D.

Road motor-cars.

ANSWERS TO ENQUIRIES MADE.

Are road motors in use, and what type?

Great Eastern. — Twenty-one petrol motors in use in country districts for conveyance of passengers, parcels and light goods. Carrying capacity 30 to 36 passengers, and in certain cases about 1 ton of luggage and parcels. Twelve of these built in company's own works.

Lancashire & Yorkshire. — Only two petrol motor omnibuses employed. Not sufficient experience yet obtained to give information of any value.

Midland. — Two petrol motor omnibuses in use conveying parcels, as well as passengers.

North Eastern. — Sixty-seven petrol omnibuses with accommodation for passengers and parcels in use.

Southern of France. — A summer service of three cars carrying passengers, luggage and parcels is run by a contractor under agreement with the company. This has replaced a former horsed vehicle service.

Bavarian State Railways. — Fifty-eight petrol driven passenger cars and 32 passenger car trailers in use in country districts. Motor vans also used for conveying mails between station and post office in Munich. All petrol vehicles.

What arrangements are in force for dealing with parcels, luggage, etc, traffic by motor in country districts?

Great Eastern. — Charges for parcels : 14 lbs., 4*d.*; 28 lbs., 6*d.*; 112 lbs., 9*d.*
Maximum weight 1 cwt., except in certain cases where it is restricted to 14 lb. Inflammable traffic not conveyed.
No through booking arrangements exist and special scale of rates in force.
In some cars a special compartment for goods provided. Small and luggage carried free.
Other luggage charged 4*d.* up to 56 lb.; 6*d.* up to 112 lb. Maximum weight 1 cwt.

Midland. — Cars convey parcels as required. No other particulars furnished.

North Eastern. — Charges from 2*d.* to 4*d.* according to distance. Maximum weight 1 cwt. Fish, inflammable articles and bulky packages not carried. Hand luggage carried free. Other luggage 3*d.* per package. Maximum weight 1 cwt.
Through bookings in force to limited extent.

Southern of France. — Contractor establishes Receiving Offices at points required by company. Parcels delivered but not collected. Not extra charge for delivery. Charges according to mileage scale. Parcels booked through luggage up to 30 kilograms (66 lbs.) per passenger carried free. Excess luggage charged on mileage scale.

Mails carried in special van provided for purpose.

Bavarian State Railway. — Depots provided at which parcels, etc., are collected and delivered. Traffic is taken to and from depots by senders and consignees themselves.

Charges : 80 per cent of the customary freight of the place. No maximum weight.

What arrangements are in force for conveyance of postal packages by road motor.

Great Eastern. — Special arrangement in force for conveyance of one bag daily by one of the services.

North Eastern. — About three bags per day conveyed. Payment 4*s.* per week.

Bavarian State Railway. — Services are combined mail, passenger, and luggage. Value articles carried in lockers under seats. Conductor, who is in postal service, responsable for mails.

Wurtemberg State Railway. — Postal administration run motor mail vans.

What arrangements in force for dealing with parcels traffic by motor vehicle in urban areas?

Midland. — Four petrol driven parcel vans in use. Two cylinder, horse-power 12 to 16. Capacity 1 to 2 tons.

North Eastern. — Three motor vans (Durkopp) in use in Newcastle.

Bavarian State Railway. — Four Daimler motor vans in use in Munich. Horse-power 11 to 16. Speed 20-28 kilometres (12·4-17·4 miles) per hour. Capacity, $^3/_4$ to 1 ton.

Have replaced 16 drivers and 17 horses.

Heavy goods work in town areas.

Great Central. — Five 5-ton steam and petrol motor lorries, all approximately 35 horse-power with speed of 5 miles per hour in use. Have replaced three 2-horse teams in London, and two 2-horse and one 1-horse teams in provinces.

North Eastern. — Six steam wagons in use. Capacity 5 tons, speed 5 miles per hour.

Steam wagons compare unfavourably with horses when full loads not obtained. Petrol vehicles on short trial found cheaper than horses.

Orleans Railway. — Two steam wagons in use in Paris. Speed 8 to 12 kilometres (5 to 7·5 miles) per hour, load 6 tons. Cost per ton : steam wagons, $^2/_6$ *d.* horse wagons, $^2/_{10}$ *d.*

Italian State Railways. — Twenty-five St. Pancras steam wagons in use. Speed, 7 $^1/_2$ miles per hour; capacity, 5 tons; trailer, 3 tons.

Working costs.

SECTIONAL DISCUSSION

Meeting held on 9 July 1910 (morning).

MR. COLSON, IN THE CHAIR.

The President. (In French.) — Mr. Coventry has kindly undertaken to give a summary of Mr. Inglis's report to the meeting.

Mr. Coventry, Great Western Railway. — I have been entrusted, in the absence of Mr. Inglis, with the task of summarising his report upon motor car services. In his report, Mr. Inglis points out the importance of the railway companies making provision for the transport of increasingly smaller units of travel and transport over short distances, in order :

1° To hold their own against tramways and other similar competition;

2° To develop new districts;

3° To secure additional revenue.

In regard to merchandise traffic, the service of collection from point of origin and delivery at destination has long been undertaken by railway companies within a comparatively short radius of their stations. For passenger traffic even these intermediate services have in the past not been thought to be of much importance, and no attempt has been made to collect either passenger or merchandise traffic from towns or villages situated at a distance from the line, but still within the sphere of influence of the railway. This traffic will have to be encouraged in the future and rail and road motors seem to be the best means of dealing with it.

These two types of motor cars, of course, serve different purposes; the rail motor car can only be used on the railway lines, whilst the other is run on the ordinary roads and streets.

These distinctions being understood, the report first deals with rail motor cars, which have also been mentioned in another section of the Congress.

The Great Western Railway brought these motors into use, having found that the cost of trains was too high to enable them to compete with the tramways. Thanks to the rail motor car, the Great Western Railway has been able to meet this competition with success.

The motor cars have three great advantages over the complete trains with separate engines :

1° They do away with, or entail less use of, transfer roads at terminal stations. Indeed, a larger number of new trains from both main line and branch line, can now use the big stations, the running lines of which are no longer encumbered by local trains;

2° Only one class being provided, the cars have helped in the solution of the second class problem, a very real difficulty on country branch lines owing to social considerations;

3° Another advantage of these rail motor cars is that it is possible to arrange for

*

stops at points where sufficient population exists but where traffic is too small to justify the erection of a station of the ordinary type. For rail motor cars it is sufficient to erect a small wooden platform, similar to figure 17 in the report.

The results obtained by the Great Western Railway with rail motor cars prove that they provide a means of cheap and efficient transport on lines of secondary importance, the traffic of which is not large enough to warrant the use of complete trains with separate engines.

As regards the cost of working these rail motor cars, the results obtained by the Great Western Railway shew that these work out at from 7*d*. to 8*d*. per car-mile (45 to 51 centimes per car-kilometre), which is about one half the cost of working an ordinary train. From appendix *B* of the report, where the replies of the different companies to the question of cost are given, it will be seen that this varies considerably in different parts of the world; owing to the different methods of preparing accounts it is impossible to make an exact comparison.

In cases where outlying districts of some importance have required to be brought into more direct contact with the railway, the motor omnibus has proved to be the most useful means of accomplishing the desired end.

The Great Western Railway use road motor cars on twenty-nine routes, and carry passengers, luggage and goods. One hundred and twelve vehicles of different types are used. Appendix *C* gives details together with illustrations of the different types of cars belonging to this railway company.

Running in connection with the nearest railway station, these cars often prove that it is only necessary to adopt this form of transport to assure rapid growth and prosperity to the district served. These services naturally result in an increase of traffic on the railways running them. They are also of great importance in agricultural districts as they enable farmers to transport their produce rapidly and surely to the markets of the towns.

The superior speed of the motor car has enabled small places to be brought into closer touch with important centres, so as to stimulate the traffic between the two points and bring about the development of the small towns. In appendix *C*, statistical information is given shewing how quickly these motor service have developed as feeders to the Great Western Railway.

In regard to the cost of working, this varies with the nature of the route covered and the type of vehicle used. Speaking generally, however, it has been found by the Great Western Railway that it is about 9·94*d*. per mile (64 centimes per kilometre).

The value of these road motor cars depends entirely on the quantity of traffic necessary to justify their introduction. They are used largely for the purposes of collection and delivery of traffic. Compared with horsed vehicles, road motor cars shew the three following advantages as shewn on page 8 of the report (1):

1° Quicker delivery to points at the extremities of the collection and delivery area, and extension of such area;

2° Possibility of dealing with exceptional traffic without necessitating an in-

(1) Vide *Bulletin of the Railway Congress*, number of December, 1909, p. 1741.

crease in the number of cars. The motor car can when necessary work double shifts, without excessive strain;

3° The employment of fast vehicles for the long distances relieves the horses, which can give a better service for short distance traffic, where the motor cost would be higher on account of the short mileage.

The Great Western Railway has obtained the best results, so far as town service is concerned, with a small motor van of 16 to 20 horse power with a loading capacity of 15 cwts. and a maximum speed of 20 miles per hour. The working cost of this van comes out at about £4.12*s*. for a weekly run of 300 miles.

I would add that the replies the reporter has received from other companies on the subject of the use of motor cars for services of collection and delivery are very brief and of little use. It would seem that other railways have not interested themselves in this means of transport so much as the Great Western Railway. Those who have experimented with motor traction appear to have obtained less satisfactory results, due I believe, to their types being too large and heavy and also to the motor vehicle not having been employed to the best advantage; that is, it is used on the same routes as the old horsed vehicles, when it would be more advantageously employed, especially the smaller type, on other and longer routes.

For myself, I am convinced that this means of transport, especially the smaller type, will be more extensively used in future. I feel sure that if sufficient loads and mileage can be obtained for them, motor vans of the type mentioned in the report and illustrated in the photographs have a great future before them.

The President. (In French.) — Before beginning the discussion of motor-car services, I wish to inform the meeting that the question of motor vehicles running on rails has already been discussed at length by the 2nd, 3rd and 5th sections, meeting jointly; and they adopted the following conclusions :

1° Automotor cars can be used in certain cases for economic services, in order to facilitate local communication at a moderate outlay, provided that the traffic conditions lend themselves to the organization of trains, carrying a regular traffic or at least one which only varies rarely and but little, that the line is an easy one and that the goods traffic can be carried conveniently and completely on separate trains;

2° The power of the motors of the automotor cars should present a certain margin beyond the ordinary work, so that it is possible to cope with variations of the traffic within certain ascertained limits;

3° It would be desirable to make it possible to utilize the car independently of the motor by having either separate motor trucks, or some other device making it possible to remove and replace the mechanical part easily;

4° From the point of view of economy of staff, that is to say, having only one traction agent, accumulator or petrol cars seem the most suitable. It would be desirable that the investigations should be continued in order to ensure simple design and easy and inexpensive maintenance;

5° As regards steam cars, it would be desirable to reduce to a minimum the care required for the boiler and in particular to improve the semi-automatic feeding of the grate or to improve the methods of using liquid fuel;

6° It would be desirable to recommend the investigation of small locomotives able to replace automotor cars, with the advantage of greater independence. The luggage-van

locomotives, or the motor luggage-vans, represent an immediate solution, which it seems can be suitably applied in certain cases.

It seems that after such a full discussion and after such detailed conclusions have been adopted, we can hardly take up this subject again; and what we have to consider is the question of motor cars running on highways either for connecting up places not reached by the railway or for cartage purposes.

Mr. Guerreiro, *vice-president*. (In French.) — In the first place, I wish to commend the report of our colleague Mr. Inglis, concerning road motor cars.

Owing to the reasons just given by the President, the question of rail motor cars cannot come before us, as it has already been discussed by three other sections. We must accordingly limit ourselves to the subject of road motor cars, which is, moreover, of great interest; and Mr. Inglis was more competent than anybody else to deal with this here.

In his report he gives a summary of all the information he has obtained from the different companies, and above all from that which he himself manages and which has such well-organized services.

He has not drafted any conclusions, but at the beginning of his report he sets forth the advantages of motor car services and I propose to you that we should consider that part of his report as conclusions. I merely give you the wording :

" The Railway Congress recognizes that it has become of importance to railway companies to make the necessary provision for the transport of passengers and merchandise in the case of increasingly smaller distances and increasingly smaller quantities, in order :

" *a*) To hold their own against tramway and other similar competition;

" *b*) To develop new districts;

" *c*) To secure additional revenue."

To this I add another clause as follows :

" *d*) To operate the postal service."

You know that on the Continent the postal service is operated by the railways; and therefore I think it necessary to add the clause to the conclusions.

That is the proposal I have the honour to submit to you.

Sir Chas. J. Owens, London & South Western Railway. — I will commence by thanking the reporter for the information with which he has furnished us on the subject of motor vehicles. With the two honourable members who have already spoken, I agree that the question which this section has to consider is more particularly that relating to road motors. I myself am especially familiar with goods working, and I have noticed that the capacity of transport by motor vehicle is not always proportional to the motive power. When motor vehicles contain heavy loads it frequently happens that the unloading takes two or three hours and during the whole of this time the motors are at a standstill, and earn nothing, whereas in the case of horse vehicles, the animals can be detached during the unloading and utilized in other ways. From this point of view therefore, motor traction is inferior to horse traction.

If the motor could be separated from the vehicle and used for another purpose, a great advantage in favour of motor traction would be gained. The London

& South Western Company has found this objection to be less in the case of the delivery of single packages than in the delivery of such consignments as occupy a considerable time. The question is far from complete elucidation and it is to be hoped that fresh light will be thrown upon it by discussion.

As concerns the transport of passengers by road motor vehicles, my company has organized three different services.

By the first service, passengers were carried to and from the New Forest, but at the end of a few months the service was abandoned as the company was put to a loss.

The second service was designed to serve a rural district. This likewise was not a financial success — in fact it put the company to a slight loss, but it was felt that the service should be continued since it brought certain indirect advantages which compensated the loss.

The third service has been established under very favourable conditions to connect two parallel lines of railway distant about 12 miles one from the other, and passing through a very frequented district.

This service has supplied an easy means of transit between the localities traversed and the two railway stations thus connected. The vehicles are largely used, are much liked by the residents, while the financial results have been satisfactory.

A point not mentioned by Mr. Inglis in his report, and one which is particularly interesting to me, is the lapse of time in which, in the opinion of the Great Western Company, it is necessary to scrap the vehicles.

I feel that if the working of a service of road motor vehicles is to be efficient, the vehicles should be scrapped in six years.

This mode of transit is still in its infancy. It requires to be perfected and simplified before it can give practical results and be put to more general use. I think it is a question for the future and that it might well figure in the programme of a future session of the Congress.

Mr. C. Peter Clark, Permanent Commission of the Congress. — In my capacity as reporter on question XII, I desire to contribute a few remarks on this subject.

Thirteen years ago I had charge of a railway steam motor which is still in existence.

This car was unpopular with the trainmen because of the decreased size of crew required. It also caused considerable track trouble because of the heavy weight on the engine end which weighed 35 tons (the total weight on eight wheels was 57 tons). It was, finally, withdrawn from service on that light track, as the extra track maintenance offset the saving in running expense.

I believe that the substitution of gasoline for coal is sure to make great improvements, as it is possible to obtain far greater tractive power with the same weight, or the same power with much less weight.

We are now building a number of these gasoline cars in the United States and in 1909 there were forty-five of them in service, some seating 105 passengers.

The General Electric Company has recently produced a similar car furnished with a gasoline driven dynamo which applies the electric power direct to the axles, so as to avoid the transmission by chain.

The company are now building twenty of these cars, a number of which have already been sold.

The railway with which I have been connected for some time was obliged to use terminals in the city of Buffalo belonging to other companies at a great expense, and consideration has been given to the plan of highway delivery by motor truck. There are a number of suitable motor trucks operating in that vicinity, some of which handle 10 tons at 5 miles an hour; some carry 8 tons and draw a trailer carrying 5 tons more.

These motor wagons run from 12 to 15 miles an hour and appear, when the distance to be covered is several miles, to be cheaper than horses.

Mr. Coventry. — Mr. Owens has spoken of the depreciation of motor cars and observed that this should be calculated on a term of six years. I can mention a case in which a vehicle has been in use for seven years and is still working and in good condition.

Mr. Harahan, Erie Railroad, United State. — The company which I represent owns two motor cars of the type described by Mr. Clark, which are used in replacing trains previously operated by steam. These motor cars are giving satisfaction generally, but in the use of them we have thoroughly developed the fact that the principal essential for their success is in the proper care in their maintenance. They should be located as near to shops as is practicable. They should have a man running them who is capable of operating machinery successfully so as to keep it in repair, otherwise they are liable to failure which is a source of much expense, not only in the cost of repairs but in the loss of business brought about by such irregularity.

So far as the use of automobiles in America, for the purposes which this discussion treats of, is concerned, our conditions are radically different compared with those in Europe. In America, the railroad companies, as a general rule, do not deliver freight to business houses or to private houses; the delivery of freight to the railroads by the consignor, and the delivery from the railroad to the consignee is effected generally by the consignor and consignee, respectively, or by independent trucking companies. However, the express companies in America perform a service somewhat similar to that which is herein discussed, they collecting and delivering with their own vehicles that character of merchandise which they transport. Their shipments, however, are transported exclusively on passenger trains or upon special trains which are run exclusively for express business, and which are of higher grade than even what is termed as fast freight trains. As a general proposition, however, the express companies deliver their business only in the larger towns, and make no attempt to gather freight in from the highways outside of the towns. So far as the United States is concerned, it is a fact that in the greater part of the country the highways are not capable of being used for the purpose of heavy motor cars at all seasons of the year on account of their bad condition. In the older part of the country where it was necessary to have highways before railroads were built, the highways compare favourably with those of other countries, but in the newer section of the country the highways are very bad, which fact is recognized by a sentiment which is growing in the country looking towards the

improvement of road conditions. In many places our railroads were really pioneers and often were built instead of highways, and now the effort in improving highways is to improve those acting as feeders to our railroads.

Mr. Bloch, Orleans Railway. (In French.) — Seeing the present state of the question of motor cars on roads, it would be inadvisable to adopt any conclusions; but it would be useful if everybody would give information about such services, so as to give the members of the Congress data on which to base their opinions.

With this object in view I am going, as my contribution, to tell you the results of the experiments made by the Orleans Company, as regards mountain services.

The company has organized three motor car services, on the central plateau where the network of railways is of very large mesh; these services connect up places which are 30, 40 and even 50 kilometres (18·6, 25 and even 31 miles) away from the railway.

They have now been running two or three years with satisfactory results; in summer of course, for in winter these mountain roads are deep in snow.

Thus we have a service from Aurillac to Entraygues *viâ* Mont Salvy; another from Aurillac to Mur de Barrez and a third from Neussargues to Pierreford *viâ* Ussel.

Those services are on very difficult roads, and this will give you some idea of them; the Entraygues service starts at a point 600 metres (1,968 feet) above sea-level; then it goes up to 800 (2,625 feet), then down again to 528 (1,732 feet) and then up again to 900 metres (2,953 feet).

Another service starts at a point 800 metres (2,625 feet) above sea-level, then goes down to 500 (1,640 feet) and then up again to 1,000 metres (3,280 feet).

The third starts at a point 600 metres (1,968 feet) above sea-level, and then goes up to 770 and to 900 metres (up to 2,526 and to 2,953 feet.

As regards the former services, which run on mediocre roads, it did not from the start seem possible to adopt cars of the English type, with rubber tires.

The cars used for these services run on iron tires; with such tires petrol motors are unsuitable because of the jolting, and accordingly Purrey steam cars were adopted.

These services have been running regularly during the last two or three years and there have been very few breakdowns.

Travellers are pleased, for we have saved two hours in a journey taking five hours.

We have compared the cost of these services with that of the Great Western Railway services and we arrived at 62 centimes per car-kilometre (9·58*d*. per car-mile), while the Great Western found 64 centimes per car-kilometre (9·89*d*. per car-mile). The staff expenditure is nearly the same, but what is curious is that the sum of the traction costs and tire costs is the same for both services.

As regards the average cost of passengers, it is much the same, about 10 centimes per kilometre (1·54*d*. per mile).

The experiment thus appears to be satisfactory, and the traffic is growing.

We have also organized some short-distance services, but these as a rule have failed because motor-car traction costs more than horse traction, without any compensating advantages, owing to the shortness of the runs.

In conclusion, I do not think that the question is ripe yet, and no definite solution can be drawn from the experiments hitherto made. That is why I have suggested to Mr. Guerreiro to tone down his conclusions a little and we have jointly agreed to propose the following conclusions :

" The Railway Congress recognizes that it is of interest to improve, by means of road motor car services, the relations between stations and places distant from the railways, thus facilitating the conveyance of passengers, and the transport of goods and of mails.

" The number of road motor car services is, however, at present still too limited, and the experiments made are not yet sufficiently advanced, to make it at present possible to draw any precise conclusions as to the establishment and operation of such services.

" The 4th section proposes that this question should be kept on the agenda for the next meeting of the Congress."

Mr. Balaban, Rumanian State Railway. (In French.) — It seems that the conclusions proposed apply more particularly to railways managed by companies, but I think that a reservation is necessary as regards railways operated by the State. Railway-transport enterprises have in view both public and private interests, but these two objects are not of equal importance to a State administration and to a company.

A State administration must in the first place consider the general interest; it must ask itself whether the enterprise it is going to start is made necessary by that interest. Where competition exists between different transport companies, it is advisable to leave private initiative a free hand. The State should not interfere, but there are exceptions to this rule, as for instance in the case mentioned by Mr. Bloch, when the roads are so difficult or so bad that no transport service exists.

In that case there is a local interest mixed up with the general interest, and this double interest compels the State to act, either by subsidizing certain private services, or by organizing a transport service, so as to stimulate private initiative. Although it is sometimes of interest to companies to start competition with other companies, yet that is not, in most cases, so with the State. I agree with Mr. Bloch when he says in his conclusions that the question is not ripe enough to enable us to adopt any very precise conclusions. I even think it would be as well to introduce a reservation and to say in the proposed conclusions that the Congress recognizes the advisability of improving road motor car services when the general interest requires this to be done.

Mr. Bloch. (In French.) — It would only be necessary to add a word to the first clause and say :

" The Railway Congress recognizes that it is of general interest to improve, by means of road motor car services, etc."

Mr. Balaban. (In French.) — That is no longer a reservation.

Mr. Piéron, French Northern Railway. (In French.) — I propose to say :

" The Congress recognizes the utility of improving, in the general interest, by means of road motor car services, etc."

The President. (In French.) — Before I put the conclusions to the vote, the section will perhaps be interested in receiving some information about a legal provision, in force in France, which affects the subject under discussion.

The French government, as you know, gives subsidies to the minor railways which we call "railways of local interest", concessions of which are granted by the departments who also give subsidies. These minor railways generally connect smaller places with the main railroads.

Some ten years ago, it was thought that expense out of proportion to the interets involved could be avoided by giving certain departments the opportunity of organizing motor car services instead of such minor railways. The authors of this proposal did not imagine that the motor car could replace the railway in places where the latter is useful. But they thought that the motor car could be very useful as a means of ascertaining what traffic there might be in any district, as the vehicles could readily be shifted elsewhere if the results led to the abandonment of the service, either if there was not sufficient traffic to justify its maintenance, or if on the contrary, the traffic developed sufficiently to make a railway necessary. The French government, in order to prevent the construction of an excessive number of minor railways, of doubtful advantage, had inserted a clause in that law, under which subsidies could be given to motor car services, at a period when the problem was not yet solved from the technical point of view, so as to show the parties interested that an economic solution could be offered to them, in the no doubt near future. The law was not much of a success; it only received one or two applications.

Last year the law reduced still further the obligations imposed on those services. It had been specified that they must be able to carry 10 tons; this amount was reduced to 2 tons. These facilities, plus the progress made in automobilism, seem to have led to some enterprises.

It does not, however, seem that there is any fear of motor car services competing with the railway, when it is a question of interconnecting places of minor importance; for even when helped by the State, private initiative shows but a moderate readiness to establish regular services in the country.

I will now put to the vote the conclusions proposed, together with Mr. Balaban's amendment. They run as follows :

" The Congress recognizes the utility of improving, in the general interest, the communications between railway stations and outlying districts, by means of road motor car services, so as to facilitate passenger, goods and mail traffic.

" The number of such road motor car services is, however, as yet too limited and the trials made have not yet advanced far enough to make it at present possible to draw any definite conclusions concerning the establishment and operation of such services.

" The Congress proposes to keep the question on the list of agenda for the next session of the Congress."

— Adopted.

*

DISCUSSION AT THE GENERAL MEETING

Meeting held on 14 July, 1910 (afternoon).

MR. P. WEISSENBACH, PRESIDENT, IN THE CHAIR.

GENERAL SECRETARY : MR. L. WEISSENBRUCH.

FIRST ASSISTANT GENERAL SECRETARY : MR. MÜRSET.

SECOND ASSISTANT GENERAL SECRETARY : DR. A. BONZON.

Mr. Bloch, *principal secretary of the 4th section*, read the

Report of the 4th section.

(See *Journal de la huitième session*, No. 7, p. 5.)

" In the absence of Mr. Inglis, Mr. COVENTRY (*Great Western Railway*) gave particulars of this subject.

" The report drawn up by Mr. Inglis included two parts : one concerning the rail motor cars, and in accordance with a suggestion made by the President, this special subject was discussed by the 2nd, 3rd and 5th sections at a joint meeting ; the other concerned road motor-car services and was discussed by the 4th section.

" In connection with the latter point, Mr. Inglis noted their utility for communication between railways and outlying districts, and described the interesting experiments carried out on the Great Western Railway with numerous and important services. He also recommended the use of light vans for parcels collection and delivery in towns,

" In the ensuing discussion, Mr. GUERREIRO (*Permanent Commission of the Congress*) proposed that the statements contained in the report itself should be adopted as conclusions; Sir Charles OWENS (*London & South Western Railway*) disputed the advantage of motor car road services, at least in the case of goods in large quantities, and thought that as regarded passenger services this was a question of kind depending on individual circumstances; Messrs. C. Peter CLARK (*Permanent Commission of the Congress*) and HARAHAN (*Erie Railroad*) considered more especially the case of motor cars on rails, foreign to the 4th section. Mr. Harahan however remarked that in the United States express companies attended to the collection and delivery of goods and that passenger motor car services on roads would be

impossible owing to the bad condition of roads generally, except in the eastern parts of the country. Mr. Bloch (*Orleans Railway*) gave an account of the road motor car services operated by the Orleans Railway Company in Auvergne, and of the results obtained, and thought that in the present state of knowledge the question had to remain an open one. He proposed to the section to adopt the conclusions accepted by Mr. Guerreiro in place of his own and which took Messrs. Balaban' (*Rumanian State Railway*) and Piéron's (*French Northern Railway*) observations into consideration.

" The President, before putting these to the vote, mentioned the nearly fruitless attempts so far made, by the French government, to establish such motor car services. After these remarks the 4th section then adopted the following conclusions."

The President. — The following are the

CONCLUSIONS.

" The Congress recognizes the utility " of improving, in the general interest, " the communications between railway " stations and outlying districts, by means " of road motor car services, so as to facilitate passenger, goods and mail traffic.

" The number of such road motor car " services is however as yet too limited " and the trials made have not yet advanced far enough to make it at present " possible to draw any definite conclusions concerning the establishment and " the operation of such services.

" The Congress proposes to keep the " question on the list of agenda for the " next session of the Congress."

— These conclusions were confirmed by the general meeting.

REPORT N° 1

(Countries using the English language

By J. M. CULP,
VICE-PRESIDENT, SOUTHERN RAILWAY.

INTRODUCTION.

It is of prime necessity that, in order that freight traffic of transportation lines shall be preserved and increased, all commodities transported shall be delivered at points of destination, or consumption, in as nearly perfect condition as may be practicable. But commodities forming the list of perishables are distinguished by the fact that practically the entire list contributes directly to the support, or amelioration, of human life, and it is of the very highest importance that this particular form of traffic shall be delivered to consumer with the least possible deterioration.

A disposition to full co-operation on the part of the producer must be assumed and relied upon. The highest state of perfection in the transportation of perishable property is wasted effort in the absence of proper preparation for its shipment, and proper facilities for its receipt and distribution at destination. The carrier has the same ground for expecting the profit-taking shipper of perishable freight to adequately prepare and deliver his goods for transportation, as exists in the case of the shipper of ordinary merchandise. Hence, the province of the carrier with relation to the duty of the shipper and receiver, in this respect, must be more suggestive than otherwise and will be so treated below.

*

As self-interest prompts the producer of perishable freight to provide the best methods to secure good condition of his property when delivered to the carrier, so the carrier is presumed to employ every ordinary precaution for receiving and transporting : *e. g.*, adequate loading platforms, preservation of cleanliness in cars by prohibiting their loading with deleterious freight, cleansing and testing of refrigeration apparatus, etc. This discussion will therefore deal mainly with the care of the property en route.

It is a safe assertion that intelligent experimentation in the handling of perishable freight has proceeded with all the carriers by rail to a degree commensurate with the difference between the requirements for handling such freight, and the requirements for handling ordinary property. With the increase of the non-producing population, has grown the necessity for commensurate increase and regularity of supply, which has been met no less in the cases of fresh meats, fruits and vegetables, than in the cases of building material, fuel, clothing and staple articles of food. Obviously, the volume of traffic in certain classes of perishable freight, which are more or less luxurious to the large mass of consumers will never equal the volume of traffic in staple articles of consumption : but carriers recognize the desirability of bringing producer and consumer together, and are sparing no proper effort to this end.

Barometric and thermal conditions are the chief factors to be reckoned with : variation as to these factors between the different countries of the world is sufficiently determined to warrant the general statement that a satisfactory transportation practice in one section can be safely adopted by other sections where the same barometric and thermal conditions prevail; therefore, the suggestions presented should be universally useful to carriers of perishable traffic.

Property susceptible to early deterioration and decay is properly subject to the following general classifications :

Products of animals. — Fresh meat, products of packing houses, or abattoirs.

Dairy products. — Butter, cheese, milk, dressed poultry, eggs.

Products of agriculture. — Highly perishable fruits and vegetables, ordinary perishable fruits and vegetables, tropical fruits.

Miscellaneous. — Fresh fish and sea foods, beer in kegs.

This general classification will be employed in the following discussion which will not permit of elaboration of each form of perishable freight.

Because of lack of more detailed information as to foreign practice, your Reporter is forced to discuss methods with respect to each of the classes of perishable freight, from the standpoint of prevailing American practice.

CHAPTER I.

The refrigerator car.

The invention, successful construction and adoption of the refrigerator car, or cold storage house on wheels, marks the first and furthest step toward the accomplishment of the carriers' duty with respect to perishables.

The preservation of food products en route is of greater importance than accelerated transportation, since it is clear the most rapid practicable handling will not, where long distances are to be traversed, prevent the development of deterioration. The multiplication of the ineradicable germs of fermentation and putrefaction is most effectively retarded by temperatures below 50° Fahr. Besides, as these germs develop more rapidly in a moist medium, the science of perfect refrigeration must reckon with the percentage of moisture, or humidity, in the surrounding atmosphere. A normal humidity is shown to be between 70 and 75 per cent saturation, and a safe general formula for efficient refrigeration may be stated thus :

Temperature between 32° and 40° Fahr.
Humidity 70° to 75°.

This formula presumes the application of cleanliness in the preparation of products to secure the maximum external sterility or asepticism.

Mr Bryce in his article, "Preservation of Foods by Cold" (*American Journal of Public Hygiene*, May, 1908), succinctly summarizes these fundamentals of refrigeration :

> The trinity of asepticism, cold, and a proper relative humidity is a sort of *e. pluribus unum*, which must in scientific cold storage be our object of reverence and worship.

The same writer in discussing the availability of cold storage obtained from ice, and from artificial means, asserts the necessity for a constant temperature, attended by a constant percentage of humidity and proves the desirability of mechanical refrigeration for cold storage warehouses. The refrigerator car attains the maximum of efficiency to date in regard to the necessities for cold storage applied in transit; it having so far appeared impracticable to adapt mechanical refrigeration to railway equipment in motion.

The standard American refrigerator car combines with facilities for refrigeration, facilities for movement under ventilation by the forced passage of outside air through the car by opening ice chambers and arranging hatches.

This facility of general use in countries of North America has also been adopted by the English-speaking Managements of Railways in the following countries : England, Australia, the Argentine.

It appears not to have been adopted by the English-speaking Managements of Railways in other countries assigned to your reporter. The following description of the refrigerator car in use on the North Eastern Railway of England, with diagram (fig. 1) is the only detailed data which has been furnished :

A covered wagon of 7 tons capacity fitted with Westinghouse and Vacuum Automatic brake and built to run at fast speeds — Fitted with ice cylinders carried through to the roof so that they can be filled without opening the wagon out — access to the roof by means of fixed step ladder. The wagon is air-tight, india-rubber piping being fitted round the doors for this purpose.

The roof is covered with 7/8 inch boards over-laid with canvas, and there is an interior ceiling of 1/2 inch boards with 2 inches of Silicate Cotton filling the space between. The sides and floor have also an interior and exterior lining of 7/8 inch boards with Silicate Cotton filling the space.

The wagon is zinc-fined, and the lining is easily cleaned by means of water and, where necessary, " Rocklight " cleansing fluid in the proportion of half a pint of fluid to each pail of water.

The wagon has eight cross bars holding 72 hooks inside for slinging beef or mutton carcasses.

No detailed description is furnished by Railway Managements of other countries, except diagram of car in use on Western Australian Government Railways (fig. 2).

A typical refrigerator car in North American service for the transportation of fresh meats is described as follows :

Refrigerator beef car.

General dimensions :

Capacity of car	60,000 lbs.
Length of car over end sills	36 feet.
Width of car over side sills	8 ft. 11 in.
Height of car between sills and plate	7 ft. 1 in.
Length of car between end linings	35 ft. 1 5/8 in.
Length of car between tank aprons	31 feet.
Width of car between linings	8 ft. 5/8 in.
Height of car between floor and ceiling	7 ft. 1 9/16 in.
Loading capacity in cubic feet	1,779.30 cubic feet.
Light weight of car	38,000 lbs.

Floor frame :

Side sills	5 × 9 inches.
Intermediate sills	5 × 9 —
Center sills	5 × 9 —
End sills (oak)	8 × 9 —
Needle beams (oak)	4 1/2 × 8 inches.

Standard double linofelt insulation.

Four ice tanks in each end of car, arranged as shown in diagram (fig. 3).

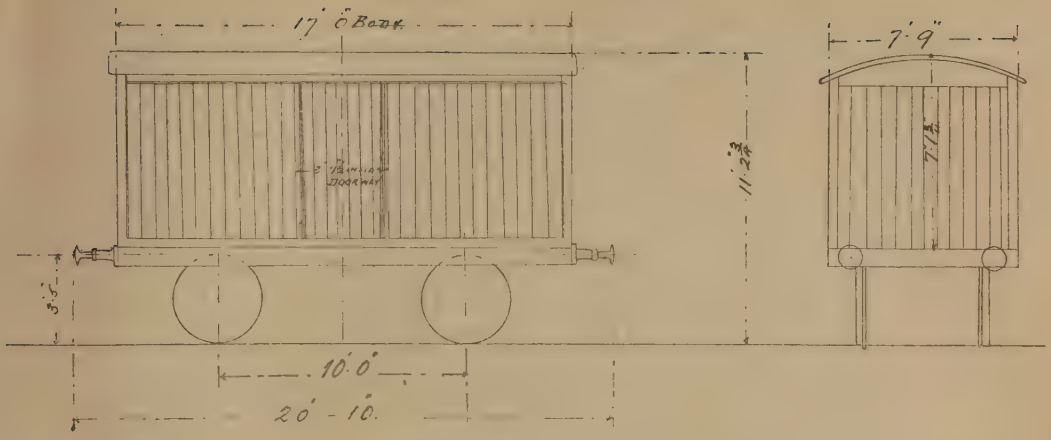

Fig. 1. — North Eastern of England. — Refrigerator van.

To carry 7 tons; tare 9 tons 9 cwt. 0 qrs. — Capacity 648 cubic feet.

The following describes a type of North American refrigerator car for handling perishables, other than fresh meats :

Refrigerator provision car.

General dimensions :

Capacity of car	60,000 lbs.
Length of car over end sills	38 ft. 8 in.
Width of car over side sills	9 feet.
Height of car between sill and plate	7 ft. 5 in.
Length of car between end linings	37 ft. 11 5/8 in.
Length of car between tank front linings	31 ft. 10 1/2 in.
Width of car between linings	8 ft. 2 5/8 in.
Height of car between floor and ceiling	7 ft. 5 15/16 in.
Loading capacity in cubic feet	1,980 cubic feet.
Light weight of car	38,000 lbs.

Floor frame :

Side sills	5 × 9 inches.
Intermediate sills	4 × 9 —
Center sills	4 1/2 × 9 inches.
End sills (oak)	6 × 9 inches.
Needle beams (oak)	4 × 8 —

Standard double linofelt insulation.

One ice box at each end of car, arranged as shown in diagram (fig. 4).

It should be borne in mind that while refrigerator cars, partially worn or not of the highest type, may be suitable for the preservation of certain types of perishables, they may not be suitable for other types of perishables. To illustrate : fruits and vegetables, permitting a somewhat wider range of temperatures inside the car during transit, may be successfully handled in refrigerator cars, which may have lost some of their original value in the beef trade. On the other hand, the refrigerator beef car is equipped with ceiling racks and hooks, and cannot, be economically employed in the fruit and vegetable trade.

The following table exhibits the carrying capacity of these three types, and displays a preponderance of dead weight in connection with the Western Australian and the American cars. This is accounted for, as to the American car, mainly by necessity for heavier construction, particularly in the underframe, to stand movement over long distances and widely varying surfaces, and consequent severe usage :

	Weight of car.	Capacity.	Total weight under load.	Percentage of dead weight.
North Eastern Railway of England	18,900 lbs.	14,000 lbs.	32,900 lbs.	59
Western Australian Railways	34,500 lbs.	16,000 lbs.	50,500 lbs.	68.31
Standard North American car	38,000 lbs.	60,000 lbs.	98,000 lbs.	63.33

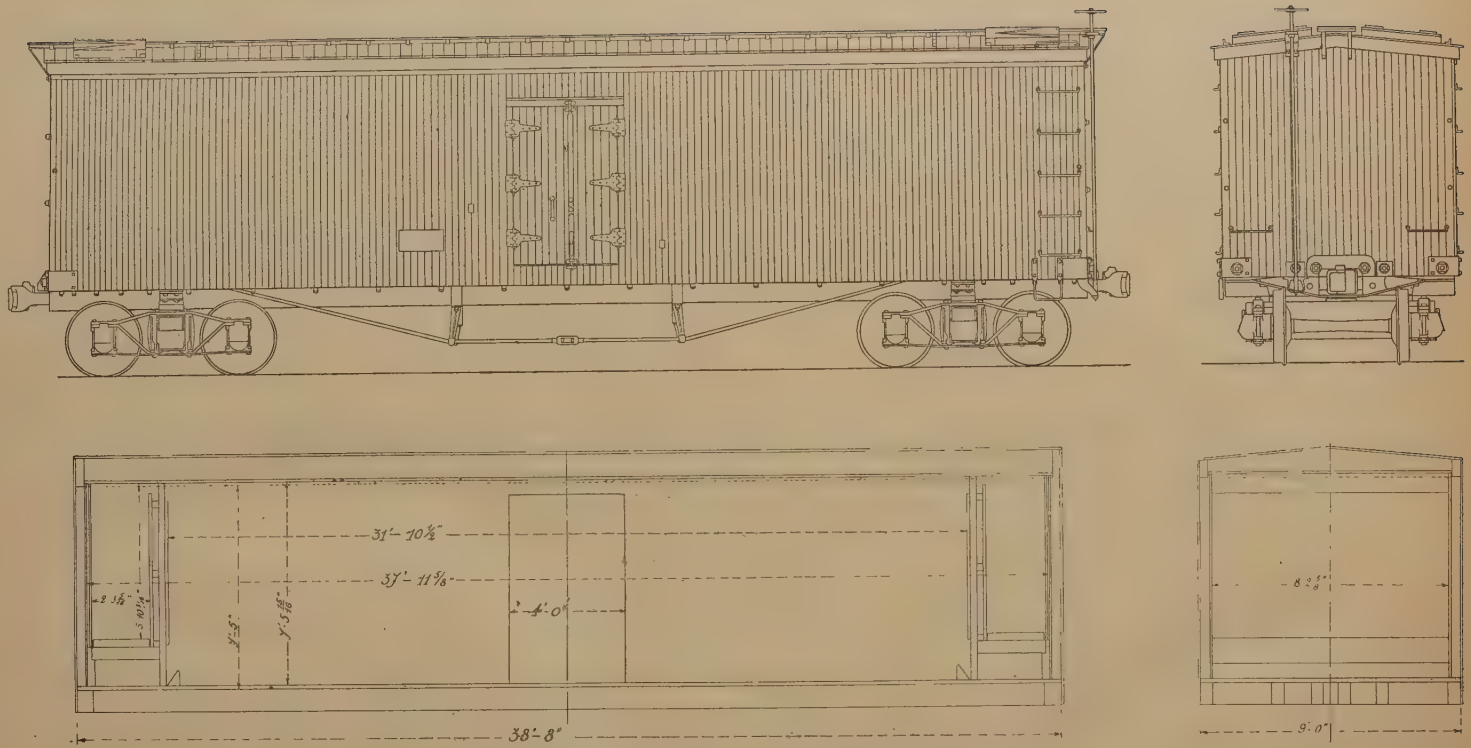

Fig. 4. — Diagram of R. F. 1. fruit car showing loading space.

It cannot be successfully contended that the American car sacrifices carrying capacity to improve refrigeration; experience has proved its adequacy and success in both respects.

The present American types of cars have been evolved from experiments beginning, according to the best authority, with the refrigerator car patented by William Davis, of Detroit, Mich., in 1868, although experiments had been, previous to that time, conducted by W. W. Chandler, an official of the Pennsylvania Railroad, in connection with box cars with double sides, roof, and floor, insulated with sawdust, and iced by the insertion of a box of ice in the door of the car, after it had received its loading. Both of these experiments were directed to successful transportation of dairy products and fresh meats.

The Davis Car is described by D. W. Davis, the son of the inventor, as follows:

The shed of the car is constructed with a dead air space entirely around the top, bottom, sides and ends of the car. On the interior are placed layers of hair felt, two inches in thickness, and this is again lined with an interior wooden shell. This construction makes a non radiating and non-conducting wall of great power to resist the action of external heat and renders the expenditure of ice quite small to maintain the required depression of temperature after the interior of the car and its contents have been cooled down to the proper point, say from 54° to 58° Fahr. Along the sides of the car are placed galvanized iron tanks, which extend from within one inch of the top of the car to within three inches of the floor. These tanks are 4 1/2 inches wide at the top, and taper (wedge shape) to 2 inches wide at the bottom. The tanks communicate at the top with funnel or hopper-shaped openings fitted with tight plugs, and at the bottom through drip pipes, with proper traps which carry away the drippings. The funnel shaped openings on top are used for putting in the refrigerating mixture, consisting of broken ice and salt. The tanks, or ice receptacles, are so placed in the car as to allow free circulation except on the ends, which are closed up.

In operation, the ice receptacles are charged with ice and salt — about ten pounds of salt to one hundred pounds of ice — which reduces the temperature of the surface of the iron below the freezing point; the narrow space between the ice receptacle and the wall being much cooler than the chamber of the car, the cold air drops down of its own gravity, passing out underneath the receptacles into the body of the car. By this circulation of the air, all the warm air and all vapors from the meats, fruits and vegetables are automatically drawn over the top, and, coming in contact with the iron that is below freezing point, the moisture of the air is deposited on the walls of the receptacles in the shape of hoar frost, thereby purifying the air as it descends, and, as it passes into the chamber, it is ready to take on another load of moisture.

A refrigerator built on this plan can be regulated to any degree required, either above or below the freezing point, by the quantity of salt that is used on the ice; the current of cold dry air is maintained without the introduction of external air. The air is perfectly dry, as all moisture is frozen out.

This car was built primarily for the transportation of fish, in which the firm of Davis & Company was largely interested, and its adaptation to the dressed beef business was undertaken by Mr. Geo. H. Hammond, of the firm of Hammond-Stan-

dish & Co., of Detroit, Mich.; the first shipment of beef in these cars being made and accompanied by Mr. Hammond sometime during the year 1869.

There have been numerous patents for improvements on the general theory underlying the Davis Car; notably the Wickes and Tiffany patents, which are described by *Ice and Refrigeration* (Chicago and New York, November, 1901, vol. 21, No. 5, p. 207) as follows :

In 1877 two patents were issued for the construction of refrigerator cars, which afterward became the basis of what were designated systems. Patent No. 189,001 was issued to James H. Wickes on March 27th of that year; his plan was to place the ice tank at one end of the car adjoining the provision chamber, and at the other end was an air chamber, which connected under the ceiling with the provision room. This air chamber extended across the full width of the car, down the end and under the floor to a fan blower in the center. The fan (which was operated by a power attachment from the axle of the car when the latter was in motion, or by hand when it is at rest) drew the air from the provision chamber through the air space and ice tank, whence it escaped at the bottom, and was distributed across the width of the car into the provision chamber. As the water accumulated from the meltage of the ice it raised an automatic float valve, and the surplus water escaped without admitting the outside air.

On 24 July, 1877, patent No. 195,557 was issued to Joel Tiffany, of Chicago, the ice in his car being located in a tank placed above the roof in a separate compartment. The under side of the galvanized iron tank formed the roof of the provision chamber. Outside air is admitted through horizontal air passages, which have openings at the corners of the car. In cold weather these openings were to be closed with stoppers. Tubes connected the provision chamber with the air space, permitting the escape of foul air. At each end of the compartment, or story, containing the ice tank was an opening for the outer air to enter, provided with a regulating valve and shutter. The air passed down into car through pipes to the water tank containing the melted ice. A wire screen kept out the cinders, while the water over which the air was drawn absorbed the dust, The air was then carried by pipes to the ice tank, the ice resting directly on the pipes, and distributed when cooled by smaller pipes, running lengthwise of the car. Refrigeration and circulation were thus accomplished entirely by automatic methods. Such devices as the fan blower being rejected.

The Davis theory was adopted by Armour & Company on account of its simplicity, and its evolution has produced the Hamilton Car, in which the insulation is obtained by construction combining wood, air space and hair felt; the roof, walls and bottom of the car being 7 inches in thickness, with the dead air space, and three 1 inch layers of hair felt. The joints of the doors are padded to make them air-tight when closed. The ice receptacles are simply strong galvanized iron cans, four of which will fill each end of the car. These extend from the roof to within six or eight inches ot the floor, and under them is a pan to catch the drip, the over-flow escaping through an air-tight trap.

The ice is loaded through the roof, being crushed into small pieces and mixed with fine rock salt. The cans are then filled (each car holding about 6,500 pounds

of ice) and the covers are put on and closed. No air enters the car and there is no provision for mechanical circulation of air within the cooling chamber.

After the cans are thus filled with crushed ice and salt the car is allowed to stand for some twenty-hours, the temperature within being reduced to about 33° Fahr. The car is then re-iced about 1,000 pounds being usually required for this purpose), and is then run into the cooling room of the packing house to receive its load of meat. The temperature of the car and cooling room is practically the same.

No improvement effected by carriers — not excluding quicker schedules — has produced such economic results as the refrigerator car. The present fresh meat, fruit and vegetable industries represented in America by millions of dollars investment, and affecting thousands of square miles of territory, are almost entirely the product of this device. It is quite conceivable that if cars containing perishables moving over long distances could be kept constantly in motion and not be stopped, even for a short time, at terminal points of the intermediate roads making up a through route, ventilated cars might in many cases be substituted for refrigerator cars; but the inevitable stops en route at intermediate terminal points make such substitution unsafe. As the production and distribution of fresh meats have evolved the past thirty years from strictly local distribution, or the less economical transportation of live-stock over long distances, into a national wealth reaching into the millions : so the traffic from fruit and vegetable growing districts — in many cases previously undeveloped in this character of traffic — has brought wealth to wide areas, and thousands of individuals. The following tables and statistical data show results to producers, and give evidence of growth in volume of carriers' business :

Slaughtering of Cattle and Hogs.

Report of United States Commissioner of Corporations, on the beef industry, 3 March, 1905.

1880	8,305,894 carcasses.
1890	15,070,809 —
1900	24,084,265 —

Statistics showing actual movement of fresh meat and packing house products under refrigeration have not been obtainable in carloads. However, the above table indicating the total slaughterings at principal slaughtering points, taken in connection with the statement of a competent authority that all shipments of cattle and hogs are made in refrigerator cars, quite clearly indicates the growth of the industry, and the traffic created thereby, a result founded upon the use of the refrigerator car.

The following table shows the movement of fruit in years when there was no failure of crop, total or partial, commencing with the earliest year for which a record was kept.

This development is made possible by the use of the refrigerator car, and reflects growth of an industry from, primarily, one County to a large portion of the State,

bringing hundreds of thousands of dollars added revenue to the producer and carrier.

Movement of citrus fruits from California.

(California Fruit Grower, 22 December 1906).

Date.	Carloads.	Percentage under refrigeration.	Date.	Carloads.	Percentage under refrigeration.
1894-95.	5,575	...	1900-01.	24,900	47 per cent.

1893	250	1904	4,800
1895	743	1908	5,000 (approximate).

Movement of Strawberries.

The strawberry, owing to its extremely perishable nature, cannot be transported in carload lots over long distances, except under refrigeration, and the following figures furnished by a carrier in the South-Eastern section of the United States, whose territory is adapted to strawberry culture, show how quickly and effectively the culture af the strawberry has responded to the use of refrigeration methods by the carrier in question : the diminution in the movement during the years 1907 and 1908 is due entirely to partial or total failure of crop :

Date.	Carloads.	Date.	Carloads.
1897.	425	1903.	1,975
1898.	675	1904.	2,109
1899.	950	1905.	2,022
1900.	1,100	1906.	2,613
1901.	1,150	1907.	907
1902.	1,220	1908.	1,095

Early Vegetables.

The traffic in vegetables has been so diversified as to preclude an exhibit for each type. It has not been confined to refrigerator cars, but as to certain varieties of vegetables, ventilated cars have been largely employed. Furthermore, it has been found difficult and burdensome for carriers to compile aggregate tonnage for a period of years. However, there has been a development of this traffic in the tide water districts of Virginia, the Carolinas and Georgia, the entire State of Florida, and the States of Alabama, Mississippi, Louisiana, Texas, Arkansas, Tennessee and Southern Illinois, the volume and importance of which is illustrated by the following figures for the years 1906, 1907 and 1908, furnished by one of the largest and most successful carriers of vegetables operating from a section of this territory of average productiveness :

Freight Receipts.	Tonnage.	Revenue.
1906	332,248 tons	$ 1,019,662·04
1907	467,179 —	$ 1,327,280·93
1908	365,583 —	$ 976,223·94

Cantaloupes.

On this important branch of perishable traffic, Mr. L. D. H. Weld, Garth Fellow in Political Economy, Columbia University, New York City, in his treatise, *Private Freight Cars and American railways*, says :

The Rockyford cantaloupe was first grown for markets at Rockyford, in the south eastern part of Colorado in 1885... In 1894 the growers co-operated and shipped for the first time in carload lots. Transportation facilities were not adequate for the handling of the crop, and the adjacent markets were flooded with melons with consequent loss to the farmers. It was not until 1897 that shipments were made as far East as New York by means of the refrigerator car... In 1897, there were one hundred and twenty-one cars shipped from the Rockyford District, in 1904, the number had increased to one thousand, one hundred and eighty-two... Prior to 1897, the high prices and limited supply made the cantaloupe a great luxury... New York had been supplied for years with an inferior melon... when the superior qualities of the Rockyford became known, other districts all over the country began to raise it — principally Carolinas, Florida, Georgia, Texas and California... The cantaloupe is a highly perishable commodity, and requires careful handling and supervision in transportation. It thus furnished, perhaps, one ot the most striking examples of the change that has been wrought by the refrigerator car on our agricultural development. In 1897 the amount consumed in the United States was not over 400 carloads : this amount gradually increased, until during the year 1905, 6,920 carloads were used throughout the country, and the season for cantaloupes has changed from a period of less than two months to six months of carload business.

An obvious effect of extended production, supplemented by cold storage and refrigeration-in-transit, is stability of supply, and increasing efficiency of organiza-

tion for marketing has brought about a scale of prices for products, at once profitable to producer, and attractive to consumer. It must be apparent that the credit for this result is largely due to refrigeration-in-transit, to the benefit of the carriers who have installed this refrigeration service.

CHAPTER II.

Practice of English-speaking Managements other than North America.

Responses to inquiries transmitted through the General Secretary of the Congress have been received from the English-speaking managements of railways in the following countries : The Argentine, England, India, South Africa, Australia, Mexico.

A brief description of the practice in handling perishable freight in the respective countries as indicated in these replies, follows :

THE ARGENTINE.

The outside temperatures are characteristic of the Temperate Zone, without excessive heat or cold, except that excessive heat is experienced in the Northern Provinces. It is not found necessary to adopt facilities to modify the natural temperature, with the exception of milk, butter and fish. Milk and butter are transported in cars or wagons, different from ordinary goods wagons only in the fact that they are lined inside with wood and provided with amianthe or other uninflammable stuff in the intervening space between the inside and outside walls. The only refrigeration used is ice which is placed in the wagons or around the tin packages. Fish is transported in boxes packed with ice, either ordinary cars or the above described equipment being used. All equipment is owned outright by the railways, and cold storage, pre-cooling, or other facilities supplied entirely by and at the expense of the shipper. Movement takes place over short distances, and existing equipment is felt to be adequate : no information furnished as to measure of refrigeration charges, method of stowage, or rules for general conduct of perishable business.

ENGLAND.

Temperatures ranging between 20° and 88° Fahr., with relatively short distance movement and high speed trains have greatly modified the necessity for specializing the handling of perishable freight. Although each of the respondent managements reports that perishables originate to some extent on their lines, the need for special

facilities appears mainly in connection with imports. But a relatively small part of the perishable list requires refrigeration-in-transit-which in accomplished by the type of refrigerator car described herein (fig. 1). Other wagons for handling perishable freight are designated as :

Insulated.

A covered wagon of 7 tons carrying capacity built on the same lines as the refrigerator, but without ice cylinders.

Hooded Perishable.

A covered wagon of 5 tons carrying capacity, fitted with Westinghouse and Vacuum Automatic brake and built to run at fast speed. The roof is covered with a single course of 1 ¼ inch boards over-laid with canvas. The sides and ends are doubled cased with air space between, and the floor is of heavy planking in a single thickness.

This wagon is provided with 8 cross bars holding 72 hooks and is ventilated by means of louvres there being six louvres at each side (two at top and one at bottom of wagon at each side of doors) and two at each end (one each at top and bottom). The top end ventilators are fitted outside with a projecting wooden hood which to some extent prevents the entrance of dust, etc., and the bottom end ventilators are fitted, *inside* the wagon, with a drop door which can be let down when less ventilation is required.

Whilst admitting air, these ventilators are also liable to admit grit and soot, and, to prevent this as far as possible, the wagon has two sheets of perforated zinc inside each louvre (one fine and one coarse mesh) and in addition to this some of the wagons have a layer of very fine copper gauze between the two zincs.

Even this was not found to be sufficient protection from soot and grit in the case of fresh mutton carcasses loaded direct from the slaughterhouse, often whilst hot, and always without wrappers, and the wagon is now fitted with screw studs round each louvre to enable it to take a "Blind Protector". This appliance was suggested and designed as the result of continued claims for dirty mutton and after full consideration of various methods of preventing the entrance of soot and grit, and, at the same time, admitting sufficient air. The "blind" is made of a sort of horse cloth American leather, the rough surface being next to the louvre where it catches and holds the flying dirt, whilst the leather surface, which is easily washed, faces the interior of the wagon. The rough surface is brushed at the receiving end before the blinds are returned to sending station for further use.

Since the use of this blind, there has been no complaint of dirty meat where the blinds have been used.

Perishable.

Same as the hooded perishable but not provided with the hood and drop door in connection with the end ventilators, and the studs for the blind protectors. When wagons are required for mutton carcasses, the hooded type are supplied.

Meat.

A covered wagon of 8 tons carrying capacity, built to run at fast speeds; fitted with the Westinghouse and Vacuum through pipe.

Has six louvre ventilators; four at sides (one at bottom of wagon each side of doors) and two at ends (bottom).

Fish (covered).

A covered wagon of 10 tons carrying capacity, built to run at fast speeds, and fitted with Vacuum Automatic brake and Westinghouse through pipe.

The wagon is ventilated by means of four louvres at the top of the wagon sides (two at each side), placed at either side of the wagon door, which doors slide instead of opening outward or dropping.

The wagon is lead lined for three feet up the side and is fitted with shelves at each end for the conveyance of *dry* fish.

Some of this type have the floor boards covered wit " Adamant and Asphalt " paving, whilst the sides are lined with sheet zinc giving a sanitary and easily cleansed interior.

The major portion of the *wet* fish in carried in kits, but for dealing with bulk fish, doors, which can be slotted to make the wagons more or less of a tank, are provided.

Fish (open).

An open wagon of five tons carrying capacity built to run at fast speeds and fitted with Westinghouse and Vacuum Automatic brake.

The wagon has latticed sides and sliding doors. 50 of this type are lead lined.

Strawberries and Gooseberries are transported in wagons fitted with shelves sloping to sides and ends, which wagons when not employed in horticultural traffic are used for import cheese.

Milk is transported by passenger trains in specially designed wagons or vans, characteristic type of which is 32 feet long with eight tons carrying capacity, the essential feature of which is ventilated sides, lined with zinc from the floor up to a distance of three feet (fig. 5).

All equipment is owned directly by individual carriers, and refrigeration charges are usually included in the conveyance rates.

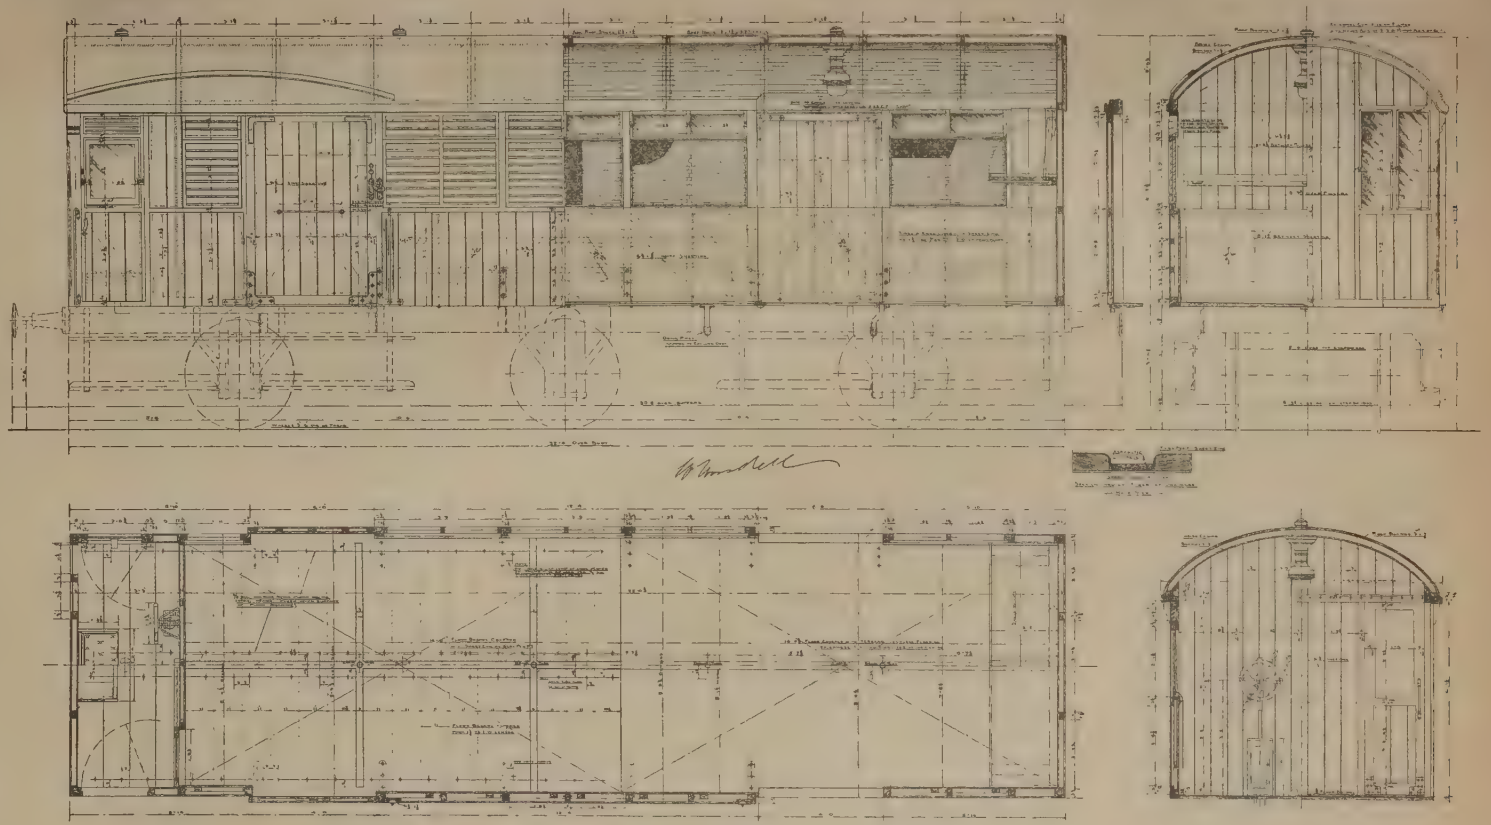

Fig. 5. — North Eastern Railway of England. — Body for 32 ft. 0 in. milk vans.

Tare 14 t. 2 c 0 q. — To carry 8 tons.

All cold storage or pre-cooling facilities are owned and operated by shippers. The present facilities appear to be adequate for all existing requirements.

No suggestions are offered by respondents looking to improvements for the increase of traffic.

As English Railway Managements apparently rely mainly on rapid transit for the successful handling of perishable traffic, the following regulations of the North Eastern Railway for the consist of " Braked Freight Trains " are pertinent :

Braked freight trains.

1° These regulations refer to trains which are signalled by " Is line clear? " signal; 5 consecutively, and also to fish and meat trains from Scotland, which are signalled 4 consecutively.

2° For the purpose of calculating the number of braked vehicles of which the train is to be composed the following table must be observed :

Engine counts as	3	vehicles.
Tender counts as	2	—
Tank engine counts as	3	—
— or six wheeled vehicle	1	—
8 wheeled bogie	2	—

3° These equivalents differ from those given above which are for passenger trains only;

4° Braked freight trains are divided into the four following classes :

Freight trains booked at over 45 miles per hour average (class 1).

This train must be composed of vehicles built on coaching stock lines, tight coupled and piped throughout. If the van is piped but unbraked, the next vehicle within it must be braked.

Freight trains booked up to 45 miles per hour average (class 2).

These trains must be tight coupled. The whole of the vehicles need not be braked, or piped, but in other respects they must comply with coaching stock requirements. Unpiped vehicles in all cases to be in the rear next within the van.

Freight trains booked up to 40 miles per hour average (class 3).

These trains must be tight coupled, and have long buffers, oil boxes and 8 ft. 6 in. minimum wheel base. The springs must be secured to hangers or be bolted. (This includes springs bolted to axle-box or to the shoes.)

Freight trains booked up to 35 miles per hour average (class 4).

The trains must be composed of tight coupled wagons with their springs secured to hangers or bolted, except that not more than two slack coupled wagons may be placed in the rear within the van, provided their gross weight does not exceed 30 tons. (This includes springs bolted to axle-box or to the shoes.)

INDIA.

From replies received, perishable traffic is restricted to fruits, vegetables, dairy products and fish. All perishables are now handled in vans only, and without refrigeration, except in the case of fish, which are packed in ice by shipper. The following quotation from the Secretary of the Indian Peninsula Railway to the Acting Director of Agriculture at Poona, dated Bombay, 16 November, 1907, seems to present the attitude of the Indian Railways toward the adoption of special cold storage wagons :

" As regards the provision of cold storage vans, this Company has not so far constructed any such vans, as there have been no demands for them, and I think it would be accepted that it would not be sound policy to construct such vans unless there is a reasonable chance of their being regularly used. Cold storage is not a cheap means of transit, and it is doubtful whether, if constructed, there would be a demand for the vehicle. However, if the Chamber of Commerce will enter into more details and show where such vans could be used with financial success, this administration will be prepared to consider the matter further. "

It should be stated, the above quotation is a reply to an opinion expressed by the Chamber of Commerce, Bombay, that the development of vegetable and garden produce traffic might be obtained if steps were taken in the direction of :

1° Organizing more rapid system of transit;
2° Construction of cold storage wagons.

The Managements of Indian Railways unquestionably feel that with the present demands their traffic in perishables does not require the use of other than ventilated vans or wagons handled in passenger train schedules : a conclusion which your Reporter must assume to be sound, although it is proper for him to call attention to the results which have been attained under American practice from the quick and satisfactory delivery of reasonably fresh fruits and vegetables in large consuming centers. In India, the principal centers of distribution for perishable products appear to be the ports where there is to be served not only a large non-producing local population but an export trade which might be promoted to adjacent foreign countries, China, Australia, etc., not possessing, in all probability, the same variety of fruit and vegetable production as may be found in the Indian Peninsula.

From demonstrated results in other sections of the civilized world, it may be found by the Managements of Indian Railways in the fruit and vegetable traffic a fertile opportunity, not only for increasing their own revenues, but for stimulating the production of a variety of food products lessening the disastrous effects upon the people, resulting from the occasional failure of any one of the crops now grown. In the absence of comparative statistics, your Reporter is unable to form an opinion of the progressive development by the Indian Railways, but the present existence of traffic in both directions argues that the subject has already received practical and effective consideration.

SOUTH AFRICA.

The perishable traffic of South Africa does not differ substantially from the list given at the outset. Refrigerator or brine-cooled trucks are employed for the transportation of fresh meats and dairy products, ventilated equipment for the transportation of other perishables for distances up to one thousand miles; diagrams and detailed descriptions of these two classes of equipment have not been furnished. The existence of cold storage facilities under the ownership and control of shippers indicates the permanent establishment of the traffic in perishables, and that carriers are addressing themselves to its successful transportation.

The climatic conditions vary from sub-tropical to temperate in movement from tide water to considerable altitudes. Temperatures for the month of February, 1908, taken in brine-cooled trucks working between Mooi River (altitude, 4,556 feet) and Johannesburg (altitude, 5,735 feet) a distance of 357 miles, show fluctuation between starting point and destination, varying from a fall of 4° to a rise of 15° Fahr. The variation takes place between points whose outside maximum mean temperature varied by 10.4°, while the minimum mean temperature varied only 2.8°.

In other words, there was a tendency of the temperature inside the trucks to rise, while the tendency of the mean outside temperature was to fall. The nature of the load is not given and no opinion can be formed of the cause for this apparent discrepancy in variation between outside and inside temperatures. However, from the inside readings taken at an intermediate point which evidenced a tendency to depression in the inside temperature, the inference may be drawn that sufficient refrigeration was not supplied for the distance to be traversed and that refrigeration was not supplied at intermediate points. Replies indicate satisfaction on the part of the shipping agents, traders and receiving public, justifying conclusion that the subject is receiving attention at the hands of the Railway Managements to the end of fully developing the traffic.

AUSTRALIA.

Two respondents, The Western Australian Government Railway and New South Wales Government Railways, report the existence of a perishable traffic as described

at the outset, except eggs, butter and cheese, making the further statement that agricultural, and dairy farming are practically in their infancy. They further report a variation from 40° to 115° shaded temperature during the year, through the districts traversed, for the equalization of which refrigerated louvred vans are provided. A diagram of the refrigerator vans is furnished (see fig. 2). The louvred vans, the type of which is shown by diagram (fig. 6) is a metal construction and has a dead weight of 12,800 pounds, with a loading capacity of 15,000 pounds, with still another type also shown, of wood and metal construction (fig. 7), with a dead weight of 9,400 pounds, and with a carrying capacity of 12,000 pounds.

F.	4	15	2	5 tons.	Id. id.	99 1/2 id. id.	Id. id.	2	2
F.	4	14	0	5 tons.	Id. id.	94 1/2 id. id.	Id. id.	6	5

The Australian situation is unique, by reason of the encouragement being given by the Government through the provision of cold storage depots, which together with the provisions already made by the carrier presages a large growth of traffic in that territory. From the information furnished, it is observable furthermore that carriers, by concession in rates on fertilizer and manure, are stimulating production.

Private cold storage arrangements at point of shipment and destination, constitute an additional factor in the upbuilding of the business.

In the absence of more detailed information as to distance to be traversed, and

variations of temperature to be overcome, useful suggestions for improvements on the present practice applicable only to the Australian situation cannot be made.

MEXICO.

An interesting feature in perishable traffic in Mexico is the handling of pulque, a native vegetable liquor, which although subjected before shipment to a process of fermentation, is highly perishable. This traffic is transported in barrels in cars similar in construction to ordinary stock cars, and handled by special daily train service. The length of the haul on this product is not stated, nor any information given as to the schedules required to be maintained.

The practice and equipment for the handling of perishable freight in Mexico does not differ from that in the United States of America, although it is noticeable that the carriers only operate their own refrigerator equipment, and furnish icing at actual cost. It is stated that no free weight allowance is made for the ice, and under Mexican practice the shipper pays for the full load. Although the variation in temperature is from that of the Southern North temperate to that of the Northern torrid zone, the rise in the temperature over the distance traversed is not uniformly gradual, but is irregular, owing to the varying altitudes at intermediate localities. The chief protecting measure employed is prompt transportation, equipment in refrigerator cars being limited and generally used for the transportation of beer and ice. There would seem to be opportunities for increasing the production and carriage of perishable freight from Mexico, particularly for export, under the system successfully used in other territories.

CHAPTER III.

Fresh meats and products of packing houses.

In addition to fresh meat, the most important output of packing houses for domestic consumption are dried salted, and cured meats, and lard. The by-products, tinned and cannet meats, including sausage, butterine and beef extract, while demanding great care and attention to details of handling and shipping, are not so exacting as is traffic in bulk articles.

Fresh meats for distribution and consumption in North America require primarily a chilling process. Meats are not frozen, except in some cases for export movement over long distances, and also, where it is desired to preserve a supply of special goods for special consumers. The usual widely adopted process of chilling fresh beef is found to be satisfactory for shipping and holding for periods as long as sixty

days; the meat improving in quality during the first two weeks, remaining in most desirable condition for the next two weeks, when slow deterioration is likely to begin and continue for a period, varying with original quality, original refrigeration and conditions of refrigerators in which kept, up to probably six weeks from slaughtering. It is the aim of the packer, co-operating with the transportation line, to effect delivery under regular schedule and in regular quantities during the first four weeks after slaughter, which is done by maintaining temperatures in storage houses and in cars, according to the following table taken from *Compend of Mechanical Refrigeration and Engineering.*

(Seibel) :

Beef, fresh	37 to 39° Fahr.
Hogs	30 to 33° —
Livers	30° —
Mutton	32 to 36° —
Tenderloins, butts, ribs	30 to 35° —
Veal	32 to 36° —

Experts differ with the above author, prescribing temperature of 32 to 34° for beef.

Preservation by refrigeration of the different parts of the hog has received special study, resulting in the utilization of practically the entire animal. The prime factor is prompt refrigeration, and the maintenance of a standard circulation of dry cold air. The ribs, more fully described as the large cut which comes out of the back, containing the back-bone and about 2 $^1/_2$ inches of ribs, being the part from which pork-chops are taken, is the part of the animal demanding first and best attention. These ribs are boxed and covered with clear paraffin paper, and call for a temperature of 26 to 28° under conditions protecting against dampness or dripping on the boxes or the product.

The prevailing type of meat car is cooled by ice bunkers at each end of the car, which removes much of the danger of moisture precipitation on the ceiling and walls, but methods might be studied with profit, looking to the still further reduction of moisture percentage in the atmosphere of these cars, to effect satisfactory delivery of hog products, particularly the rib cut described above. Other highly perishable products of hogs, such as sausage and sweet pickled meats, are now handled in a manner procuring satisfactory results.

Modern practice prescribes as the primary requirement for satisfactory preservation, the complete expulsion of animal heat, to be accomplished as speedily as possible, after removal of the skin and evisceration and cleansing, but observing great care not to produce freezing of the outer tissues which results in the generation of internal decay, or " bone-stink ". The steady application of a temperature not below 30° and not exceeding 32° has been found to accomplish the best results.

Pre-cooling thus seems to be an absolute essential in the transportation of this product, and is furnished in every case by the producer or shipper. The duty then

remains to the transportation interests to assist in the maintenance of the desired temperature during the period of transportation. Except where re-icing is done en route, under the direct supervision of the shipper, the transportation line is required to provide facilities for re-icing, including not only ample supply of ice, but skilled attendance.

Figure 3, showing a typical refrigerator car for the transportation of beef, contains refrigerator tanks, four in number, circular in form, about 15 inches in diameter, at each end of the car, which are to be charged with a mixture of ice and salt : the ice crushed into pieces ranging from the size of a cocoa-nut to the size of a walnut, to permit close packing : the salt consisting of crushed rock salt, known to the trade as No. 3, with crystals the size of a hazel-nut, and smaller. The proper proportions of salt and ice necessarily form a very important part of the training of attendants : a successful formula being 90 per cent ice and 10 per cent salt. The resulting brine has a temperature often times under zero Fahrenheit, which shows some loss of refrigerating energy, but so far no means have been discovered to prevent this loss. It has been conclusively shown that the absolute requirement of a temperature in the handling of fresh meats of different kinds ranging from 28 to 34°, cannot be obtained without the use of salt. A fruitful field for investigation is open to transportation lines at this point, seeking to discover greater economy in the use of both ice and salt, without the loss of refrigerating energy referred to.

Experience so far, proves that varying the proportions of ice and salt will not accomplish the economy desired, because a much lower temperature is necessary in the contents of the tanks than is to be found in the body of the car. In order to preserve the low temperature necessary in the body of the car, the only variation in the mixture of ice and salt is determined by outside thermal conditions. The problem of utilizing the refrigerating energy wasted in the overflow brine, must find its solution in appliance for catching and holding this brine so distributed around the body of the car as to continue the action of refrigeration. Attempts have been made to accomplish this by utilizing a series of pipes, but in practice this method has been proven unsatisfactory because ice always contains more or less extraneous substances which clog the pipe. Experiments are being constantly made by experts in packing houses in this direction.

Provisions, that is, salted meats shipped in boxes or casks, as well as dry salted meats, require refrigeration in transit.

Siebel's figures being as follows :

Brined meats	35 to 40° Fahr.
Hams, ribs, shoulders (not brined)	30 to 35° —

Other authorities make these figures :

Brined meats (provisions as described above)	36 to 38° —
Dried salted meats (not brined)	38 to 40°

Carcasses prepared for shipment are cut in two quarters : each quarter suspended from a hook secured to a rack, fastened to the ceiling of the car. Small animals are likewise suspended. Under American practice each piece is covered with thin loosely woven cloth, which increases delivery in a cleanly condition. In stowing, particular care is observed to obtain density of load and thus prevent oscillation on suspended hooks as well as mutilation.

Allusion has been made to the fact in many instances the service of re-icing a car en route is rendered by branch establishments of the shipper, but where necessary for the transportation company to perform this service. it is necessary for specific instructions to be given looking to re-icing with salt in cases of fresh meat shipment, along the line of travel at each twenty-four to thirty-six hours distance : the frequency of this re-icing depending, of course, upon the outside temperature and seasonal changes.

Schedules for the transportation of fresh meat and packing house products are arranged with attention; first, to despatch, and it is not too much to claim that the maintenance of these schedules as now arranged under American practice is meeting immediate demands, although it is clear that further expedition in transfer of this property, particularly fresh beef and other meats, to effect delivery as early as possible during the period of progressive improvement in texture and food value — will still further stimulate consumption. This observation relates in a more pronounced way to long distance movements. Further progress may well be made along the line of securing regularity for these schedules, to secure deliveries on regular specified dates, against which the shipper and distributor arrange their stock, or supplies. Effort should be made to avoid delays en route resulting in accumulated deliveries which are disadvantageous to the retailer, who is thus forced to deal with a market one day bare of supplies and the next day over-stocked, and the temporarily stimulated consumption ultimately reduces the volume of traffic carried by the railroad, not only through loss of prestige as a carrier, but through the elimination of a regular uniform consumption, the most potent producer of an increasing volume of traffic.

The maintenance of regular schedules is in certain sections of the United States fairly well assured. Other territories are witnessing the improvement of facilities at terminals, the installation of double tracks, the purchase of additional rolling stock and the adoption of the most improved methods, generally, as they are developed, from time to time. In time, the carrier and the shippers will only have for solution the scientific questions of retarding shrinkage and deteriorated texture of chilled meat, permitting its longer retention in storage, as well as the opening up, through construction of new railroad lines, advertising arrangements, etc., of additional territories of consumption.

A subject to which the transportation lines should address themselves is the handling of cars sustaining injury in transit, suggestions for which have been made

by Mr. D. I. Davis of D. I. Davis & Co., packing house experts, Chicago, Ill., as follows :

Should a car be wrecked in transit, it is not wise to use the first car available marked "Refrigerator," and transfer the contents of the car to it. If the body of the car should have a hole broken in it, the "first aid to the injured" is to close the hole by blankets, quilts or similar means. Keep the car tightly closed, and allow contents to remain in it until a suitable beef car can be obtained. By a "beef" car is meant a refrigerator car that is used in this class of service by the patrons of the road. This car is provided with ceiling racks and hooks for the loading properly of beef. Be it always remembered that not all cars marked "Refrigerator" are suitable for fresh meat transportation. Those unsuitable are relegated to other service, after but a short life as a beef car.

It is of great consequence that any car before the load is transferred thereto, be properly pre-cooled. It will some times require twenty four hours to do this, but the car should be reduced at least to 36° before this transferring is attempted. The contents are a great deal less damaged if allowed to remain in the original car, even thirty-six hours if necessary. The cold stored in the 25,000 pounds of product loaded in the car is a reserve force which helps in these instances.

Another element in successful development of traffic in fresh meat is, of course, export trade, for which the present expeditious Trans-Atlantic service and cold storage compartments in steamships, have rendered available for foreign consumption the chilled meat of domestic production. The end to be obtained by inland carriers with respect to this trade is the appointed delivery to designated steamships and the most expeditious transfer of contents of refrigerator cars to vessels' cold storage rooms. The following quotation from Mr. Davis, briefly but clearly describes this method :

The transferring of the contents from the cars is usually done at night and as quickly as human ingenuity can devise means to do so. The beef and small animals are carried out of the cars, laid on rope nets covered with white canvas. These nets are hoisted by means of the ship's winches, lifted rapidly over the sides and lowered into the holds.

CHAPTER IV.

Dairy products, eggs, butter, cheese and milk.

Taking the list in inverse order :

Milk is probably the most highly perishable traffic offered to the carriers, and the first and practically the only requisite in transportation, according to the best methods in use in the United States, is quick and regular delivery to the consumer. For this reason, a large development in milk traffic over long distances will remain problematic, dependent upon discovery of effective and sanitary agencies to retard or destroy development of fermentation. The tendency of milk to " sour " quickly, has been overcome in some of the continental countries in Europe, by the process of freezing into blocks of ice, and shipping as milk-ice, methods being adopted to agitate the milk during the freezing process, thus providing for uniformity of substance throughout the frozen milk when delivered on the market. The practice in the United States, which has resulted in a very large traffic in the vicinity of consuming markets, such as New York, and Chicago, began under the best methods with the refrigeration, artificially, of the dairy. The description of this method is given in *Ice and Refrigeration*, volume 21, No. 4, October, 1901, page 126 :

> The milk, as it is brought in from the country, is first tested for quality. It is then placed in a large tin tank, from which it passes through three sets of fine silk strainers, which remove all the particles of dirt or dust that may have got into the cans. It then passes through a series of tin pipes, which are submerged in a large brine tank. The tank contains, of course, the ammonia expansion coil, by which the brine is kept at the required temperature. After passing through these coils, the milk is drawn off into cans, which, in turn, are stored in a large refrigerator, kept at a temperature of, say 35°.

Milk prepared by the dairy, as just described, is shipped in two forms of packages, namely, metallic cans and bottles, the metallic cans of 40 quarts capacity, and bottles conveyed in wooden cases partitioned to provide separate space for each bottle, with space between top of bottles and the top of wooden case to permit covering the bottles with ice.

The shipments in metallic cans, which do not permit of tiering in cars, are shipped without ice during cold weather. During warm weather the ice is placed around the shoulders of the cans. Bottled milk or cream is gathered up from station in less than carload quantities, and is iced during warm weather, by placing ice in the cases or carriers around the necks and mouths of the bottles.

The practice of the leading milk handling lines involves the operation of trains on regular schedules, and with passenger train speed : these trains being run on main trunk line for the handling of milk only, with mixed passenger and freight

train service on lateral or branch lines making connection at junction points with solid milk trains. The schedules on branch lines are arranged on basis of about 12 to 18 miles per hour. The main line train is operated with a schedule of about 20 to 25 miles per hour. These services have entended their scope from year to year until at the present time, milk is transported over distances of nearly 400 miles to New York City on a schedule which leaves the shipping point about 8 o'clock a. m. and reaches Jersey City for next morning's delivery at about 12 o'clock midnight. This provides for delivery of milk on the morning after being taken from the cow, or when the milk is about twenty-four hours old. The schedules from nearer-by points permit the shipment of milk taken during the afternoon hours, to secure its delivery on the market in New York next morning.

The following table showing the distances over which milk is carried by various lines into New York will indicate extension in point of distance of the milk-producing territory: these figures were prepared to take in the year 1895, since which time there has been some slight extension of distance on some of the roads; as, for instance, the Erie Railroad is now transporting milk from Cuba, New York, distant 383 miles from Jersey City; the Erie Railroad is now transporting milk a maximum distance of 389 miles; the New York, Ontario & Western a distance of 319 miles; and the Lehigh Valley Railroad a distance of 401 miles.

RAILROAD.	Year.	Town.	Miles.
Erie	1875-1884.	Port Jervis, N. Y.	87
	1884-1886.	Callicoon, N. Y.	135

New York Central Lines	1898.	Chatham, N. Y.	127 1/2

The growth of the milk business to the New York market is presented in the following figures, showing the total movement via all lines during the years named :

1886	5,449,612 cans of 40 quarts each.		
1887	5,814,864	—	—
1888	6,021,185	—	—
1889	6,276,084	—	—
1890	7,480,119	—	—
1891	6,932,788	—	—
1892	7,467,987	—	—
1893	7,552,913	—	—
1894	7,738,843	—	—
1895	8,027,040	—	—
1896	8,295,616	—	—
1897	8,628,043	—	—
1898	9,187,127	—	—
1899	9,489,136	—	—
1900	9,811,692	—	—
1901	10,218,169	—	—
1902	10,691,094	—	—
1903	11,425,387	—	—
1904	12,238,443	—	—
1905	13,059,728	—	—
1906	14,510,549	—	—
1907	15,061,079	—	—

The supply of milk and cream for the New York market, including adjoining cities) for the period 1886 to 1907 increased 176 per cent while the increase in the population during the same period was only 98 per cent. Using as a basis, the population in 1886, and the population in 1907, the annual delivered milk supply per capita of the population, increased from about 96 quarts in 1886 to 136 quarts in 1907, or an increase of about 40 quarts for each person. This increase in traffic has been made possible largely through special service afforded by the carrier, supplemented by protection against high temperature by refrigeration.

The passenger train movement outlined above, with an organization known as the Milk Department at point of delivery of the milk, has been contributed by the carrier; it has also contributed to opening up new territories of production, and has thus created a competition, augmenting supply, and stimulating consumption. The Management of a large carrier of milk advises that present methods meet the current requirements of the trade, and that improvements over the present methods of icing milk directly on shoulders of cans and bottles will be difficult to suggest, and expensive to adopt. In the same connection, a further statement is made that the opening of new territory more remote from point of consumption is not advantageous to the carrier and is adopted as a last resort and only when such action is

forced upon a carrier by the action of other milk carrying lines. In other words in the judgment of this same authority, most profitable results are to be obtained by intensifying the milk traffic from nearby points of production, on account of less expensive train service being sufficient and affording more satisfactory deliveries. It must be borne in mind, however, that the cost of producing milk at points nearer the market is necessarily greater than in the more remote sections, which lays upon milk produced on the valuable farming and grazing lands 50 miles of the place of consumption the burden of making a delivered price not greater than that offered by milk produced on the cheaper lands more remote from the market.

However, it would seem to your Reporter that so long as a service can be maintained from the remote territories, with reasonable degree of profit, there exists a duty as well as an opportunity to multiply and improve facilities to the utmost limit of the milk consuming capacity at the market, and thus aid in enhancing the value of additional territorial areas.

The carriers' duty is emphasized by a fact developed in the case of the Milk Producers Protective Association vs. Delaware, Lackawanna & Western Railway, decided by the Interstate Commerce Commission of the United States in 1897, stated as follows :

> A constantly growing demand in New York and adjacent cities cannot be met by Orange County, N. Y., or Sussex County, N. Y., and localities adjoining, if all the milk those districts are capable of producing is supplied. The development of far off milk region has been carried far beyond its natural demands, and a total supply made possible, which is much greater than the current requirements of the cities.

This governmental authority then does the carrier the justice of crediting to their efforts the above results in the following words :

> This has been accomplished through the free icing of milk in transportation by most of the carriers, through solicitations by railway agents and through facilities and other material aid to dealers and others, in the erection of creameries in more distant localities or the occupation of those already built.

Supervision of milk traffic among the more important milk carrying lines is delegated to a milk department, under the general direction of either the general passenger agent or general freight agent; the greater number of roads assigning this responsibility to the general passenger agent, with many of the roads the milk being handled in baggage cars on passenger trains and under a system of tickets covering the transportation charge. The local organization of the Milk Department at principal terminal markets, is described, in one case, as being made up of a milk freight agent, chief clerk, milk solicitor and stenographer, supplemented by a local delivering milk agent, with a force consisting of a cashier, platform foreman, clerks and necessary corps of milk checkers.

The Reporter has confined his observations to the Milk Market at New York, which is taken to be illustrative.

The milk products of butter and cheese shipped in boxes or cartons contemplates, particularly as to butter, the maintenance of a temperature between 30° and 35° : cheese, particularly the type known as American Cream Cheese, requiring mainly cleanliness and reasonably prompt service in delivery. It is true that during the recent past, particularly since the development of the foreign trade, butter is frozen and stored, it having been proven that frozen butter, particularly where it is necessary to store for considerable periods of time, is in much better condition than that which has been subjected to the ordinary cold storage arrangements. Frozen butter should be handled in the usual type of refrigerator car, iced with crushed ice, and 5 to 15 per cent of salt, reducing the temperature to hot exceeding 40°. Butter unfrozen, or in its normal state after manufacture, should be loaded in cars, iced with cake ice, in which a temperature of 45° to 50° is maintained. In colder climates, ice is not necessary during the winter months, although shipment under ice at all seasons is advocated by some shippers, who feel that the presence of ice tends to purify the air in the car.

Existing methods of cold storage for eggs has greatly increased their use, and transportation over long distances. Sound, unbroken, and otherwise perfect eggs, in cases, can be shipped successfully over short distances through the transportation agencies known as express companies, which conduct a package service on passenger trains, and are delivered to consumer in practically their natural state, but the obvious impossibility of supplying large consuming populations from producing territory immediately adjacent, has created two forms of preservation :

One, the transportation of unbroken eggs in their normal state, in cars iced with cake iced, at a temperature of 45° to 50°, to be frozen and stored in a temperature as near zero as may be convenient.

The other method; namely, breaking eggs into tin cans and freezing them, was first adopted by Mr. Henry J. Evans, vice-president of the New York Biscuit Company, who, at the time of his first experiment was using from 30,000 to 40,000 dozen eggs per annum. His plan involved the use of square tin cans, 9 5/9 by 13 inches inside measurement, each holding 5 gallons of eggs, or from 35 to 37 dozen. The can was fitted with a band of strap iron around the top to insure stiffness, also with a tight fitting tin cover, slipping down over the outside of the flange made by the strap iron. The eggs are broken into these cans immediately on their arrival at New York and Western points, and after the cans are filled their contents are frozen solid, and are held in a temperature to maintain this condition until used, when it is found that the eggs have retained their original sweetness and nutritious qualities. This form of egg shipment must be transported in refrigerator cars, iced with crushed ice and from 5 to 15 per cent. of salt, maintaining a temperature of from 35° to 40°, but a lower temperature is not undesirable. There is a small percentage of the movement which takes place is uniced cars, on the theory that the frozen contents will remain in that condition in an air tight car. To secure the exclusion of outside air straw is used around doors and other openings.

With the exception of milk, as described above, dressed poultry demands the greatest attention of all the forms of dairy products. This attention is first and most effectively given in the preparation of the fowl, and in essence, consists of the complete, but gradual removal of animal heat. For this purpose, two methods are in vogue.

One, for shipments known as iced poultry, involves the immersion of the freshly killed fowls in a vat of cool water immediately after killing, this water being changed two or three times during the first few hours up to at least twelve hours, when the poultry is placed in a vat of crushed ice where it remains for twelve hours longer. At the end of this twenty-four hours, the animal heat is entirely removed and the poultry is packed in barrels between layers of crushed ice, in proportions of about two of poultry to one of ice, a large cake of ice being placed on the top; the entire package being covered with burlap. An ordinary sugar-barrel will carry in this way from 175 to 200 pounds of poultry with about an equal quantity of crushed ice. This quantity of ice will depend on local conditions and the distances from market.

The other method of preparing poultry is known as the dry-packed, adopted by the larger and more important shippers in the United States, under which method the animal heat is removed by placing the poultry on racks in a cooling room, where the temperature is held from 32° to 35°; the period during which poultry is allowed to remain in the room varying from twenty-four to forty-eight hours. The poultry is then wrapped in parchment paper, either individually, or by lining boxes and placing papers between layers of fowls. The method of dry-packing has absolutely accomplished the most satisfactory results. As an example of the effectiveness of this method, an instance is cited of a large poultry shipper in one of the Western States who dry-packed and sent poultry to be frozen and stored in an eastern cold storage house, a distance of about 1,300 miles. The poultry was kept in storage for a period of from six to nine months, was sold and re-sold and finally shipped by Express Company in small lots to retail merchants. One box of this poultry was marked with the shipper's name and address, and through error the Express Company returned it in a warm car to the original shipping point. On its arrival, it was examined, and the poultry found to be in fine condition, notwithstanding an exposure of several days after removal from cold storage.

In other instances, poultry is frozen outright after the removal of animal heat. It is frozen solid and will keep an indefinite length of time, in a cool temperature.

Iced poultry is shipped in cars, iced with block ice, without salt, maintaining a temperating of 35° to 45°. Dry-packed and frozen poultry must be shipped in refrigerator cars, iced with crushed ice and 5 to 15 per cent. of salt in which a temperature of 35° to 40° must be maintained.

Pre-cooling of cars for transportation of poultry is an absolute necessity, the desideratum being to reduce the temperature of the car as nearly as possible to the temperature of the poultry. This pre-cooling is accomplished by icing with crushed ice, with from 5 to 15 per cent. of salt several hours before loading.

In loading dairy products, the purpose is to secure safe carriage and allow circulation of cold air in the car. The other essential being that where solid cars of iced, dressed poultry are shipped, the barrels should not be loaded one on top of the other, as the extra weight crushes the poultry in the lower barrels. Mixed shipments of dairy products and poultry should be loaded with the poultry in the end next to the ice bunkers, eggs to be loaded in cases length-wise of the car, boxes and tubs of butter, and boxes of cheese all on top of each other, all properly braced after loading.

Cars of dairy products are concentrated at large forwarding points and handled in solid trains as far as possible to some point where trains are broken up and individual cars forwarded to final destination. Expedited transportation is a necessity, but intelligent and effective refrigeration is of the first importance and will counteract the effect of delays which may occur en route. These methods have been briefly described above. Re-icing is necessary at intervals of twenty-four hours for the maintenance of required temperatures.

An important feature of the dairy products traffic is the operation of so-called " pick-up cars ", pre-cooled by icing to the required temperature, operated from some central point through a producing territory, stopping at designated stations to gather shipments of eggs, butter and poultry. The operation of these cars, while necessary, cannot, of course, prevent disadvantages of varying conditions of the different articles of traffic as delivered at the stations : and the impracticability of maintaining uniform temperature, with constant entering of the car to install the load. These " pick-up cars " are carried through to terminals, where their contents are concentrated into carloads for movement in solid trains where practicable, and by special service. The disadvantage alluded to will be difficult to overcome. The most important step in this direction would seem to be the systematic education of shippers in the best methods of preparing and delivering their property for shipment without the necessity of installing expensive plants : as illustrated, shipments of dairy products, hauled from the country, should not be allowed to stand in warehouses or on station platforms an undue time, awaiting arrival of " pick-ups " as the shipper should become familiar with the schedules and time his deliveries at station so as to avoid what might prove to be injurious detention to his property. To this end, transportation lines and shipper can co-operate : the one by the operation of a regular schedule with reasonably certain arrival hour for trains : the other by adoption of precautions indicated by common sense. The effectiveness of present methods of American transportation of dairy products is shown by the following figures, giving the volume of this traffic passing Chicago, eastbound, during a period of thirteen years.

The methods described above for handling dressed poultry and eggs received additional approbation from the producers of this class of poultry at a town in one of the mountain sections of a Southern State. These methods have been adopted in this section for about seven years, during which time the traffic in dressed

poultry has gone from small shipments at the beginning to a total output of 1,500,000 pounds, during the year 1908, and a total product of 35,000 cases of eggs for the same period.

YEAR.	Butter.	Eggs.	Cheese.	Dressed poultry.
	Tons.	Tons.	Tons.	Tons.
1893	64,130	32,097	9,040	16,251
1894	72,907	44,353	11,904	27,333
1895	84,433	48,116	9,663	27,012
1896	102,849	57,805	8,442	29,818

CHAPTER V.

Fruits and vegetables.

a) *Highly perishable fruits and vegetables.*

The early varieties of vegetables, embracing lettuce, early cabbages, tomatoes, radishes, asparagus, green peas, early onions, egg-plant, string beans, and squash, requiring a comparatively short time between planting and preparation for market, and containing a large percentage of water, quickly deteriorate after gathering. This deterioration occurs more perceptibly and speedily in the form of blight or wilt, which discourages consumption to probably a greater extent in connection with vegetables than with any other from of perishable horticultural products. Deterioration from decay sets up less actively, and is more easily combatable. Care in gathering and packing is of the highest importance in effecting a successful delivery to market. The produce is usually grown by numerous individuals at various way stations, requiring " pick-up " service between terminals where cars are

assembled in trains for long distance movements. In some exceptional instances, market gardens or farms exist of sufficient size to warrant solid car loading : similarly there are frequently a number of stations scattered through vegetable territory where produce is assembled by wagon haul, and loaded in car lots through to final destination. But that form of the traffic which the rail carrier is forced to assemble in small lots, calls for especially thoughtful attention to detail. Your Reporter finds that the service in a territory producing a large volume of vegetable traffic may be described as follows :

During the fruit and vegetable shipping season, we operate over the different divisions as the season is on, what we term " Fruit Pick- Up Trains ". This train on each division leaves the first shipping station on the district somewhere about four o'clock in the afternoon, so that the work of loading the less carload shipments is performed late in the evening, and at many stations after the sun has gone down, and the amount of heat permitted to enter the car while open, is reduced to a minimum. This train picks up the car load, and less than car load lots along the district at all stations, and upon arrival of the cars at the end of the district, they are placed in the through fast freight trains. Each pick-up train carries out of its terminal, empty ventilated cars, and empty iced cars to pick up the less car load shipments. The train carries, in addition to its regular train crew, a man who has charge of the loading of these less car load shipments, and he in turn will have three or four laborers under him to perform the work. The shipments are stowed, and properly stripped as fast as offered for forwarding, at the various stations, and when the train reaches its final terminal, the loading is finally shaped, and securely braced for transportation to destination, or break bulk point. The doors of the iced cars are permitted to remain open only for a time sufficient to load and strip the offerings at each stations and doors are kept tightly closed and fastened between stations. There is less complaint and trouble as to alleged improper refrigeration on these L. C. L. shipments, than on carload lots. The loaders are for the most part men who have been in this line of work in past seasons, and understand what is wanted. It is a rule to separate loadings, that is, one end of the car is reserved for highly perishable commodities, such as strawberries, and the other end is used for miscellaneous commodities, such as cabbage, beets, potatoes, etc., etc. It has been demonstrated that better results are obtained by not mixing the loading, and that the strawberry to properly carry to destination should be loaded in an end of the car by itself.

A variation from the pick-up service performed by rail carriers, as just described, appears in certain coast cities adjoining market garden districts, ramified by salt water inlets and rivers, on which small steamers and other water craft ply between the plantations and wharves at the shipping ports, for the assembling and transshipping of property. Certain wharves are usually assigned especially to vegetables. Despite the crudity of this assembling service and its dependence on tidal conditions in winding water-ways, a large and increasing volume of traffic is being developed. The co-operation of the rail carrier begins by furnishing the wharfage and necessary tracks for transfer from vessel to cars combined with a carefully planned schedule for quick delivery of property to market. Experience in the case

just cited, has shown that refrigeration is unnecessary, although this additional facility could be easily supplied. Thorough ventilation plays the most important part in the successful transportation of vegetables.

To secure immunity from blight and wilting of vegetables, no method so far adopted has proved so successful as shipment in refrigerator cars under ice. There are two commodities, namely, lettuce and green corn, which it is necessary, at certain seasons, to pack in hampers or barrels with crushed ice, giving the produce a fresh appearance at destination. Better conditions of produce at market are to be obtained, according to expert opinion, from the adoption of pre-cooling methods, a discussion of which follows later on.

Early fruits, or more definitely stated, highly perishable fruits, embracing berries, cantaloupes, musk melons, peaches, cherries, plums, and pears, are handled largely under refrigeration in cars cooled before loading, by fully charging ice tanks, — before loading if possible; if not, immediately after loading — with ice broken into irregular pieces, ranging from 25 to 50 pounds each, with enough smaller pieces to fill the vacant spaces. This will require, in a standard refrigerator car, from 8,000 to 9,500 pounds of ice. In the absence of accepted measures for pre-cooling, reliance is placed entirely on icing in advance of loading or immediately after the load is placed in the car. For the maintenance of proper temperature, re-icing must occur at intervals of twenty-four to thirty-six hours; the amount of ice consumed varying with the rapidity with which the load is cooled, and with the outside temperatures. A normally safe temperature is from 45° to 50° Fahr., which, if maintained, will secure satisfactory delivery over maximum distances now traversed by rail carriage, and permit the holding of fruits in efficient cold storage for further extended periods. These three cardinal principles in the fruit traffic, are the guide posts for individual managements to measures and methods necessary to meet individual situations.

b) *Ordinary perishable fruits and vegetables.*

Apples and cabbage, coming under the classification of ordinary perishable, must have protection against heat and cold, according to practice established by experience. The harvesting period for the larger volume of these products is identical, *i. e.*, in the late summer and early fall. From the far Southern sections, cabbage is harvested and marketed during the summer months. There are also shipments of early cabbage from market gardens in the higher latitudes, but the more important movement is that which occurs, beginning in late August and extending through the fall, winter and early spring months.

From the 20 of August to the 1 of November, refrigerator cars without ice are employed in the handling of both apples and cabbage. From 1 November to 1 December, stock and ordinary box cars, equipped with the "A" shaped form in the bottom of the car to provide ventilation, will meet the requirements for cabbage;

ordinary box cars satisfactorily transport apples. From 1 December to 1 March, refrigerator equipment is required for both items to protect against cold weather. From 1 March until the beginning of a new season in late August, refrigerator cars under ice are necessary for protection against heating.

Cabbage is shipped in bulk, with no other special arrangement than the contrivance in the bottom of the car for purpose of ventilation. This contrivance is unnecessary when the cabbage is shipped in refrigerator cars, and during cold weather.

In the early fall a few apples are shipped in bulk, and where the car contains different kinds of apples, ordinary wooden bins are provided to keep the different kinds separate. During most of the shipping season, however, apples are packed in barrels and tiered into car on sides of barrels.

Custom varies in the use or application of artificial heat in cold weather. In the extreme Northern sections, such as the State of Maine, Northern New York, and the Dominion of Canada, some method for securing artificial heat is a necessity. Further South, however, the large volume of traffic in apples and cabbage, has no other protection against extreme cold than lining the inside of refrigerator cars with heavy paper, and covering the floor with wood shavings.

Shipments of apples and cabbage in refrigerator cars over long distances and through varying temperatures, must have attention en route to secure ventilation when the outside temperature rises to such an extent as to injure the contents of the tightly-shut car, securing this protection by proper opening and closing of ventilators in a matter which has to be left to the individual judgment of employees in charge of the trains. It is fair to say, however, that these products are not so sensitive to cold, that result of neglect of this protection is always immediately noticeable. During extremely warm weather, when icing is necessary, the same watchfulness must be observed in providing this icing, as is the case with more sensitive products.

The white potato is perhaps utilized to a greater extent than any other vegetable : is cultivated with varying success in all sections, and does not require special protection against weather conditions, when shipped in the normal temperature of the temperate zone. It is noteworthy, however, that its production in greatest volume and with greatest profit, has taken place in extreme Northern latitudes, and has been made possible entirely by the building of railroads and furnishing of equipment designed to protect against extreme low temperatures. In the North-Eastern portion of the United States, lies a section which was a practically undeveloped timber tract, until the construction of a railroad about fifteen years ago, which traversed this section for 200 miles, including 60 miles of cultivated agricultural country. There had been prior to that time some cultivation of white potatoes, and the shipments had amounted to 40,000 bushels, greater production having been discouraged by lack of transportation facilities. Upon the completion of the railroad, and as a result of a campaign of education in the raising of white potatoes, the campaign being conducted by the railroad, collaborating with the Agricultural Department of the State University, a marvellous increase began in the succeeding

year in potato production, which is reflected by the following figures, giving the shipment of the railroad in question.

1894	1,500,000	bushels.
1895	1,600,000	—
1896	2,400,000	—
1897	1,300,000	—
1898	2,600,000	—
1899	2,900,000	—
1900	3,000,000	—
1901	4,500.000	—
1902	3,100,000	—
1903	5,300,000	—
1904	6,700,000	—
1905	7,700.000	—
1906	12,300,000	—
1907	6,000,000	—
1908	15,000,000 to 18,000,000 (estimated).	—

With the growth of the production has come an extension of area devoted to this crop. The railroad when completed traversed an agricultural belt 60 miles in length; at the present time, potatoes are shipped from 300 miles of the length of this road. A further effect of this development is a substantial increase in the value of farm lands, and greater prosperity for the owners.

The special facilities which have been demanded, consist entirely of artificial heating arrangements in freight cars. Temperatures during the winter are very low, averaging, according to expert observation, 15° to 20° below zero. The shipping season extends from the middle of August until the middle of the succeeding May, and with relation to the forms of protection employed for potatoes, is divided as follows:

From the middle of August until the middle of October, ordinary box cars are used, the side doors being left open about 3 inches and cleated in that position to furnish ventilation.

From 15 October to 1 December, shipments are made in box cars, lined inside with boards and paper.

After 1 December, until the beginning of moderate weather in the following spring, it is necessary to supplement the lining of cars by the installation of a stove within the car, at the expense of the shipper and supervised en route by an attendant who is employed by the shipper. Some shippers in preference to these stove-equipped cars, use cars fitted with patent heaters under a tariff of charges

payable to the owners of these patent cars, covered by the latter's guarantee of safe delivery of the property with certain reservations.

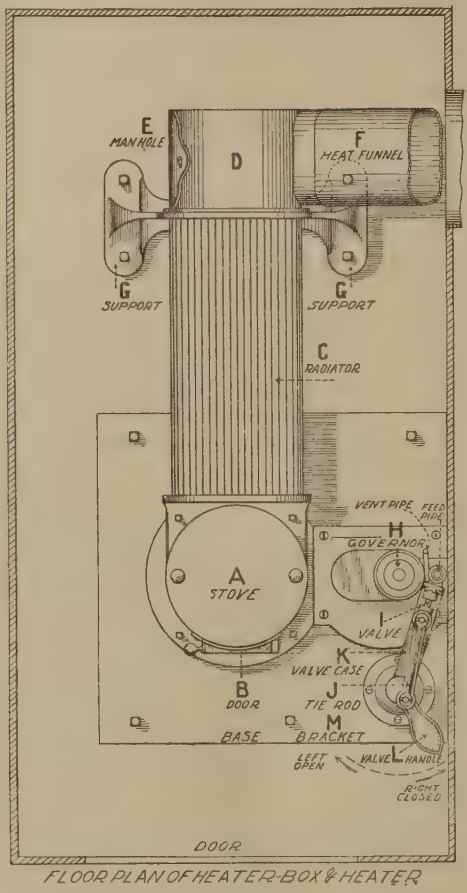

Fig. 8.

One of these patent heater cars is described briefly as an ordinary box car with hollow walls, constituting an air chamber surrounding the load: car equipped about the center of the car underneath the floor with a heater, the floor plan of which (fig. 8) shows a generator of heat in stove A, a radiator of heat C, and a distributor of heat through the ventilator F to the hollow wall of the car. The distinguishing feature of this device is its automatic action. It uses oil as a fuel, is wickless, and the supply of fuel and amount of heat are automatically regulated by

the outside temperature. The fires are lighted at point of origin and require no further attention throughout their movements to prescribed destinations, the most remote being 800 to 900 miles from point of origin. The tank carries 50 gallons of kerosene oil, fire-test 150 or better : oil furnished by the owner of the car. Cars contain no inside obstructions, and for return movement, will be loaded with ordinary freight. Under prevailing custom, they are placarded with the name of the shipper to whom they must be returned. The transportation lines through system of rules and instructions secure the return of these cars as placarded. The latest improved type of these cars has a capacity of 60,000 pounds with a length of 34 feet. Very detailed instructions are given to shippers by the owner of the car, designed to insure intelligent manipulation of the heating device. The following instructions apply to the heater illustrated above.

All parts of the heating apparatus which agents and shippers will have to handle, are designated by letters on floor plan of heater box and heater (fig. 8). For convenience a list of lettered parts is given below, with the letter representing each particular part on the left :

A . . . = Stove or heater.	H . . . . . = Governor.
B . . . = Door to heater.	I . . . . . = Valve.
C . . . = Radiator.	J . . . . . = Tie rod.
D . . . = Radiator end casting.	K . . . . . = Valve case.
E . . . = Manhole for cleaning.	L . . . . . = Valve handle.
F . . . = Heat Funnel.	M . . . . . = Bracket.
G . . . = Supports.	

To light the fire, swing the valve handle, L, to the left as far as it will go, then open heater door, B, and watch for the oil to flow into the base of the circular burner. As soon as the oil can be seen in burner, swing valve handle, L, to the right as far as it will go. Light the oil with match or torch, and wait for the flame to burn all around the circular burner, then for the second time swing valve handle, L, to the left as far as it will go. At this stage of the operation, see that the heater door, B, is fully closed, then close the heater box door.

The fire will regulate itself after being lighted. Do not try under any circumstances, to regulate the fire by placing the valve handle, L, in any particular position, because regulation of the fire by such means is simply impossible. Governor, H, will take care of the fire.

If the oil does not flow to the burner within a reasonable time after valve handle, L, has been moved to the left, as far as it will go, the reason it does not will be due to one of the three causes, namely : because there is no oil in the tank, the feed piston has become clogged, or on account of the oil having become congealed in the governor and pipe connections. In case of congealed oil apply a lighted torch and warm the governor and pipe connections, very slightly, as only little heat is required. Too much heat would be likely to cause leaks and make trouble.

To extinguish the fire swing valve handle, L, to the right as far as it will go. If the draft is too strong when fires are being lighted, partly open the heater door, B, to decrease the draft. If the heating apparatus is found out of order, shippers must not attempt to remedy the difficulty. Report the car as being out of repair to this Company's nearest Agent. It

is *not* expected the difficulties above referred to will occur only in rare and extreme cases.

Shippers must not tinker with heaters that are not in working condition. Report such cars to this Company's nearest Agent.

Cars thus equipped are not permitted to move beyond certain territories of destination: for example, cars in use by the Maine potato trade, are not permitted to move into the Southern States, and rarely move to destinations South of New York City.

These potatoes from Maine are distributed over areas as remote as the State of Texas: they are shipped in large quantities to the Southern States on the Atlantic seaboard: to interior points the movement is all rail, and to handling markets such as Boston and New York, where especially equipped cars are released and returned. Potatoes for long distance movements are usually shipped in sacks, facilitating transfers and protecting the product. Cars equipped with stoves, as first alluded to, are returned to the shipper, who installed the special equipment, in the same manner as the cars containing patent heaters are returned. The regulations adopted by an interested Railroad, governing the location of stoves in cars, as well as placarding for return of same follows:

There must be a sheet of galvanized iron at least forty-two (42) inches by thirty-two (32) inches securely nailed to the car floor. The stove must be securely fastened to the car in the center of this sheet of galvanized iron. There must be on this sheet of galvanized iron at least one (1) inch of ashes or earth under the stove. There must also be at least four (4) inches of ashes or earth in the bottom of the stove.

All wood work within less than thirty (30) inches of the stove must be protected by sheets of galvanized iron.

The stove pipe must pass through a metallic collar in the car door, or in a fire board that allows of at least one (1) inch space between the funnel and the wood work. The stove pipe must be at least thirty inches below the roof of the car, and securely fastened.

Outside the car, the stove pipe must be turned and must project up at least six inches and not over twelve (12) inches above the eaves, and must be exactly one (1) inch distant from the eaves. Stove pipe not to be over six (6) inches in diameter.

No holes shall be cut in car doors, where holes have not already been cut and proper protection furnished by the Railroad Company, owning the car.

The rules and regulations with regard to return boards are modified as follows:

While a return board of a size not exceeding eighteen (18) inches by thirty (30) inches is permitted, one (12) inches by twenty-four (24) inches is a much better size, and is recommended. All notices for return of cars must be on boards painted white, with the name of the party to whom the car is to be returned stenciled or painted in black on the white board, and should read similar to the following:

RETURN TO
JOHN DOE, HOULTON, MAINE.
Via. . . . . R. R.

Nothing whatever in addition to this can be permitted

Hereafter these return boards must be placed one on each side at the lower edge of the car over the bolster, on that end on which the number is painted, care being taken to see that it is not placed over the dimensions or tare of the car.

Return notices printed on paper or cloth and tacked onto the sides of the car with pieces of laths or boards around the edges, will not be permitted.

Station Agents and Car-Inspectors must see that these rules are strictly complied with.

As pointed out above, an attendant is necessary for these cars, who is employed by the shipper. This individual having in charge a maximum of five cars is given free transportation to destination of the cars, and is then returned at a special passenger rate to point of shipment.

Rentals are paid for the patented cars to their owners, varying from $12·50 per month to sums ranging from 15 to $25 per car per trip. These rental charges cover the use of the car, the service of attention en route, and the guarantee, under certain restrictions, of safe delivery. Expert opinion pronounces the devices now in use as adequate to the present demands and capable of caring for future developments within limits which may reasonably be anticipated. These observations are reported for benefit of Managements who have to deal with extremely low temperatures in the winter season.

Improved ventilation, insulation and pre-cooling.

As bearing directly on the transportation of fruits and vegetables, your Reporter will deal below with suggested improvements and with actual experiments, having for their object greater efficiency and economy in refrigeration as well as better condition of load at destination. These improvements seem possible along three lines, namely, ventilation, insulation and pre-cooling.

The employment of outside atmosphere for the preservation of perishables in transit, is attended by such variable conditions as to preclude anything more than general practice. Ventilation, of necessity, cannot be solely relied upon where outside temperature is continuously so high as to accelerate deterioration, and experience already gained by shippers and carriers combined with a general knowledge of the temperature changes to be anticipated throughout a given movement should usually protect against that danger. Dangerously low temperatures will be encountered, and in securing ventilation, great care must be exercised to properly graduate ventilation, as such lower outside temperatures are encountered. Access for outside air to interior of cars is gained in the case of ordinary ventilated cars by openings in the ends or sides, protected by gratings or screens; in the case of refrigerator cars, by opening hatches, removing plugs to ice tanks, and adjusting hatch covers to catch the air which is forced through the car and out through similar openings at the rear by the motion of the train. This latter arrangement has been so satisfactory that the construction of cars ventilated only at ends and sides is giving way to ventilated refrigerators.

Perishables moved under ventilation are either accompanied by attendants employed by the shipper, or are tendered to the carrier with specific instructions from the shipper as to ventilation to be used; or are tendered to the carrier, without instructions, for handling at his discretion.

The Railroad Refrigerator Service Association of the United States in circular No. 27, effective 1 July, 1908, establishes the following general principles to govern the three classes of shipments :

1° Shipments accompanied by messengers, are entirely within their control as to ventilation, and no instructions necessary on billing accompanying such shipments.

2° Shipments to be handled under shippers's instructions for ventilation, must be accompanied by definite and reasonable instructions, which must be shown on bill of lading, way bill, card-bill and transfer receipt; any of the following notations being acceptable :

" Standard ventilation,"
" Keep ventilators open to destination,"
" Keep ventilators open to. . . . . ." (See note.)
" Keep rear ventilators open to destination."
" Keep rear ventilators open to . . . . . ." (See note.)
" Keep ventilators closed and plugs in to destination."
" Close ventilators and put plugs in at . . . . . ." (See note.)
" Close front ventilators and put in front plugs at . . . . . ." (See note.)
" Open one (or two) side-door for ventilation at . . . . . ." (See note.)
" Side-door not to be opened for ventilation when temperature is below freezing (32°) ".

Note. — No points other than regular icing and inspection stations to be inserted.

3° Shipments entrusted wholly to the discretion of the carrier must not be moved except on waybills, card-bills or transfer receipts, which carry ventilation instructions. In the absence of authoritative instructions, perishables under ventilation will be governed by " Standard Ventilation Rule ", which reads :

Put in ice-plugs, close hatches and (other) ventilators when the temperature falls below freezing (32° Fahr.). Open hatches and ventilators and take out ice-plugs immediately the temperature rises above freezing.

Detailed rules, working out these general principles are enforced, although their successful application, and the satisfactory accomplishment of a movement under ventilation, seems to depend on the carrying out of the further following general rule:

Agents, conductors, inspectors and other employees in charge, must examine waybills covering perishable freight under ventilation, frequently determine temperatures, and examine all ventilating devices to see that they are set in accordance with instructions as governed by temperature. On account of temperature rapidly rising and falling during day and night, variations account of altitude, etc., conductors are especially cautioned to observe this rule and change the position of ventilating devices, whenever they are found to be at variance with waybill instructions. Make careful record of all changes made in position of ventilator and other devices, stating time and temperature, or other reasons for action.

These general rules of conduct are in successful operation on lines, members of Railroad Refrigerator Service Association, traversing territories reaching from California across the Rocky Mountains and arid Western plains to the humid sections of the Middle, Northern and Eastern States. They result from the intelligent observation of climatic and atmospheric changes by subordinates in actual charge of property, and in the opinion of your Reporter, can be made more successful only by education of these subordinates to still closer observation, of the existing natural condition of high and low temperature.

Ventilation which removes accumulated gases and heated air in the top of the car has not been entirely accomplished, and the suggested adoption of a device known as the Garland ventilator deserves the consideration of managements. This device is constructed on the exhaust or suction principle, which is designed to draw out the warm air and gases, permitting cool fresh air to flow in through the ordinary ventilators to reach the upper portion of the load, and in the cases of traffic under refrigeration, to permit the cold air to fill the space hitherto occupied by the warm air and gases. Moreover, in the case of shipments moving in ventilated refrigerators with the ventilators closed, because of too low an outside temperature, this Garland device sucks out the bad air and gases which form.

Figure 9 shows the base plan of the Garland ventilator.

Figure 10 shows the ventilator attached to the roof of an ordinary refrigerator car.

Figure 11 shows the side elevation, and

Figure 12 the end elevation of the device.

A study of Figure 9 shows the principle to be that of exhaustion or suction from the interior of the car through the opening from the car (XY) into the vent W, brought about by air forced by rapid motion of the train into the duct X'Y' past the mouth of the vent W connecting with the interior of the car. The arrangement of the ducts (X'Y') opening in opposite directions provides for movement of car in both directions. Tests of this device have shown that at a speed of 30 miles an hour, 10,000 cubic feet per hour is drawn from the car. Reckoning the cubic contents of the car as 2,000 cubic feet, one ventilator would exhaust the contents five times per hour, or once every twelve minutes; by increasing the number of ventilators to two, the exhaustion is twice as great. It is obvious that provision must be made for the inlet of an equivalent amount of fresh air, which is provided as above suggested, by leaving the ordinary ventilators open during seasonable weather, and in cases where the ventilator cannot be left open, and the exhaustion from the Garland ventilator cannot be omitted, regulation is had by a damper at the inner end of the opening next the car. In case of property handled under refrigeration, the Garland ventilator provides for the permeation of the cold air throughout the entire car up to the roof, and when cars are not in motion, an intake of warm air is prevented because of the denser interior atmosphere. On the other hand, in case of movements under ventilation with vents closed, because outside temperature is injuriously low, the damper or regulator at the inner end of the car vent can be closed,

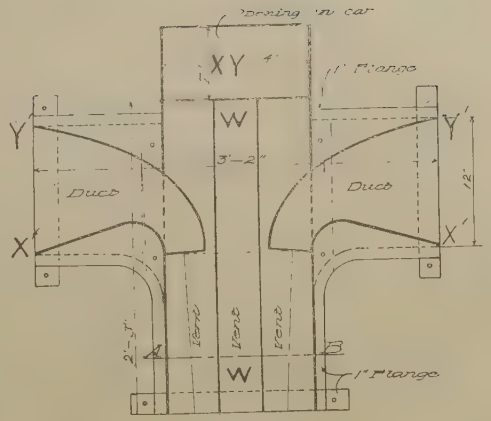

Fig. 9.

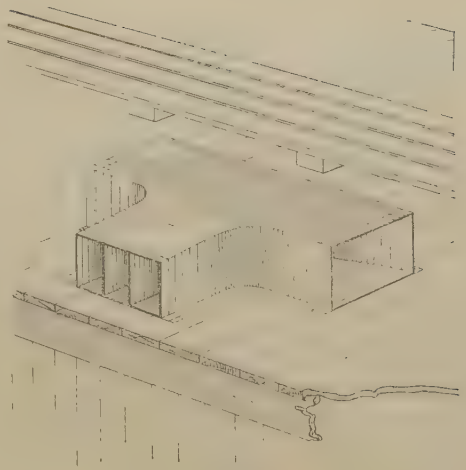

Fig. 10.

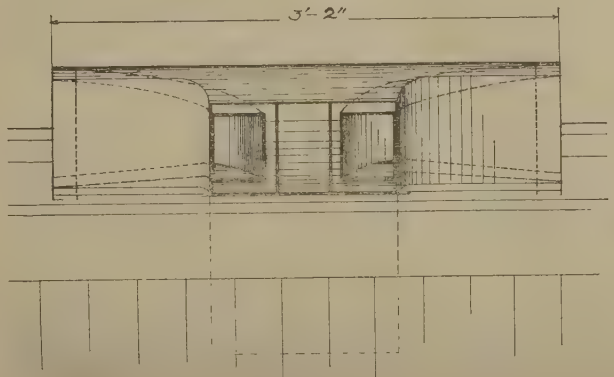

Fig. 11.

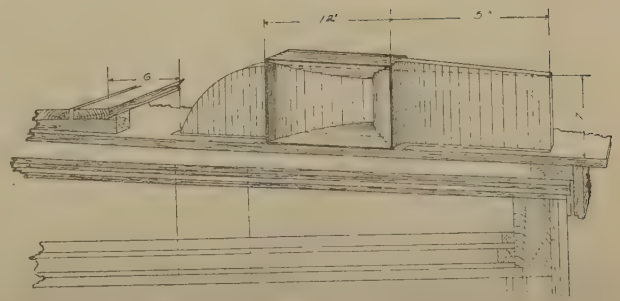

Fig. 12.

and prevent the admission of cold air. This device tends to procure equality of temperature throughout the car, which has been proved by actual test : as for example, a carload of strawberries shipped from Quincy, Ill., to St. Paul, Minn., in June, 1907, was found on opening to contain a temperature of 37° Fahr. at the ceiling, with the berries in the center of the car in as good condition as the berries at the end of the car next to the ice bunkers. The practical result of this test is appreciated, when it is borne in mind that the ordinary difference in temperature between floor and ceiling in a car under ice is from 15° to 25°. On a carload of peaches from Grand Junction, Colo., to New York City, equipped with a Garland ventilator, the difference between the floor and the roof was only 9°. The tests cited were conducted with cars and loads such as are ordinarily handled under refrigeration, and while the effectiveness of the device cannot be said to have been definitely proved, there is a clear suggestion of possibilities of improved condition of air in the upper part of the cars, permitting increased loading, with better revenue results, as well as a reduction in the number of cars required to conduct the traffic in perishable freight.

What is said above with regard to ventilation for gases and heat has been suggested by the handling of vegetables, but applies with equal pertinency to all classes of horticultural traffic, which is to be handled under ventilation or refrigeration.

Improved insulation, with its anticipated results of saving ice and better protection for fruit, is not accomplished without some loss of efficiency, either through increased dead weight or reduced cubic capacity. The latest experiment along this line has been conducted by the Pacific Fruit Express Company, collaborating with Mr. Bohn of St. Paul, Minn., its conduct and result being thus briefly described by Manager Secrist of the Pacific Fruit Express :

Two cars, one a standard refrigerator car, the other a standard refrigerator, fitted with six, instead of two layers of linofelt, were loaded with oranges at Harod, California, 6 October, 1908 : pre-cooled at Los Angeles, 7 October ; and moved east from Los Angeles, 5·35 a. m., 8 October.

The cubic capacity of the standard car was 2,059·45 cubic feet : of the improved car 1,851·18 cubic feet, or a loss in capacity of 208·27 cubic feet. This loss was shown, practically, by the ability of the standard car to accomodate 396 boxes standing on end, two tiers high leaving a free space to ceiling of car 59-½ inches with air space surrounding the entire load 4½ inches, while the improved car could only accommodate 372 boxes standing on end in tiers, the remaining 24 boxes being stowed on top of the load, lying flatwise, leaving only 18 inches from top of load to ceiling of car, and only 3½ inches air space surrounding the load. Each car was iced before leaving Los Angeles and re-iced seven times en route to Chicago. They reached Chicago with practically the same amount of ice in the bunkers, but with a saving of more than a ton and half of ice by the improved car, as shown by the following :

	Standard car.	Improved car.
Total ice used	22,035 lbs.	18,410 lbs.

Thermometers and a thermograph effectively placed but well separated in car and fruit, gave the following results as to temperatures of air, in the car and of the fruit.

Air temperatures in car.		Average of fruit temperature.	Where taken.	Date and hour.
Top.	Bottom.			
			Standard car.	
...	...	64·57	(Before pre-cooling) Los Angeles, Cal.	7 October, 2 p. m.
...	...	50·78	(After pre-cooling) Los Angeles, Cal.	7 — 6 —
55	47	49·4	Yuma, Arizona.	9 — 5.15 a. m.
52	42	48·7	Tucson, Arizona.	10 — 12.30 —
52	40	48	El Paso, Texas.	11 — 2 —
49	39	46·5	Del Rio, Texas.	12 — 6 —
49	39	43·3	New Orleans, La.	14 — 11 —
47	39	43	Mounds, Illinois.	16 — 6 —
47·5	38	42·14	Chicago, Illinois.	17 — 8 —
			Improved car.	
...	...	68·4	(Before pre-cooling) Los Angeles, Cal.	7 October, 7.45 p. m.
...	...	51·3	(After pre-cooling) Los Angeles, Cal.	7 — 11.45 —
50	42	50·7	Yuma, Arizona.	9 — 5.15 a. m.
49	42	50·7	Tucson, Arizona.	10 — 12.30 —
47	41·5	48·7	El Paso, Texas.	11 — 2 —
45	40	47·35	Del Rio, Texas.	12 — 6 —
41	40	45·3	New Orleans, La.	14 — 11 —
40	39·5	44·14	Mounds, Illinois.	16 — 6 —
39·5	39	43·6	Chicago, Illinois.	17 — 8 —

The following thermograph record shows both temperature, outside, as well as inside cars, with the responsiveness of the latter to the former :

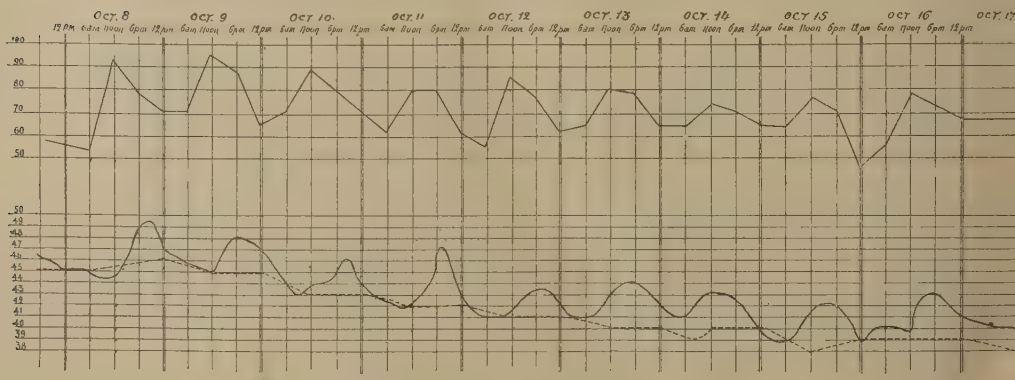

Fig. 13. — Thermograph records Los Angeles to Chicago 1908.

Note. — Heavy black line shows *standard car*; dotted line shows *improved car*.

Mr. Secrist's test confirms the apprehended loss of efficiency in carrying capacity. It further indicates :

« 1° An economy in ice ; 2° A greater depression of temperature in the inside air at the top of the improved car than occurred in the standard car ; 3° A slightly higher average temperature of fruit in the improved car throughout the journey ; 4° Almost an entire absence of response to outside temperatures, by the inside air of the improved car (show by figure 13) which seems to prove the efficiency of the increased insulation. »

While your Reporter has not ascertained whether any attempts are being made to adapt vacuum insulation to the preservation of perishables in considerable bulk in a single vessel, he suggests that if any such attempt has been made, the results might be investigated with success, following out the principle of the " Thermos " bottle, in which vacuum insulation is employed to preserve stationary temperatures in substances of small bulk.

Experiments on the other line, namely, pre-cooling, promise more beneficiary results to all varieties of the fruit and vegetable traffic, than any other measure now attracting the attention of producers and carriers. Tests carefully made by the United States Department of Agriculture, under the direct supervision of Mr. G. Harold Powell, Pomologist, in connection with citrus fruits from California, have shown that the ultimate result is the desideratum of every carrier's effort, namely, the extension of markets. After observing the results of his experiments and expressing his appreciation of the present refrigeration methods, permitting the delivery of perishable fruits and vegetables over thousands of miles, Mr. Powell thus summarizes his general conclusions :

The area over which horticultural products can be distributed in sound, wholesome condition has not passed beyond the early stages of practical development. There are two leading factors that lie at the foundation of a wider distribution of perishable products. The first is an improvement of the methods of handling in the fields and packing houses, in order that the keeping qualities of the product may not be impaired during the preparation for shipment ; the second includes an improvement in the methods of shipment under refrigeration to secure quicker refrigeration of the fruits and vegetables than is accomplished in refrigerator cars, in order to preserve and lengthen their life.

The first mentioned factor must come from the activities of the producer, but the following tables and diagrams are of collateral interest to carriers as an indication of the generous assistance they may well afford to extend Government authorities, and by the dissemination of pertinent literature for the enlightenment of producers. The experiments were made with duplicate lots of apparently sound brushed and un-brushed fruit, sound commercial fruit, and regular commercially packed fruit, and fruit showing visible mechanical injuries, such as stem punctures, clipper cuts,

*

and other types of abrasions. Shipments were made under ventilation and under ice. The following table shows the results under ventilation :

Table I.

TREATMENT OR CONDITION OF FRUIT.	Decay following immediate shipment and approximate delay of 2 days and 4 days.			
	(None.)	(2 days.)	(4 days.)	Average.
	Per cent.	Per cent.	Per cent.	Per cent.
Brushed fruit, apparently sound . .	1·4	2·2	2·7	2·1
Washed fruit, apparently sound . .	1·7	3·7	5·1	3·5
Commercially packed fruit	2·1	4·8	5·3	4·1
Mechanically injured fruit	9·4	15·0	21·7	15·4
Average . . .	3·6	6·4	8·7	

A graphic exhibit of the same results is found in figure 14.

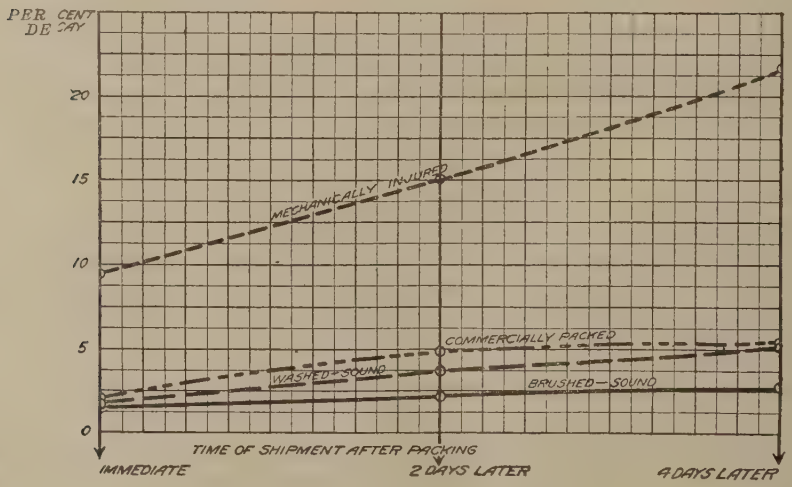

Fig. 14.

Results in connection with fruit carefully handled under commercial conditions on dates beginning in the winter season and lasting until warm weather has begun is shown in the following table :

Table II.

DATE OF FIRST SHIPMENT.	Decay following immediate shipment and approximate delay of 2 days and 4 days.			
	(None.)	(2 days.)	(4 days.)	Average.
	Per cent.	Per cent.	Per cent.	Per cent.
26 February	0·7	0·8	1·3	0·9
19 March	1·8	1·7	1·8	1·8
1 April	1·0	1·9	2·3	1·7
19 April	0·8	1·4	2·7	1·6
1 May	2·7	1·7	2·7	2·4
Average.	1·4	1·5	1·9	

The lessons to be learned by producers from these experiments are thus summarized :

1° Fruit that was handled the most simply, that is, apparently sound brushed fruit developed the least decay, while fruit from the same bins, but injured, in handling developed the greatest amount of decay;

2° Fruit shipped out promptly after packing developed much less decay than that which was delayed before shipment, the greatest injury being apparent in the fruit mechanically injured.

3° Ventilation is adequate protection for fruit during a large part of the shipping season, if the fruit is handled with sufficient care.

Other shipments were made under ice beginning in March and extending to the last of May, 1907, embracing on the one hand fruit which was handled in the groves and packing houses rather roughly, and on the other hand fruit from groves and packing houses in which was exercised more than the average care: both experiments covering sound brushed and washed fruit, commercially packed fruit, and

mechanically injured fruit. These results are displayed in table III, as to the rather roughly handled fruit :

Table III.

TREATMENT OR CONDITION OF FRUIT.	Decay following immediate shipment and approximate delay of 2 days and 4 days.			
	(None.)	(2 days.)	(4 days.)	Average.
	Per cent.	Per cent.	Per cent.	Per cent.
Brushed fruit, apparently sound . .	1·2	3·7	6·4	3·8
Washed fruit, apparently sound . .	2·0	4·2	8·1	4·8
Commercially packed fruit	3·9	8·9	12·6	8·5
Mechanically injured fruit	7·0	18·1	32·4	19·2
Average. . .	3·5	8·7	14·9	...

and table IV as to the carefully handled fruit :

Table IV.

TREATMENT OR CONDITION OF FRUIT.	Decay following immediate shipment and approximate delay of 2 days and 4 days.			
	(None.)	(2 days.)	(4 days.)	Average.
	Per cent.	Per cent.	Per cent.	Per cent.
Brushed fruit, apparently sound . .	1·0	1·8	2·6	1·8
Commercially packed fruit. . . .	1·0	2·6	4·6	2·7

Average. . .	3·3	4·5	7·3	

while figure 15 will present to the eye the same facts, as displayed in table III.

A study of these illustrations cannot fail to impress the intelligent and thrifty producer, and it is not difficult to discern the self-interest, which would induce the carrier to exert itself to see that these facts should be placed in the hands of its ally.

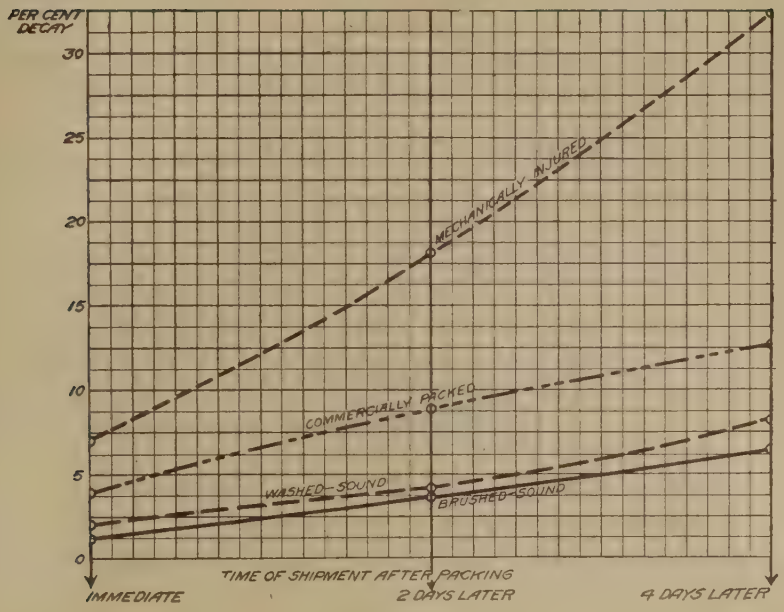

Fig. 15.

The additional suggestion of Mr. Powell belonging wholly in the realm of the carrier has been exploited and portrayed by experiments and illustrations equally instructive. The cooling of fruit before shipment retards the ripening process, checks development of decay and brings about equalization of temperature in the car. Ripening is accelerated by the separation from the tree, particularly in warm, moist climates : hence packing warm fruit in a car, notwithstanding it may have been previously iced and temperature effectively reduced, is followed by a period during which the refrigeration is to be communicated to contents, forcing the warm air to the top of the car, a process so gradual that the car may have covered half of its journey before the safe temperature of fruit is reached. This fact is illustrated by figure 16, showing results on two cars shipped in the same train under ice in May, 1907 : temperature of the fruit being the average of five different temperatures in each car taken as follows : two, half-way between the door and the end of the car; two, in the top tier in the middle of the car, and the fifth in the center of the boxes, in the lower half of the lower tier in front of the door. It is seen that it required practically four days to reduce the temperature of the fruit to the safety point, which temperature was maintained practically stationary to the end of the trip, notwithstanding there were fluctuations in some cases of 26° in the temperature of the outside air.

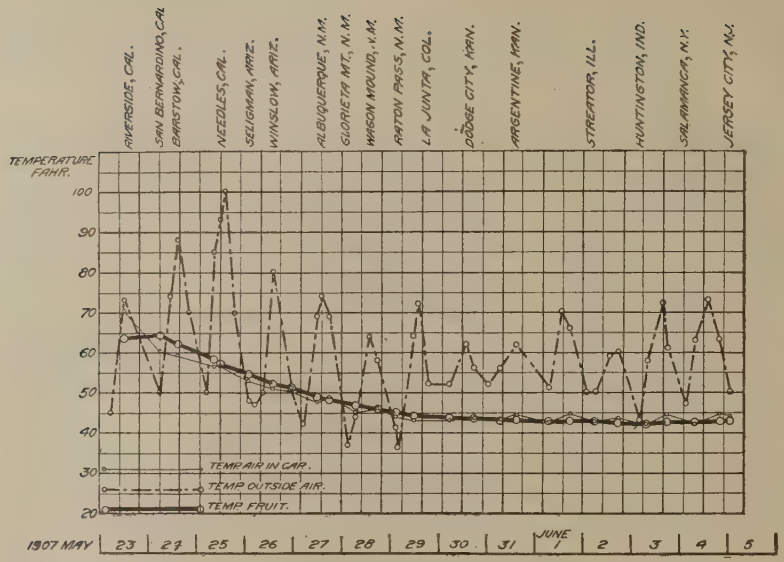

Fig. 16.

Cooling before shipment offers benefits to producers:

1° Ability to deliver fruit to the consumer in state of natural maturity, *i. e.*, the condition in which it would be gathered by consumer located at the point of production; 2° Reduction in percentage of decay and resultant pecuniary loss; 3° Better appearance of fruit and resultant encouragement to consumption; 4° Better keeping qualities after reaching destination, serving to provide if necessary longer time for distribution and preventing unremunerative prices through overstocked markets.

The first of these benefits to producers by pre-cooling is noticed particularly with reference to deciduous fruits, like the peach, plum, cherry, pear, etc., under which the most efficient standard icing methods require gathering before fully ripe, when transportation is to cover periods extending three or four days, reaching consumer insipid in flavor, toughened in texture and sometimes uninviting in appearance. Refrigeration promptly, after gathering, which retards ripening and holds the natural chemical changes in suspense, will remove this serious handicap to the efforts of the producer of these quick ripening fruits, who is widely separated from the consuming markets. Pre-cooling should therefore, be of great value to the deciduous fruit shippers.

The second of these benefits to producers by pre-cooling is very concisely pre-

sented in table V, covering shipment of pre-cooled oranges from California to New York in 1907.

Table V.

TREATMENT OR CONDITION OF FRUIT.	Decay following immediate cooling after packing and a delay of 2 days and 4 days.			
	(None.)	(2 days.)	(4 days.)	Average.
	Per cent.	Per cent.	Per cent.	Per cent.
Brushed fruit, apparently sound . .	0·1	2·3	3 4	1·9
Washed fruit, apparently sound . .	0 8	2 3	5 5	2·9
Commercially packed fruit	2·2	6 2	9 1	5·8
Mechanically injured fruit	3·0	9·2	13 9	8·7
Average . .	1·5	5·0	8 0	

These oranges were cooled to a temperature of about 40° Fahr. before shipment: and duplicate shipments were forwarded in which fruit was cooled as soon as packed: cooled in two days after packing; and cooled in four days after packing. The contrast between the percentages carried in this table and those carried in table III are too convincing to need further comment.

The third of these benefits to producers by pre-cooling closely follows the first two mentioned. Any of the deciduous fruits possessing desirable flavor and quality may be expected to retain their native appearance after allowing for the necessary action of wrappers and unavoidable bruises or indentations received in transit. On the other hand, citrus fruits which are precooled are seen to suffer less evaporation from the skin and present at destination, a round full appearance.

The fourth of these benefits to producers by pre-cooling is so far not fully developed. Mr. Powell's experiments were comparable only with respect to commercially packed fruit handled under ventilation only, and after pre-cooling. These experiments showed that there was a little less decay in the pre-cooled than in the ventilated car on arrival, and the development after arrival was slightly less. Proof was found, however, for the fact that pre-cooled fruit, which in reasonably sound is not more likely to decay after arrival in market, than equally sound ventilated fruit. It is a logical inference, however, that fruit whose ripening process has been so retarded as to secure delivery in approximately native ripe condition, will, if unexposed to varying temperatures, remain in this condition for a much longer period than fruit in which the ripening process may have set up, even for a short time, before being checked by the application of ordinary refrigeration methods. This claim is confidently made for pre-cooling by some of its advocates.

The experiments of Mr. Powell show that the carrier may anticipate advantages from pre-cooling on account of, (*a*) economy in refrigeration in transit, (*b*) increased loading for cars, (*c*) lessening necessity for extraordinarily high and expensive speed of trains carrying perishables without injury to contents.

Figure 17 is the record on a car load of fruit shipped from California under initial icing only, in May, 1906, with marginal table of distances traversed.

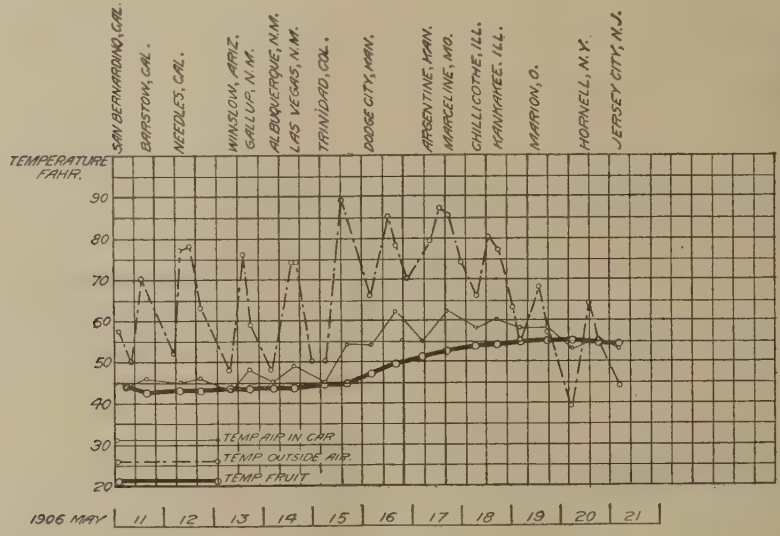

Fig. 17.

Distances in miles from.			*Distances in miles from.*		
San Bernardino,	Cal.	0	Dodge City,	Kan.	1388
Barstow,	Cal.	81	Argentine,	Kan.	1752
Needles,	Cal.	260	Marceline,	Mo.	1863
Winslow,	Ariz.	552	Chillicothe,	Ill.	2081
Gallup,	N. M.	680	Kankakee,	Ill.	2215
Albuquerque,	N. M.	838	Marion,	O.	2527
Las Vegas,	N. M.	970	Hornell,	N. Y.	2923
Trinidad,	Col.	1104	Jersey City,	N. J.	3255

The fruit was loaded at a temperature of 42° Fahr. — the car having been previously iced, It was re-iced before leaving California, receiving no further refrigeration, and reached Jersey City with about 700 lbs. of ice in the two bunkers. The outside temperatures, although warm during most of the trip, having the counterbalance of cooler night temperatures, did not cause marked increase in the temperature of the fruit until practically summer heat was encountered about half the distance to destination. Then the rise was gradual, with a further indication of

responsiveness to outside temperatures by a tendency to recession, when cooler weather was encountered near the end of the journey. Contrast this record with that shown in figure 18.

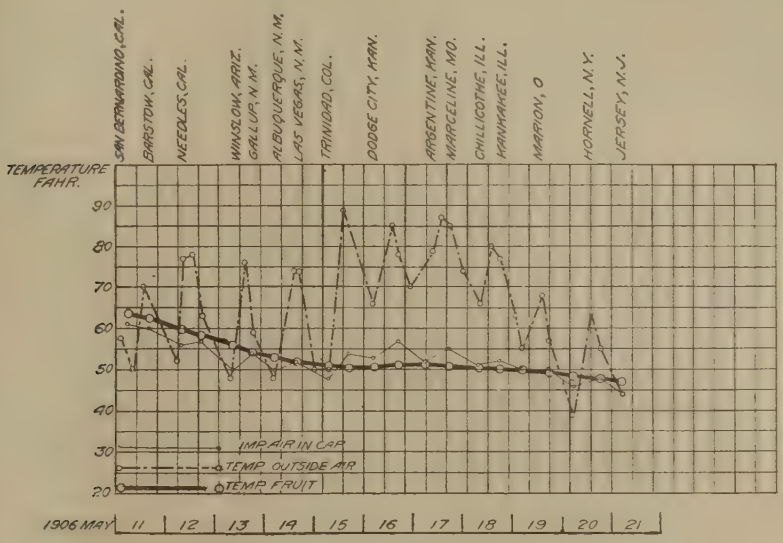

Fig. 18.

of a car handled in the same train, under regular icing, in which fruit, loaded at a temperature 63° Fahr. did not reach a safe and stationary point for four days after movement began, showed responsiveness, although in a less degree, to outside temperature, but did not go below 50° during the warm weather. Bearing in mind table V, previously inspected, which shows from record of percentages of decay, the great advantage of prompt refrigeration after gathering, it may be safely concluded that the condition of contents of the pre-cooled car was much better than of the regularly iced car. It may be further concluded that in the case of this shipment, the re-icing expense at all regular re-icing stations between California and Jersey City — probably seven in number — has been avoided without sacrifice to quality of fruit. This economy may be roughly estimated at from one to two tons of ice per car for each regular station.

It is only proper to report that expert authorities dissent from this conclusion. Mr. J. S. Leeds, Manager, Santa Fe Refrigerator Despatch Company, in a paper recently submitted to the International Congress of The Refrigeration Industries, says:

It has been demonstrated that a car of fruit which has been cooled down to 40° to 45° Fahr.,

and subjected to the same re-icings, as we term standard refrigeration, will take less ice in the re-icings for about five days. Then two cars, one pre-cooled and one not, travelling in the same train will equalize as to temperature inside the car. The natural shrinkage from decay will be less in the pre-cooled car, but the cost of service something more. The saving in ice will not pay for the added expense of pre-cooling.

The statement of Mr. Leeds that temperatures equalize in the two cars receives support by comparing the chart shown as figure 19

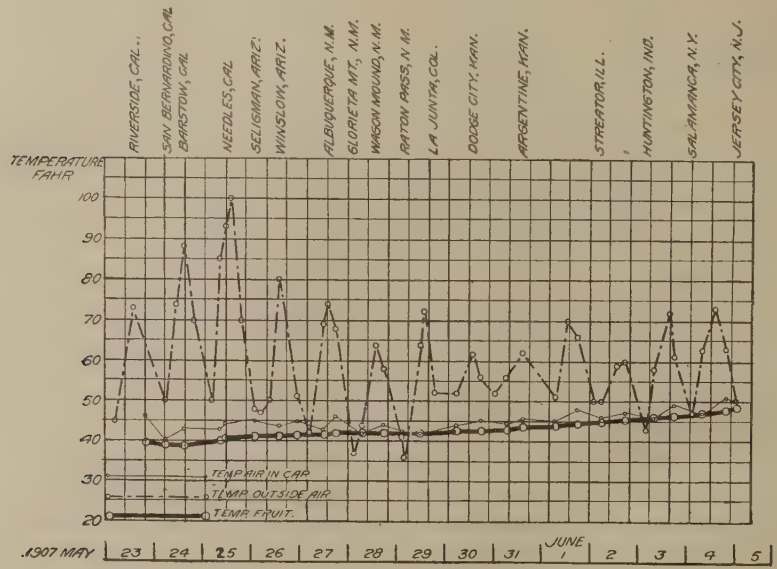

Fig. 19.

giving temperature record of a carload of fruit pre-cooled and shipped under initial icing, only in May and June, 1907, with chart shown as figure 16, giving record on car shipped in same train under regular icing. In these cases, outside temperature was high at the commencement of the trip, retarding action of the refrigerant in the cars under icing (fig. 16) and tending to accelerate rise in temperature of the pre-cooled shipment (fig. 19). It is noticeable, however, that while the drop in temperature in the cars under icing to the safety point required approximately five days, the temperature in the pre-cooled cars did not get above the safety point at any time during the trip, covering a period of twelve and one half days, and shows such gradual rise as to deliver fruit in condition as satisfactory as that of fruit transported in the car under icing where temperature, after reaching the safety point, remained stationary during remainder of the trip — a period of seven days.

Briefly, these charts apparently demonstrate that initial expense of precooling is off-set measurably by saving of refrigerant en route, without detriment to fruit.

The most potent benefit to carrier from cooling before shipment, lies in increased loading of equipment. The system of gravity circulation of cold air from ice bunkers is essentially ineffective in securing uniform temperatures for upper and lower tiers of load. The dense cold air seeking the bottom of the car will gradually cool fruit, and drive heat and gases to the top, where temperatures are, at the end of the trip, always higher than in the lower tiers. This fact is clearly presented by figure 20.

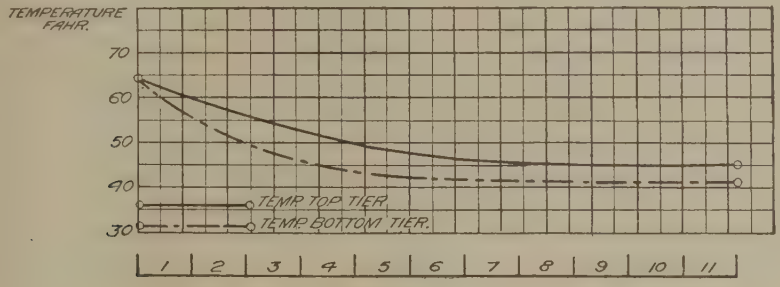

Fig. 20.

The cooling of fruit to a temperature of 40° to 42° Fahr. before shipment, saves refrigerating energy required to expel heat naturally stored in the fruit, and affords a uniformly safe temperature throughout the car from the moment of loading. This permits utilization immediately of a larger portion of the cubic space within the car. Tests have, so far, been applied to shipments of oranges from California, but their results may fairly be applied the other forms of perishable horticultural products.

The method of stowing California oranges for shipment under standard icing regulations, to secure minimum decay in upper tiers, and maximum loading, is shown in figure 21, with two tiers of packages, six packages in each row, standing on ends.

This method provides a load of 384 boxes, at an estimated weight of seventy two pounds each, total 27,648 lbs. The spaces for circulation of air throughout this load occur between the individual packages, with additional space between the outside packages and the walls of the car.

The experimental shipments of pre-cooled fruit were stowed as show in figure 22, with three tiers of packages, seven packages to each of the bottom rows standing on end, and seven packages to the top row laid on the side.

This method provides a load of 549 boxes for the standard 40 foot car, or an increase of 42·9 per cent. This shipment made under initial icing only showed

temperature changes in the three tiers, as indicated in figure 22, with a difference of approximately ten degrees between the top and bottom tiers, and about the same measure of difference between the temperatures in the top tier at the beginning and the end of the trip. While this test shows six degrees greater difference between bottom and top tiers than that presented by figure 21, covering fruit under standard icing, it must be remembered that initial icing only was applied to the pre-cooled fruit, and the conclusion is warranted that with even modified intermediate icing, the difference between temperatures in the top and bottom tiers would have been lessened, and an increased loading secured, more than compensating for the expense of such intermediate icing. If, however, it should be deemed desirable not to supply intermediate icing for the purpose of reducing difference in temperatures in top and bottom rows, in that case by leaving off the horizontal top tier and confining the load of two tiers, each seven rows wide, satisfactory results may still be secured. Such method will secure a load of 448 boxes per car, or an increase of 16·66 per cent. under initial icing only.

From these premises it will be seen that pre-cooling secures an increase in efficiency of equipment directly remunerative to carrier and indirectly advantageous to producer, without any increase in dead weight.

Pre-cooling retards the development of decay; it, therefore, lengthens the period within which the fruit may be safely held and presents to the carrier the added benefit of avoiding extraordinary and expensive speed for trains handling the traffic. Improvements in material and construction have for their object the production of cars which will stand higher speed; inasmuch, however, as these efforts tend on the one hand to a much greater cost of equipment, and on the other hand, to an increase in its dead weight, there is an evident limit to such efforts, and the carrier may well give careful attention to the desirability of this pre-cooling feature, which, by rendering traffic less perishable, continues the availability of existing equipment and lessens the risk attending high-speed operations.

A successful pre-cooling device must reduce temperatures with small delay to movement of fruit. Placing it in cold storage involves delay of several days, while subjecting it to a simple blast of cold air, entails delay of from twelve to twenty-four hours.

It would be very expensive, if not entirely impracticable, to provide cold storage arrangements adequate to treatment of the fruit crop, from any given section; on the other hand, the conditions under which the crop is placed on the market will prohibit the detention of even twenty-four hours at shipping point. Experts employed by the United States Government, as well as interested private individuals have, therefore, sought a material reduction in time required for pre-cooling, and results so far commend what is known as the Intermittent Vacuum principle. This principle utilizes the well understood action of air introduced into a vacuum or into a body of air, which has been rarefied by reduction of normal pressure.

Expansion of the introduced air takes place and permeates solids enclosed in the

Fig. 21.

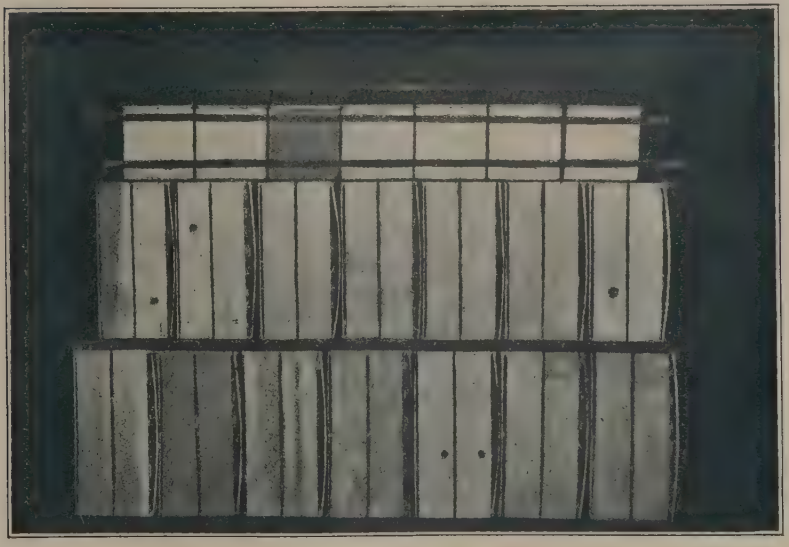

Fig. 22.

vacuum. Following this idea, a car loaded with fruit and tightly closed has, attached, pipes at each end through which the air is drawn by powerful suction: this suction is supplemented by the introduction, through a third pipe attached at top and center of the car, of a volume of cold air, powerfully driven, which, by a distributer, is dispersed in equal volume and pressure to all parts of the car.

A mechanical contrivance intermittently breaks the current of inrushing cold air, creating the needed vacuum, causing the expulsion through suction pipes of warmer air and gases and affecting the refrigeration of fruit to its center to a temperature of 35° to 40°. This is accomplished in a space of three or four hours, while an absolute equalization of temperature within the entire car takes place in twelve hours.

Your Reporter understands that this method has received careful investigation by the Pacific Fruit Express, C. M. Secrist, General Manager, Chicago, Ill., and by the Santa Fe Refrigerator Despatch Co., J. S. Leeds, Manager, Chicago, Ill., in connection with the movement of perishables from California.

CHAPTER VI.

Tropical fruits.

In the list of tropical fruits, the banana and the pineapple are representative and typical owing to their greater popularity and availability as compared with other tropical fruits.

The banana.

While there has probably been for a great many years more or less importation of bananas, as well as other tropical fruits, by civilized countries from nearby tropical regions, the earliest beginning of the present extensive and successful traffic in bananas to the United States may be placed in the year 1872, and accredited to Captain L. D. Baker, of Massachusetts, who sought a return load for his schooner which carried New England fish to the West Indies. The experiment was probably undertaken without serious expectations of profitable results, but the readiness with which he disposed of his cargo, led other fishing craft trading with the banana-producing countries to similar efforts, all more or less under the direction of Captain Baker. Ultimately the Boston Fruit Company was organized, which subsequently became the United Fruit Company. From this fortuitous experiment in transportation, the traffic has grown to the importation into the United States alone, during 1903 of 30 million bunches, or about 3 billion bananas, an average of about forty bananas per annum for each individual consumer in the United States.

The development of this traffic, aside from the thorough organization for produc-

tion and distribution has been ably contributed to by increasingly efficient transportation methods by water and rail.

Whereas, deciduous fruits are notoriously more palatable if gathered in a perfectly ripe state, the banana is improved by being gathered ten days or two weeks before its delivery to consumer in the markets of the United States. The fruit, although green, has attained full growth, and calls for a temperature and humidity which will not check the ripening process. The organization of equipment and forces for supplying the major portion of bananas consumed in the United States, is mainly under the direction of an institution whose ships are especially built and equipped for the satisfactory transportation of the banana. The fleet numbers upwards of seventy-five vessels, in addition to which there are railroads in Central America that reach the banana fields, thus providing for the handling under one system of supervision from field, through port of entry in conjunction with the rail carriers, to markets of consumption in the United States, even to points most distant from the ports of entry. The success of the industry is built mainly on improved methods of transportation, which have sought (*a*) delivery to consumer within the maximum-period of development to full maturity, and (*b*), a constant temperature which while preventing too rapid development and the shortening of time margin for delivery, does not injuriously check the ripening process.

Fourteen days, probably represents the average period within which bananas should be delivered from the grove to foreign consumer. This requirement is now met by short rail hauls to tropical ports, supplemented by fast steam vessel service to ports in the United States and rail schedules beyond these ports averaging from twenty to twenty-six miles per hour. Quick movement by vessel and rail carrier beyond port of entry has been accomplished entirely through complete co-operation from each of these factors in the service; the water carriers contributing vessels built for speed, a thoroughly organized inspection service, both at port of export and port of entry and intelligent supervision of condition of fruit from the moment of its delivery to vessel to its unloading from cars in the interior; on the other hand, the inland carriers have provided extensive and valuable wharf facilities laid with all necessary tracks, and unfailing supply of ventilated refrigerator cars, special attention to other terminal and rail services, especially operated schedules approximating average passenger train movement and special facilities at terminal points en route for re-icing fruit under refrigeration, or affording protection against extreme low temperatures in the outside atmosphere, — all designed to effect handling with a minimum expenditure of time.

Movement facilities may be said to be satisfactorily organized, and further improvements will be needed and anticipated mainly to care for unusual conditions and expanding volume of traffic.

Experience in the handling of the banana supports the conclusion reached as to less sensitive products, that future progress must be expected from measures to secure constant temperatures.

In discussing suitable temperatures for safe storage of perishables, Seibel says :

For bananas, no rule can be made ; the exigencies of the market must govern the ripening process which can be manipulated at will.

While it is possible to regulate the ripening process, experience shows clearly that the banana will blight if subjected to a temperature as low as 45° Fahr., and will reach premature ripeness if continuously subjected to temperature of 90° Fahr. — its sensitiveness to cold probably being the more noticeable. These cardinal points established, the regulation of temperature must begin with very careful inspection at shipside, which culls out the nearly ripe fruit, which is placed on the local or contiguous market for consumption. This loading inspection must be attended by close observation of temperature records inside and outside of car, and followed by inspection of attendant as far in the direction of final destination as economy permits. When high outside temperatures prevail at port, icing is required for long runs, the amount of ice used being determinable by this outside temperature. When outside temperatures at port are low, or approach the danger line, fruit stowed on arrival with more or less natural heat from its tropical origin, is loaded promptly into cars, and all ventilators closed to retain its natural warmth. Where temperatures at port are temperate, *i. e.*, 60° to 65° Fahr., thermal condition of fruit en route is regulated entirely by care of attendant through the use of ventilators, and depends on the expert judgment and skill of the individual attendant.

This description of present methods for securing safe temperature, leads to the query — How may the inevitable fluctuations in outside temperature be off-set and a safe constant provided? This safe constant is given by experts as 52° to 58° — or approximately temperate degree on the Fahrenheit scale, and when called upon to suggest improvements over regulation by ventilation and icing, an officer of a fruit handling company of long experience and expert knowledge, could only propose the installation of devices for mechanical refrigeration and steam heating en route — remarking at the same time that the expense necessary to effect these improvements would hardly be justified by any increase which might be reasonably expected from the adoption of such devices. It is, therefore, beneficial to study measures for increasing the efficiency of the individual attendant and inspector.

To accomplish the result, there is no better method, next to the exercise of care in the original selection, than a system of reports which are subject to verification as to accuracy. Reports devised and adopted by a successfull " banana carrier ", operating steamship and rail lines, as well as marketing fruit :

First. — Of the wharf department (form A, hereafter);
Second. — Of the messenger in charge en route (form B, hereafter).

Call for a minutiæ of information of condition of car, contents and appliances which requirement is likely to secure efficiency from the individual who has to make out this report. The percentage of moisture or humidity in the atmosphere

influences the process of development in bananas, and requires intelligent observation and regulation by the attendant. The reports just alluded to do not call for a record of these observations, and, it would seem, might be improved in that respect.

The pineapple.

Traffic in pineapples to interior markets in the United States, in a peculiarly emphatic way, reflects the assistance of an efficient transportation.

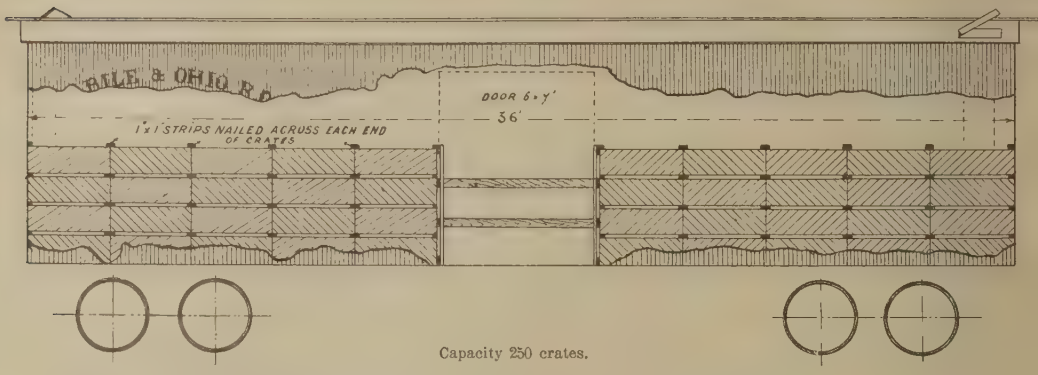
Pineapples have been imported by steamship to New York since the establishment of steamship service between that port and the West Indies. Prior to 1901, the fruit was handled in barrels, a type of package which developed a large percentage of decay, owing to the large volume of fruit in the individual package, and consequent weight and crushing of the individual pines. During this period no strong effort was made to trans-ship pineapples to interior markets except through the Express Companies, the consumption being chiefly confined to New York territory. There were some less than car load shipments by the Express Companies of fruit which had been culled from the barrel shipments by steamer. This resulted in a duplication of handling through the distributors both at New York and interior markets, which brought about a price for the individual pineapple in the markets situated in the central part of the United States, so high as to constitute the pineapple an article of luxury. In 1901, the type of package was changed from barrels to crates, producing smaller units and avoiding a large percentage of loss from decay. About the same time, steamship service was inaugurated from West Indian ports to Gulf ports in the United States, which was supplemented by fast freight train schedules from the ports to interior distributing points.

This combination of fast steamship and rail service in addition to making delivery to the Interior Western Markets in possibly two-thirds of the time consumed for movement through New York, eliminated the offices of the intermediate handlers at New York, and the larger Western Markets, and enabled the producer to place his fruit directly into the hands of the distributor at secondary interior markets. This immediately accomplished two results : firstly, — a lowering of prices and encouragement of consumption, and secondly, — increased profit to the producer and augmented production. Pineapples under the former method of transportation and handling, cost the distributor at Chicago approximately twelve dollars per barrel. The same fruit now costs him approximately one half of that figure. The sequel to this condition is that the individual consumer who formerly paid as much as one dollar for his pineapple, can now purchase the same fruit at not exceeding 40 to 50 cents.

Pineapples do not require icing, the movement taking place entirely under ventilation. The trans-shipment at the port is conducted with the same efficiency and rapidity as characterizes the handling of the banana. Although refrigeration is unnecessary, the fruit is loaded in ventilated refrigerator cars to get the benefit of

*

the insulation. The loading is done by employees of the rail-carrier, and the accompanying illustration (fig. 23) gives the details of this loading as practiced at Gulf Ports which is designed principally to secure thorough ventilation.



Capacity 250 crates.

Size of crates.

Fig. 23.

Dotted lines show ice box in each end of car. Allowance in loading must be made for same.

The fruit is gathered full grown, but unripe, and is ripened in transit. It is stated by expert dealers that this is a necessity and that the introduction of refrigeration or faster schedules will not necessarily overcome this requirement and

secure delivery of fruit to consumer in its state of natural ripeness. Whether quickened transportation and the improved methods of ventilation and refrigeration, as applied to the perishables, enabling the gathering of the fruit from the stalk in ripe condition and delivery to consumer before material deterioration sets in, will encourage consumption, has not been determined by conclusive experiments. Although, the opinion of one familiar with the trade inclines to the view, that even were it possible to permit pineapples to fully ripen on the stalk, the improvement in texture and taste would not necessarily increase consumption. In answer to a direct question, an expert made the statement that he had no suggestions to make looking to improved rail service; that there was always room for reducing the percentage of decay by more intelligent culture and methods of harvesting, but, in the main, the existing transportation facilities will insure a continuance of the growth of this traffic.

The total importation of pineapples into the United States for a period of nine years, 1900 to 1908, inclusive, given below, allowing for fluctuations in the crops due to varying weather conditions, is strong testimony to the efficiency of existing methods :

Year 1900	341,657 crates.	1,366 cars.
— 1901	344,754 —	1,378 —
— 1902	496,353 —	1,945 —
— 1903	787,369 —	3,149 —
— 1904	646,470 —	2,571 —
— 1905	828,417 —	3,313 —
— 1906	878,962 —	3,515 —
— 1907	637,795 —	2,551 —
— 1908	960,000 —	3,840 —
	5,921,727 crates.	23,678 cars.

As indicating the effect commercially on individual sections, the history of pineapple growing in Florida tells of the beginning of the movement in 1883, when the entire shipment amounted to 5,000 crates; in 1908 it had grown to 690,000 crates, under the same general methods of handling as described above.

CHAPTER VII.

Fish.

The flesh of all kinds of fish is peculiarly sensitive to thermal changes, and is well known to be a form of perishables requiring thorough protection. For this reason, its use in a fresh or uncured state was almost entirely seasonal prior to the utiliza-

tion of the processes of refrigeration, both in cold storage and in transit. At the present time, the markets of every important center and many of the smaller ones carry, daily, a supply of fresh fish of numerous varieties; the blue fish, halibut, uncured cod, lobsters and oysters of the Atlantic Coast, and the pompano, Spanish mackerel, red snapper and oysters of the Gulf of Mexico being as frequently found on the tables of Western hotels and residences, as the salmon, white fish, lake trout, pike and bass constitute an accepted and expected item in the bill-of-fare for residents of the Eastern and Southern States.

This is directly attribuable to methods, which freeze the fish intended for distant destinations immediately upon its removal from the water, move it under refrigeration to destination and hold it — in some cases — for many months in specially constructed cold storage.

The present general distribution of fresh fish in the United States dates from 1830, and has progressed from the plan of cooling in the holds of fishing smacks by ice which was not allowed to come in contact with the fish, through arrangements for stowing in crushed ice and delivery at near-by points, to the present complete processes whereby fish especially sensitive to atmospheric exposure are transferred directly from native waters to freezing rooms in the holds of vessels, frozen stiff before life is yet extinct from other causes and are subsequently delivered to distant markets, retaining all their original flavor.

Attention may here be properly drawn to the fact that, although fresh meats are injured by coming directly in contact with ice, and the refrigerant has to be applied indirectly to shipments of fresh meats; in the case of fresh fish, the best results are obtained by applying the ice directly to the fish.

Supplies intended for near-by markets may require only packing with a proper amount of crushed ice in boxes or barrels, and for such shipments, usually handled by Express Companies on passenger trains, the controlling considerations are distance, season (or temperature) and quantity of ice, which are too variable to admit of arbitrary rules. Although, one large house has suggested the following formula, based upon an approximate temperature of 70° Fahr., throughout the journey.

AMOUNT OF FISH.	12 hours en route.	48 hours en route.
15 lbs.	10 lbs. of ice.	20 lbs. of ice.
25 —	20 — —	25 — —
50 —	25 — —	30 — —

An Oregon firm shipping fresh salmon to New York in boxes 20 by 44 by 12 inches in size, applies 75 lbs. of ice to 175 lbs. of fresh fish from the water; boxes to be

re-filled daily at icing stations en route, at the expense of the Express Company, whose charges include the cost of this re-icing. Under this latter method each car is loaded with twelve tons of fish.

Probably the most successful of existing methods is seen in the shipment of frozen salmon from the fisheries of the Columbia River to New York, handled by the carriers in refrigerator cars. For this movement, the fish are usually frozen solid as soon as caught and piled up like cord-wood until ready for packing. After being dipped in cold water to secure a coating of thin ice and preserve quality and appearance, the fish are wrapped in oil paper with an outer coating of thicker paper and packer in boxes, which are stowed in the refrigerator car, allowing a few inches space between boxes and car walls for saw-dust insulation. The car bunkers are then iced with a mixture of 10 per cent. salt and 90 per cent. ice, which is maintained to destination.

Statistics showing the development of this movement are not available, but the achievement of a successful delivery of fresh fish by refrigerator car over a distance of more than three thousand miles, unquestionably demonstrates its efficiency.

It is equally suggestive of the success of present methods for handling that shell fish are found — in practically every important center on the American Continent, regardless of climatic surroundings; the lobster originating entirely in New England and Nova Scotia, being as well established in the restaurants of New Orleans or St. Louis, as in New York. In like manner, the oysters of the Eastern Coast are to be found alive in the shell in the markets of the Southwest and West.

The annual catch of lobsters on the coast of New England and Nova Scotia is estimated at 6 million pounds, — two-thirds of which is trans-shipped at Boston from fishing craft into facilities for holding and preserving in native state, and thence forwarded by freight service to near-by markets like New York, and by express service to more remote distributing points.

The lobster is shipped in two forms, *i. e.*, alive and boiled, the form of package and preparation being practically the same. During the warm season, about 25 pounds of ice is placed in the center of a barrel, around which the boiled or live lobsters are packed, an additional 25 pounds of ice being placed on the package. During the cold season, no ice is used, except on packages for destinations in the South. This method has been found to preserve a temperature for the lobsters slightly above freezing point, and will carry them safely for a run of forty-eight hours, when re-icing will be necessary, unless outside temperatures are favorable. The packages above described, when for New York market or distribution, are loaded in refrigerator cars, which are not iced, and are delivered by an over night service at 5.00 a. m. arrival at New York. So far, Chicago is the only outer market warranting regular shipment, there being a carload (by Express) daily from Boston to Chicago. It is well to remark that the barrel containing boiled lobsters must be ventilated, and the lobsters salted as well as iced. A large handler located at Boston is unable to suggest improvements, but to the interested carriers, observing the

efforts of the United States Fish Commission to foster and increase the propagation of lobsters, the opportunity for and likelihood of growth in this tonnage, a field for investigation is opened, yielding increased consumption at more distant markets. In the view of your Reporter these investigations should be directed to the handling of this property in refrigerator cars, iced as for fresh meat, if found necessary. It would appear that this might be accomplished by the use of ice — and — salt mixtures, compounded to produce required frigidity. With these measures should be combined movement on fast freight schedules, making deliveries to markets in the Central West before deterioration of the lobster has begun.

Oysters are offered for shipment in the shell or shelled, in cans, tubs and barrels. Experience has demonstrated the success of handling oysters-in-the-shell, packed in barrels, by freight service, not longer than four or five days to destination, if a temperature from 40° to 50° is maintained. Shipments of shelled oysters by rail are most satisfactorily transported to delivery to consumer when enclosed in sealed cans, packed in boxes with ice; if shipped in contact with ice, there is a loss of flavor. Such shipments are handled entirely by Express service under a temperature between 30° and 35° Fahr., and are satisfactorily delivered from the Eastern Coast to the South and to Colorado. Statistics are not in hand to show the full volume of this movement, although its magnitude may be appreciated from the annual shipment of 3,500,000 bushels, weighing 262,500,000 lbs., from Norfolk, Va., alone. Measures for increasing this traffic are not suggested by dealers. While the oyster is less a luxury than the lobster, it must, with the latter, find increased consumption to a large degree through increase of population educated to its enjoyment. These observations should, of course, be considered as applicable to the development of a movement from all oyster producing coasts in the United States.

CHAPTER VIII.

Beer in kegs.

The present large production of beer, which reaches destination in wood, depends entirely on refrigeration applied to the packages. Refrigerator cars, usually owned by the brewery, are necessary. The kegs tiered in the car to meet the requirements of the market of destination, are topped by 2 to 5 tons of ice, according to distance to be transported, with a mantle or covering of straw. Icing is done by the brewery, because of fast service and special attention to movement which is given by carriers. These arrangements are declared efficient by the brewers, with the suggestion, however, that the possibility of detention en route from accident to track, train or car, should be off-set by arrangements by carrier to stop for re-icing and protection of beer

against fermentation. This suggestion is too pertinent to require emphasis, and doubtless the carriers of beer are already giving this suggestion for necessary protection proper consideration. If from any cause, whether from future shipment in car loads to sparsely settled sections not now receiving in carload lots, or on account of other conditions, the haul should be lengthened, proportionately increased care on the part of carriers will be necessary.

CHAPTER IX.

Conclusions.

Results of observation recorded in the foregoing report pertain largely to the physical handling of perishables by the carriers. Organization and improvement of methods for preparing property for shipment, or for regulating delivery into the actual possession of the carrier; and functions of producer and distributor, and are too comprehensive to receive more than cursory reference in this report.

Protection of perishable property by carrier while in its actual possession through ventilation and refrigeration, has become an obligation on the carrier in respect not only to the necessities of producer and consumer, but to the augmenting of its own traffic and a corresponding increase of its revenue and to such extent is this true that in the United States it has become a legal requirement upon inter-state traffic. Vast populations and large movements, both by handlers and carriers, are, at the present time, almost wholly dependent on the successful discharge of this obligation and your Reporter believes his usefulness measured by the extent to which he can suggest improved ventilation and refrigeration methods.

It is to be regretted that as to ventilation and refrigeration requirements with English-speaking Managements abroad, a failure to receive complete information largely limits your Reporter to suggestions based on prevailing North American practice. However, it is not assuming too much to claim the adaptability of these suggestions to transportation requirements in countries whose barometric and thermal conditions approximate those in North America.

The modern ventilated refrigerator car embodies progress to date in equipment for handling all forms of perishables, and the study of further improvements in its construction and employment as a vehicle for perishables should command the earnest attention of all Managements. The Railroad Refrigerator Service Association of the United States, including in its membership some of the most important rail handlers of perishables, has reduced to a single publication the general principles and rules for caring for perishables handled under refrigeration and ventilation. This publication is known as Circular No. 27, under date 1 July, 1908.

Its perusal is commended. The rules laid down in the circular are for use on all lines members of the Association, and your Reporter presents for consideration the desirability of uniform requirements, particularly where movements cover long distances, with two or more separate managements concerned. The afore-mentioned Association has been organized about two years, and some of its members claim that effectiveness has already been demonstrated. If this claim is supported by the results, it would seem to largely justify the adoption of standard, uniform methods of ventilation and refrigeration, as set forth in circular referred to.

Recommendations have already been recorded in connection with observations on each item of the perishable list. Anticipating their recognition by all Managements in respect to all improvements suggested by ordinary prudence and enterprise, your Reporter especially emphasizes the following suggestions on particular lines :

1° *The thorough expulsion of all heat from highly perishable animal and vegetable substances, before shipment.*

The proved efficiency of this principle, as the developer of a greater traffic, demands that all reasonable persuasion or effort should be used to induce shippers to follow it in preparing their property for shipment. Under prevailing practice in the United States, this recommendation will apply most directly to the fruit and vegetable traffic. Pre-cooling by the Intermittent Vacuum process has, apparently, proved a success, and communication with lines who have it in operation as shown in the preceeding report, for future information as detailed operations, cost, results accomplished, etc., is suggested.

2° *The dissemination, among producers and handlers of all classes of perishables, of any and all suggestions of improvement in methods of preparation, packing hours for delivery to carrier, and reasonable provisions against possible contingencies of transportation and delivery to consumer.*

Illustrative of this suggestion, your reporter calls to the attention of Managements in the United States the exhaustive and instructive experiments made by the United States Department of Agriculture in connection with the methods of picking, packing and shipping the California orange, exhibits from which are introduced in the body of this report. The losses from the decay of California citrus fruits have been variously estimated between $500,000 and $1,500,000 annually. Such losses, if continued, will ultimately reflect on the carrier's interest to a greater or less degree, and the positive results and suggestions made in *Bulletin* No. 123, of the Bureau of Plant Industry, United States Department of Agriculture, should be brought to attention of producer.

It must be clear that the transportation expense, or rate of freight, assessed for

the movement of perishables is a potential factor in the process of developing that particular form of traffic. However, the rate adjustment on perishables in the United States, and in other countries assigned to your Reporter, so far as he has been able to obtain information, is chiefly, if not entirely, fixed by commercial conditions.

To have attempted to obtain and set forth the varying commercial conditions in the various countries, or sections of countries, affecting or likely to affect the rates of transportation, while adding voluminously to the report, might not have been illuminating and might not properly be considered embraced under subject XVI, which reads :

Suitable measures for developing the traffic in perishables : packing, refrigerator vans, appliances for keeping temperature constant, etc.

This feature has not, therefore, been discussed.

---

*

APPENDIX.

Detailed list of questions relating to question XVI.

Perishable traffic, or commodities and substances requiring exceptional handling arrangements to off-set tendency to early deterioration or decay, comprises,

Product of animals :

Fresh meat;
Products of packing houses or abattoirs.

Dairy products :

Eggs;
Butter;
Cheese;
Milk,

Products of agriculture :

Early fruits;
Late fruits;
Early vegetables;
Late vegetables;
Tropical fruits;

Miscellaneous :

Fresh fish and sea food;
Beer in kegs.

Managements addressed are solicited for answers to the following questions, with respect to each of the above designated forms of perishable traffic :

Arrangements for handling.

1. Does the above classification of perishables conform to the practice of rail carriers in your territory; if any additions or eliminations, please indicate?

2. Is the traffic in perishables conducted wholly by carriers for their own account; or is it delegated wholly or in part, to subsidiary agencies corresponding to the so-called express companies operating in the United States, if so, to what extent, and with respect to which of the different items above named?

As explanation of this question; it has been customary in the United States for the railroad companies to contract with so-called express companies, for whose account special equipment such as is used for handling luggage is transported on passenger trains, or trains maintaining passenger schedules. Under these arrangements the express companies assume the entire

responsibility for property so transported, issuing receipts therefore, publishing their own tariffs and from these tariffs making agreed payments to the railroad companies for the facilities afforded. Under American practice these express companies transport generally package traffic in early fruits and vegetables, and sea food, and to some extent fresh meat and ice in local traffic. It is assumed, managements addressed are more or less familiar with the practice and arrangements outlined between express companies and railroad companies, in the United States.

3. Do commodities as listed above originate on the lines of the managements addressed; or do they originate in foreign countries and imported by water? If there any imports, please designate the articles or commodities of foreign origin.

4. Describe climatic conditions, that is, extremes of heat or cold which have to be provided against. Is this provision made by means of accelerated transportation, or by measures to insure constant thermal conditions, or both?

Describe briefly schedules or thermal arrangements, (including description of specially designed cars, vans or wagons) with tables, diagrams or plates and photographs giving graphic descriptions of such arrangements, and detailing results obtained.

As a part of this description, outline methods of packing and storing in cars, vans, or wagons, with illustrative plates or diagrams; if any difference in type of cars, vans, or wagons, assigned to different classes of perishables described, and explain necessity for such difference.

5. Do rail carriers own and operate specially designed cars, vans, wagons or other rolling stock used in transportation of perishables; if not, please give brief outline of arrangements for providing such specially designed equipment, with schedule or tariff of extra charges, if any, assessed against such property for such special service, *i. e.*, charges for icing, use of special cars, etc.?

Do present methods of ownership and operation of equipment for perishables meet the approval of the shipping and receiving public?

6. Do carriers maintain any system of cold storage or other equi-thermal depots or warehouses for the holding of perishables? Is such storage conducted for the purpose of insuring satisfactory condition of traffic transported? For example; is fruit or vegetable traffic placed in such storage house for refrigeration preliminary to commencement of transportation, with the purpose of retarding and preventing deterioration? What does experience teach as to the benefits from such preliminary storage and refrigeration, both to carriers and patrons?

Is such storage system maintained for the purpose of aiding producers to prevent plethoric conditions of the market, insuring staple and remunerative prices?

Please outline briefly views as to the extent that such storage arrangements encourage and promote traffic in perishables?

Charges for transportation.

Obviously, charges for transportation of perishable traffic must be computed, having in mind a cheapening of cost to consumer, as well as remuneration to the carrier.

1. Outline as to each of the items classified as perishable, a brief history of the rates or charges assessed, stating the basis on which such charges were first determined, and subsequent changes which have had the effect of increasing the traffic. Give data obtainable from Boards of Trade

or Merchants Exchanges, showing the increase in traffic directly following, and resulting from rate fluctuations.

2. If special facilities in the shape of storage houses, cars, vans or wagons are provided by subsidiary or independent organizations, to what extent have such organizations had regard to promoting traffic in computing freight rates and charges? In other words, have rail carriers had the co-operation of storage companies and special equipment companies in effort to reduce the price of perishables and increase their consumption?

3. Are special forms of bills of ladings or contracts of carriage entered into for the transportation of perishable traffic; if so, please describe briefly the differences between such bills of lading and bills of lading issued for other forms of traffic.

[625 .244 & 656 .235 .7]

REPORT N° 12

(All countries except those using the English language)

By Richard BLOCH,

CHIEF ENGINEER,

ASSISTANT TRAFFIC MANAGER OF THE ORLEANS RAILWAY

The questions in connection with the carriage of perishable goods are very complex, not only on account of the delicate character of these goods, of the special and varied precautions which they require, but also on account of the many different kinds of such goods that there are. In some, such as meat, there is a regular traffic, in others, such as fruit and vegetables, there is a seasonal traffic; some are produced generally, such as farm produce; others again are localized, such as sea fish; some, like milk, are only carried a short distance, while others, such as eggs and fruit, are also carried long distances, and so on.

It accordingly seems that each of these articles or at least each of the chief groups would require a special monograph, and for this reason the list of questions sent to the different railway administrations included twelve distinct groups.

Actually many of the questions are common to several groups; if therefore this specialization were adhered to in the following report, it would become of excessive length, and there would be numerous repetitions; accordingly we give up this division and shall proceed in this report to an examination of the whole, in which we shall not so much recall the general principles which are known to everybody, but rather draw attention to the particular facts and principles which we collected in the course of our enquiry and which may lead to interesting results or conclusions.

*

In order however to bring back to memory the questions raised in connection with this special traffic, we add as appendix 1 to this report, the list of questions sent to the administrations; following the general order of this list of questions we shall divide our work into the following chapters :

I. — Traffic.
II. — Tariffs and conditions of liability.
III. — Trains and the acceleration of transport.
IV. — Means of conveyance (such as refrigerator vans, constant-temperature vans, etc.).
V. — Settlement of claims.
VI. — Various measures. Packing, etc.
VII. — Propaganda for the development or improvement of the production.

We then propose to follow this general examination by some summary information about certain interesting items which give rise, on the different railways, to special measures worthy of attention. These are milk, sea-fish and flowers.

CHAPTER I.

Traffic.

The information supplied by the different administrations is of a most varied character; some have had none to give, as they keep no statistics, which is a very astonishing fact for enterprises of so commercial a character; others have given more or less detailed information, as contained in the abstracts of their accounts; some finally seem to have compiled special abstracts for the Reporter, for which he has to thank them heartily.

In the case of some railways, we have been able to complete the gaps in their information from other sources, such as the reports submitted to the shareholders, various pamphlets, municipal statistics, etc.

All this different information is very interesting, but to reproduce all of it in this report would take too long, and we have thought it preferable to make it the subject of a special appendix (No. 2) to which we refer our readers.

The first part of that appendix reproduces all the information supplied, on the subject of their traffic, by the administrations who have sent answers on this point; this information was supplemented, where this was possible and likewise interesting, from other sources. The figures have all been reduced, where this was necessary, to metric units.

The countries are classified according to the more special nature of their import or export traffic.

Finally some information is given, taken from the statistics of the Municipal Administration of Paris, of the food supplies of that large city.

A single glance cast on these different tables shows how little useful comparison can be drawn from this information collected from such varied sources; the gaps in certain countries moreover, prevent us from forming a sufficiently accurate opinion of the importance and progress of the traffic in those countries.

For this reason, in order to be able at least to follow the movements of the international traffic, we have utilized the customs returns of the different countries.

Although there is some uncertainty arising from possible alterations which may have been introduced in the method of compiling these statistics, in the distribution of the goods under various heads, changes which are probably the cause of the sudden variations shown in certain traffics, they however give less incongruous information more easily comparable than the railway statistics; in any case they allow us, better than the latter, to follow the flow of the international exchanges which are specially interesting.

The information so collected from the customs returns of the different countries forms the second part of appendix 2. It applies to the countries of continental Europe; however, although England is not included in the scope of our report, we have thought it necessary to give its principal imports and their extent; the importance of the food traffic of that country is in fact so great, it is a matter of such great interest to continental countries, that is seemed impossible to leave it out of consideration even in a paper limited to the latter.

In spite of the want of homogeneity and of the gaps in the information supplied by the railway administrations, a simple examination of it shows that this traffic in perishables is growing everywhere, the increase varying with the increase in the population, with the degree of prosperity of the different countries; but it is everywhere a very remarkable one.

Leaving out of consideration for the moment the international traffic which will be dealt with later, there are certain goods such as milk and sea-fish, which are very important items in the local or home traffic of the different countries; they give a measure of the great increase in this traffic of perishables, and of the interest connected with it.

Taking milk as an instance, we find in the 11 years 1897 to 1907 that the amount brought into Paris increased from 197,684,620 litres to 307,665,401 litres (43,509,729 English gallons to 67,716,133 English gallons); on the lines of the Berlin Directorate of the Prussian State Railway, the amount increased in the 10 years 1897 to 1906, from 155 million litres to 253 million litres (34,115,000 English gallons to 55,684,460 English gallons). The increase during the same period on other railway systems was :

Saxony State, from	50,500	to	86,500 tons.
Bavarian State, from	35,500	—	101,000 —
Baden State, from	24,500	—	55,200 —
Wurtemburg State (1899 to 1906 only), from	33,200	—	67,100 —

As regards fish, the most characteristic results are given below :

Siberian, increased from.	6,000 tons in 1900 to 15,300 in 1906.
Transcaucasian, increased from.	8,300 — — 1902 — 11,000 — 1906.
Russian South Eastern, increased from. . . .	17,200 — — 1897 — 21,100 — 1904 (and decreased 7,400 tons in 1906).
French Northern, increased from	20,400 tons in 1897 to 44,500 in 1906.
French Orleans (from Brittany), increased from .	12,700 — — 1897 — 20,500 — 1908.
Prussian State (Berlin Directorate), increased from	23,600 — — 1897 — 40,900 — 1906.
Saxon State, increased from.	22,500 — — 1897 — 31,000 — 1906.
Bavarian State, increased from	5,000 — — 1897 — 9,700 — 1906.
Baden State, increased from.	1,400 — — 1897 — 3,300 — 1906.

The administrations have been asked to give their opinion as to the causes to which they attribute these increases; very few of them have answered. Those who have done so have generally attributed this progress to the development of the public prosperity and wealth and to the growth of the population, particularly in towns.

The *administration of the Hungarian State Railway* mentions more especially the replacement of cereal cultivation by market gardens which are more remunerative, and, a fact interesting to record, primarily attributes the development in exports to the intervention of shippers of large quantities, resulting in special rebates granted by the railways.

The *Grand Duchy of Oldenburg* mentions the development of the fishing companies.

The *Bavarian State Railway* attributes the increase in the consumption of milk to the anti-alchoolic movement, and to the combinations of producers selling in common.

The particular attention devoted to such articles of food by the railways (quick transit, specially-designed wagons, etc.) and the reduced rates are also mentioned by some of the administrations as causes of their progress.

The examination of the international traffic which can be made by the help of the customs returns, shows, better than these particular statements and these incomplete answers, the fluctuations of this special traffic; they enable us to investigate them more fully.

In order to exhibit more clearly the detailed results given in these tables of appendix 2, we are going to represent them in a series of curves, accompanied by brief remarks.

We shall in the first place examine the import traffic of consuming countries in order to determine to a certain extent the importance and the progress of the demands on the international markets.

The first two diagrams (figs. 1 and 2) show the progress of the total traffic of all the countries considered; as the English and German tonnages far exceed those of the other countries, it has in fact been necessary to give two diagrams, the first on a reduced scale for those two countries, the second for the other importing countries.

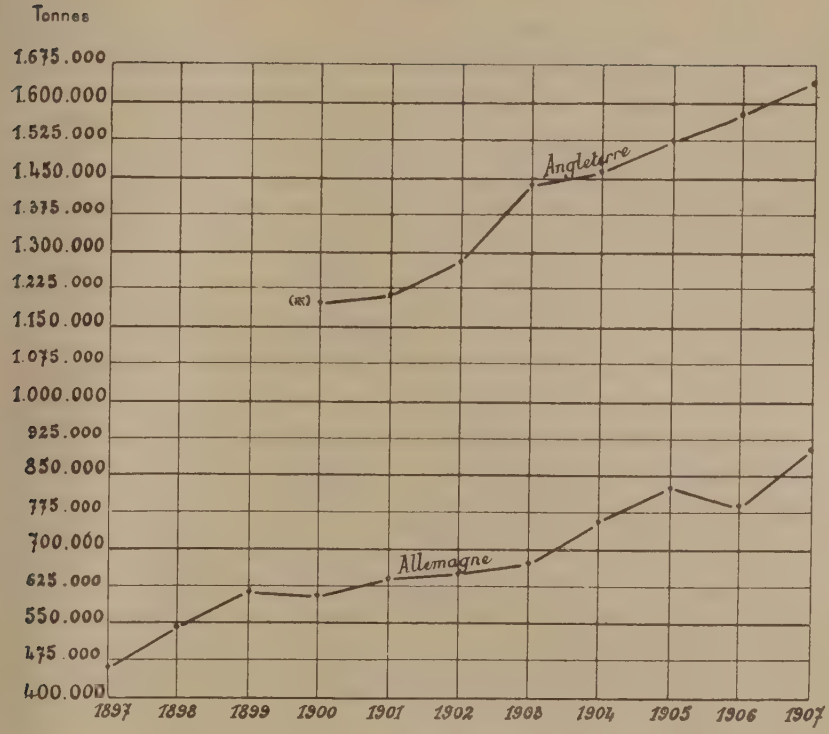

Fig. 1. — Total imports.

(*) Before 1900 the English imports were given in values only in some cases and in volume in others.

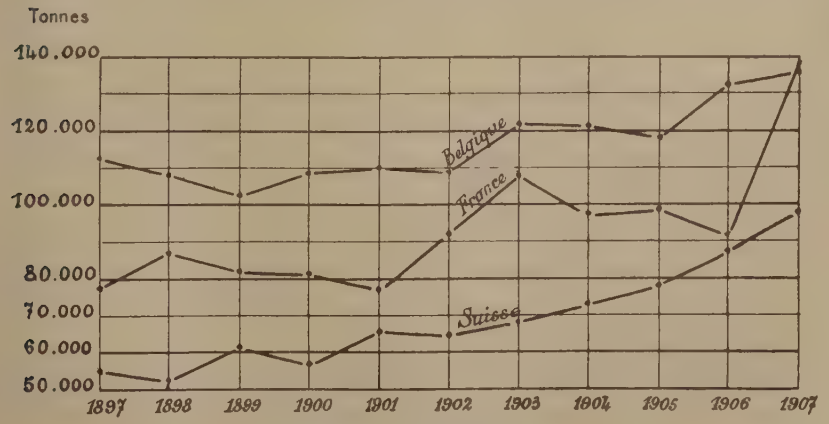

Fig. 2. — Total imports.

Explanation of French terms : Angleterre = England. — Allemagne = Germany. Belgique = Belgium. — France = France. — Suisse = Switzerland.

If we compare the average results of the two last years of the period with those of the two first years, we obtain the differences shown in the following table :

COUNTRY.	Average tonnage of the two years.		Difference.	
	1897/1898.	1906/1907.	+	%
England	1,019,800 tons (1).	1,254,800 tons.	235,000	23
Germany . . .	500,800 —	844,500 —	343,700	69
Belgium	111,100 —	133,700 —	22,600	20
Switzerland	54,500 —	92,400 —	37,900	70
France	82,500 —	113,700 —	31,200	38

(1) 1900/1901.

These curves and the above show the really remarkable increase in the imports into *Germany* and *Switzerland*, increases due no doubt to the industrial prosperity and the growth of population in these two countries, as well as to the continually-growing influx of visitors into Switzerland. This also explains the growing interest felt by the producing nations, principally those on the Mediterranean basin, in their outlets to those two great markets, particularly to the German market which is of course the more important.

In *England* and *Belgium* the traffic has it is true not remained the same, but a period of equilibrium has more nearly been attained.

France, owing to its geographical position, has a double character, being both an importing and an exporting country.

The imports from abroad are often only for supplementary accidental deficiencies in the annual crops; nevertheless a general advance in these imports has to be recorded, an advance due to the increased prosperity and consequently to the growing insufficiency of the home supplies which results from the increased consumption.

After these general considerations, it will be of interest to consider more in detail the progress of the principal items of the general traffic, in order to ascertain which show the greatest advance and which accordingly represent the greatest needs, and consequently attract the special attention of the producers, the merchants and the railways which have to attend to those needs.

The following diagram (fig. 3) shows, from this point of view for the principal continental countries, the progress of the tonnages of our seven groups; a special diagram showing the English imports has been added on account of its interest to the exporting countries of continental Europe (fig. 4).

Limiting our examination to the continental countries, we see that apart from fluctuations due to annual variations in the production, all these traffics are increasing except in the case of fresh meat; the reduction in this is no doubt due to the

protectionist barriers which the different countries erect at their frontiers in order to protect their own produce.

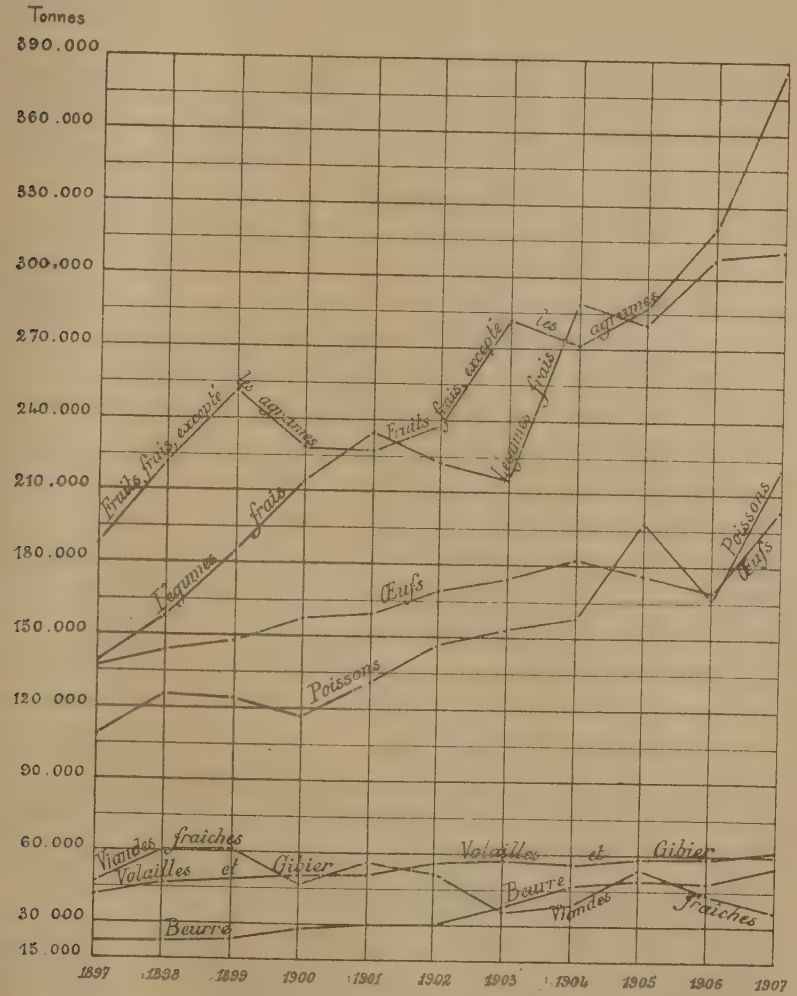

Fig. 3. — Total imports into the chief countries of continental Europe (Germany, Switzerland, Belgium, France), by class of produce.

Explanation of French terms : Fruits frais, excepté les agrumes = Fresh fruit, excluding oranges and lemons. — Légumes frais = Fresh vegetables — Œufs = Eggs. — Poissons = Fish. — Viandes fraîches = Fresh meat. — Volailles et gibier = Poultry and game. — Beurre = Butter.

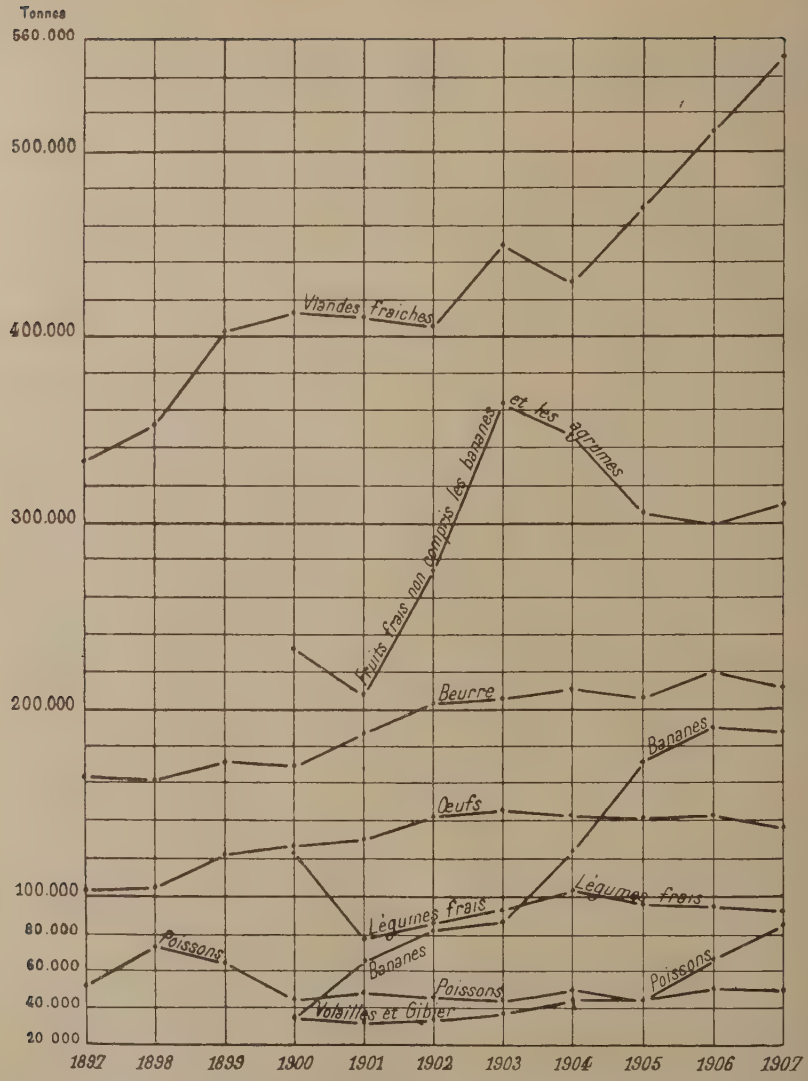

Fig. 4. — Imports into England. — For the periods before 1900, the English returns gave some articles in value or in volume and it has not been possible to compare these figures, with any degree of accuracy, with the figures given from 1900 onwards in hundredweight.

Explanation of French terms: Viandes fraiches = Fresh meat. — Beurre = Butter. — Œufs = Eggs. — Poissons = Fish. — Fruits frais, non compris les bananes et les agrumes = Fresh fruit, excluding lemons, bananas and oranges. — Légumes frais = Fresh vegetables. — Bananes = Bananas. — Volailles et gibier = Poultry and game.

But among all these traffics, it is fruit, vegetables, eggs and sea-fish which show a preponderating importance and great progress.

The extent and growth of the needs which are thus exhibited, account for the energy which the exporting countries bring to bear on the development and increased production of these articles, making of these special traffics really a national matter.

Thus this national interest explains why Italy stipulated for increased facilities for its fruit traffic, when the convention of 20 April 1909, for the repurchase of the St. Gothard Railway by Switzerland, was agreed to by Switzerland, Germany, and Italy.

A still more characteristic instance of this prepossession in favour of a public interest is shown in the very instructions issued by the Italian State Railway to its employees.

Thus in the preamble to secure order No. 111 of 25 November 1906 concerning the routes to be followed by wagons containing perishables, we find this phrase:

And as it is a question of an industry of an eminently national character and interest,

The subsequent orders 63 and 125 of 1907 contain on the same point :

On this occasion, we once more strongly recommend all the employees to observe the fixed rules... and to take the greatest possible care in effecting these transports, as they are of evident importance to the national economy.

Finally, the last service order No. 72 which summarizes and replaces all the previous ones, is of special interest, not only because it emphasizes this point of view of the national interest, but because it introduces the principle, of which we will see the development later on, that the existence and the progress of this traffic in agricultural produce depends essentially on the speed of conveyance :

The present regulations are chiefly devised to ensure the quick transport of articles of food in large quantities from their place of production to the consuming markets, principally the foreign ones; this is an essential condition for the existence and extension of the agricultural produce industry which is of national interest.

An equal activity, combined by the same feeling of the importance of these traffics to the national interest, is shown by Germany in the case of its fisheries, by Bulgaria in the case of its eggs, by Russia and in Denmark in the case of their eggs and butter, and by France in the case of all its produce.

The preceding curves have shown us the nature of the produce principally required on the European markets; we will now consider how these demands are distributed between the different countries and determine in which the demand is greatest.

This we will do by means of the curves given below; these will show the progress in the different importing countries, for each of the groups of produce considered.

The quite exceptional imports of England having already been shown in a previous figure, these new curves will be limited to the continental countries.

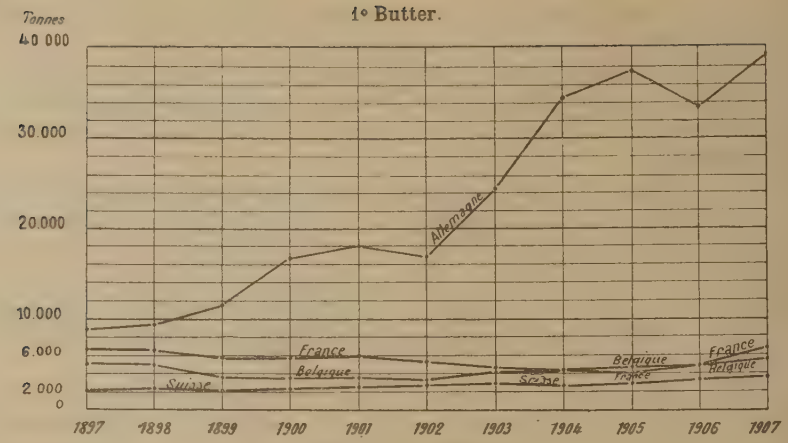

Fig. 5. — Butter.

Germany alone shows a particularly active and growing market. In France the quick increase in home production makes the import curve undulate.

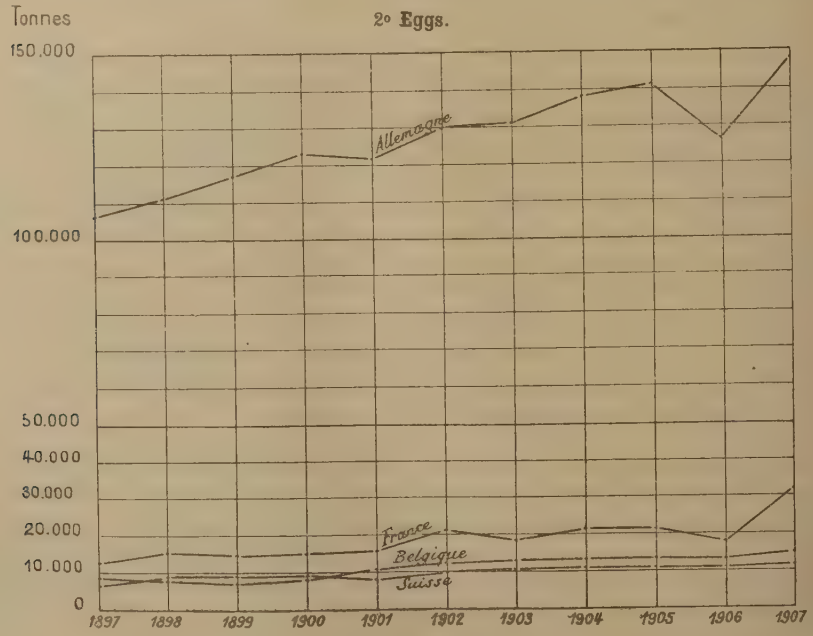

Fig. 6. — Eggs.

Explanation of French terms: Allemagne = Germany. — France = France. Belgique = Belgium. — Suisse = Switzerland.

Here again German imports are very important and are growing very appreciably, while Belgium and Switzerland only show slight variations. Taking the population into consideration, French imports are of comparatively minor importance, but yet show an appreciable increase.

3° **Fresh meat.**

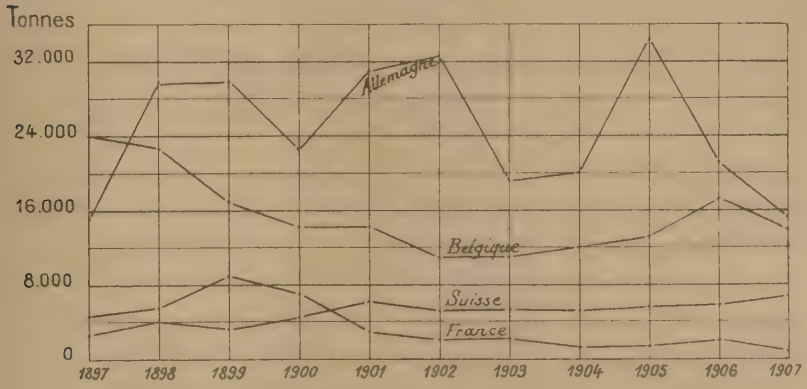

Fig. 7. — Fresh meat.

Explanation of French terms : Allemagne = Germany. — Belgique = Belgium. Suisse = Switzerland. — France = France.

As compared with the general progress in the case of the other perishables, the small increases, the decreases even in the fresh-meat imports, show the efficiency of the measures of protection taken by different governments against these imports; but it may be thought that they also depend on the special difficulties involved in carrying these very perishable articles when using the ordinary railway rolling stock.

The very considerable growth in these imports in the case of England is in fact not due only to fewer restrictive measures in that country, but above all to the development of refrigerating machinery on the ships carrying this traffic.

At every time of year, in spite of the long time required for the sea voyages, this very delicate article of food is at present safer on board ship, however long the journey, than on ordinary railway rolling stock, during the hot season, in spite of the shortness of the journeys.

4° **Poultry and game.**

Here again the German traffic is much the most important and is increasing very markedly. In that country the customs returns distinguish between small animals which are alive and those which are dead, and we have given two corresponding curves as it seems to us they lead to an interesting observation confirming the final remark of the last article.

These curves show indeed the remarkable disproportion between these two traffics and the much greater importance of the traffic in live animals. Now it is a priori evident, that in spite of quicker transport, in spite of the care taken in providing food and drink in their cages, these small animals, when packed into wagons which are as fully loaded as possible, must certainly suffer and lose some of their weight and their quality.

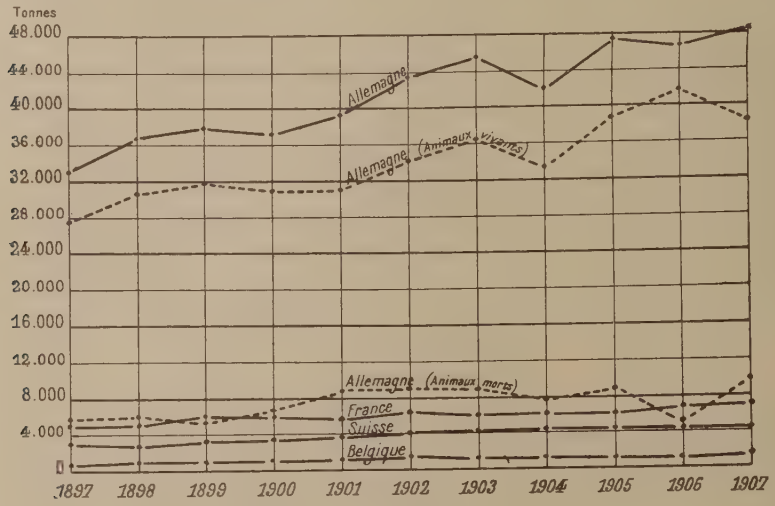

Fig. 8. — Poultry and game.

Explanation of French terms: Allemagne = Germany. — Allemagne (animaux vivants) = Germany (Live animals.) Allemagne (animaux morts) = Germany (dead animals). — France = France. — Suisse = Switzerland. — Belgique Belgium.

Why then is it that such carriage is preferred to that of dead animals, if it is not that in the case of these small and delicate animals, still more than in the case of fresh meat, the use of ordinary railway rolling stock does not give enough security?

The answer of the Bavarian State Railway moreover, refers summarily to these difficulties by stating that the traffic in dead poultry is stationary because *its transport is disadvantageous from many points of view.*

5° Fish and shell-fish.

Important though these imports may be, particularly in Germany, they only give a very incomplete idea of these special articles of consumption and of the important traffic which results. It is in fact evident that the supplies in each country are in the first place found by its own boats, so that the curves shown would require to be supplemented by the yield of the national fisheries; now this amounted in France to

130,400 tons in 1897 and to 195,900 tons in 1907, sardines and shell-fish not included; while in Germany it earnly doubled the total tonnage of fish carried on the railways, from 234,700 tons in 1897 to 451,600 tons in 1907.

Special attention is drawn to the importance of these imports into Belgium, taking into consideration the smaller population of this country.

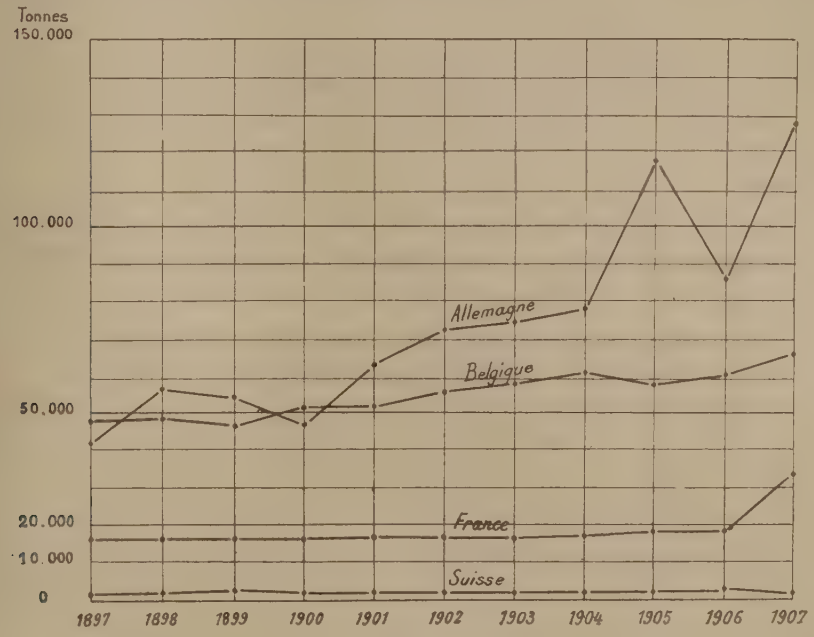

Fig. 9. — Fish and shell-fish.

Explanation of French terms : Allemagne = Germany. — Belgique = Belgium. France = France. — Suisse = Switzerland.

6° Fresh vegetables.

It is evident that in the cases of Switzerland and Belgium, the smaller populations of these countries have to be taken into consideration in this comparison, just as in the last case; it must however be recognized that this traffic is not affected by appreciable fluctuations there; on the other hand France, which exports more than it imports, generally has enough for its own proper consumption; this traffic thus is of special interest in Germany alone and it is evident what great progress there is there, for the tonnage of the imports increased from 97,200 tons in 1897 to 208,700 tons in 1907; thus it became more than doubled.

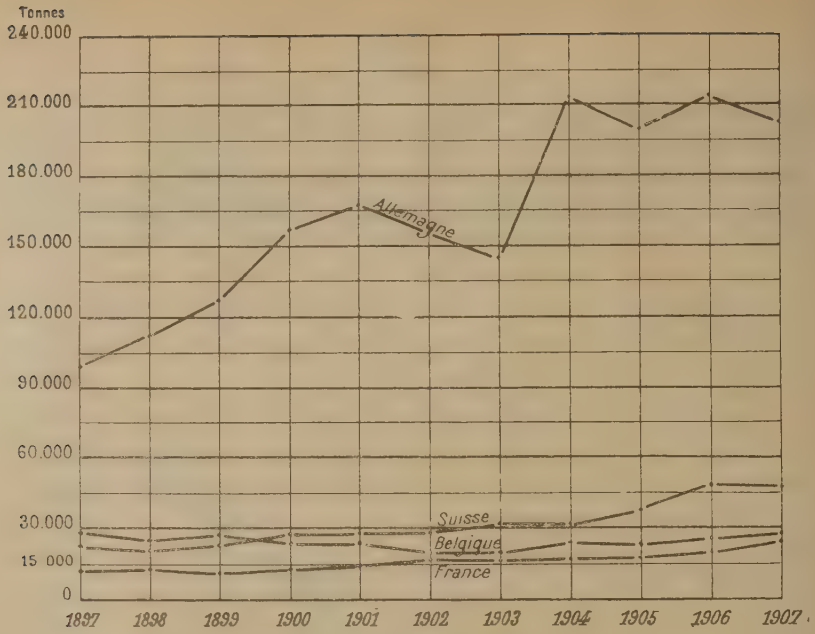

Fig. 10. — Fresh vegetables.

Explanation of French terms : Allemagne = Germany. — Suisse = Switzerland.
Belgique = Belgium. — France = France.

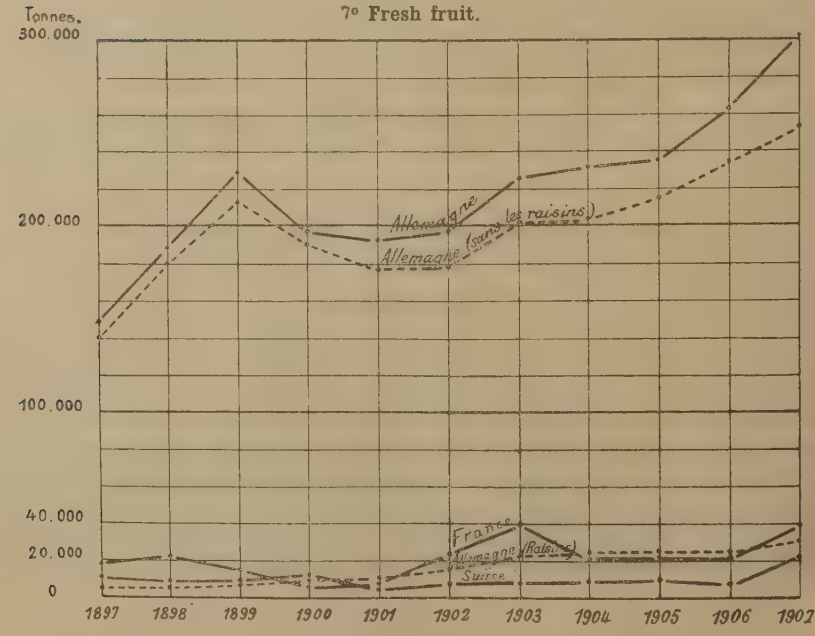

Fig. 11. — Fresh fruit.

Explanation of French terms : Allemagne = Germany. — Allemagne (sans les raisins) = Germany (grapes excluded)
France = France. — Allemagne (raisins) = Germany (grapes). — Suisse = Switzerland.

The consumption of this article in Germany, just as in the case of the preceding articles, is seen to increase, almost to double, as far as fruits other than grapes are concerned; for it increased from 141,600 tons in 1897 to 269,000 tons in 1907. As regards grapes for eating at table, a real article of luxury, the consumption was quintupled; it rose from 7,000 tons in 1897 to 35,400 tons in 1907.

This consumption increased still further in 1908, in spite of the slump which afflicted the industrial world. The following table shows the share and the progress of this grape business of the different countries producing them.

—	1905.	1906.	1907.	1908.
	Tons.	Tons.	Tons.	Tons.
Italy	11,600	12,400	17,300	22,700
France	5,100	7,800	10,400	10,400
Algiers	100	1,000	500	900
Spain	2,700	3,400	5,100	3,700
Austria-Hungary	1,100	1,000	900	1,200
Other countries	1,500	1,000	1,200	1,000
Total	22,100	26,600	35,400	39,900

The data given in appendix 2, together with the curves representing them, well define, we think, the condition of the European market as regards perishables. It shows clearly that besides England, Germany, on account of the progress of its population and of its wealth, has become an important market for such produce; this market is growing quickly and without interruption, and attracts large quantities of produce of a most diversified character, produce of farms, of kitchen gardens and of orchards.

Looking at it now from the other side of the question, it is interesting to see how these imports are divided among the different producing countries; and to what extent, and in what lines, each of them contributes to the supplying of these great markets of consumption.

The statistical tables in appendix 2 enable us to get a general view of this; but as in the case of imports, it appears preferable to condense the figures shown in these tables and to represent them in the form of curves which appeal more to the eye and make more evident the differences between the results as well as the conclusions to be drawn from them.

The examination of this diagram (fig. 12) suggests a number of general observations which seem worthy of attention.

In the first place one is struck by the great difference of the results obtained in Spain as compared with other countries. The climate and conditions are however much the same as say in Italy or the Danubian countries; yet exports are much smaller.

It is also to be noted that of the total 88,500 tons in 1907, 18,400 tons only, that

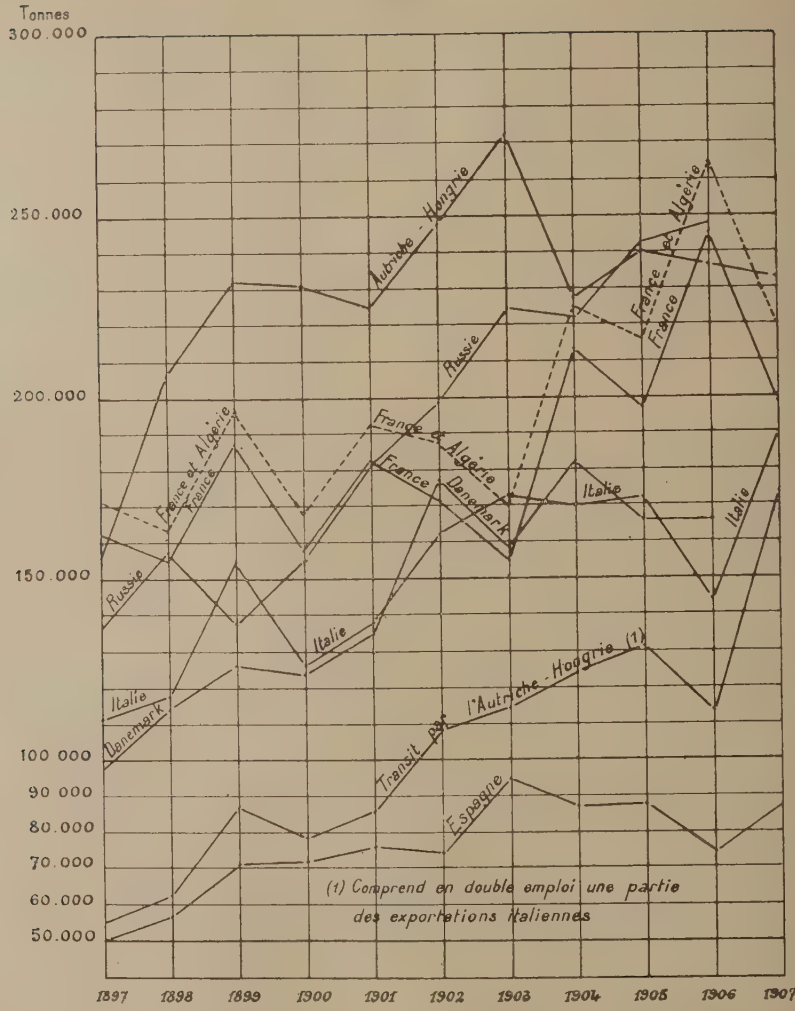

Fig. 12. — Total exports of the chief exporting countries of continental Europe.

Explanation of French terms: Autriche-Hongrie. = Austria-Hungary. — Russie = Russia. — France et Algérie = France and Algiers. — France = France. — Italie = Italy. — Danemark = Denmark. — Transit par l'Autriche-Hongrie (1) = Balkan countries and Turkey. — Espagne = Spain. — (1) Comprend en double emploi une partie des exportations italiennes = Part of the Italian exports are counted twice over.

is to say an insignificant amount, were exported across the frontier by the French railways, while the rest, which consisted chiefly of the special Almeria grapes, was forwarded by sea.

Such an inferiority is no doubt to be attributed to the fact that in Spain the government and the railways are occupied by other matters, and have not yet devoted any special attention and special measures to this interesting branch of production, without which it cannot become developed; while in other countries the contrary has been the practice.

Here this development also depends on the assistance of the French railways; but the European market is big enough to absorb everything and moreover, owing to the difference of the seasons, the Spanish harvest could not affect French production which it would on the contrary supplement; the French railways would thus have a real interest in giving the assistance which they have actually spontaneously offered.

However this may be, the comparison of these results give this proof, should any be necessary, of the importance to this special traffic of the marked attention usually devoted to it by the railways; without it, not only could it not prosper, but it could not even exist.

In order to show more clearly the results obtained by comparing the curves of the different countries, from another point of view, we give in the following table the average results of the two first and of the two last years of the period considered.

—	1897 1898.	1906 1907.	Difference.	
			+	%
Russia	159,900	258,100 (1)	98,200	61
Denmark	105,600	166,600 (1)	61,000	58
Austria-Hungary	182,500	232,200	49,700	27
Balkan countries	59,100	143,600	84,500	143
Italy	114,400	167,800	53,400	47
Spain	54,400	81.600	27,200	50
France	168,300	242,200	73,900	44
Total	844,200	1,292,500	447,900	53

1905/1906.

Now only Denmark and Russia and above all the Balkan States, the most recent participators in this special traffic, show increases which exceed the mean; this according to a judicious remark made by the administration of the Hungarian State Railway, is because the development of industry and of wealth, the growth of population, in old countries such as Austria and Hungary, and to some extent Italy, determine the increase in home consumption to the detriment of the exports; a similar change is observed in France, where as we will see, the export of butter and

*

eggs, for instance, is decreasing, while the imports, particularly of eggs, are on the contrary increasing.

If this point of view be correct, the distance of the producing countries thus increasing, the distance the consignments have to be carried naturally tends to increase also; because owing to the delicacy of these goods the railways have continually to take more care and to increase the speeds, so that these perishables may be brought in a good state of preservation to more and more distant markets.

Finally, if we examine the progress of exports from France and Italy to England and Germany, we arrive at a singularly instructive conclusion.

In the two latter countries, the values given by the customs for French fruit are generally higher than those for Italian (1), and although France almost monopolizes the English markets as regards European fresh fruit (except as regards grapes), yet its sales in Germany but a few years ago were nearly nil, and that country was supplied with fruit by Italy nearly exclusively.

Now of late French trade has on the contrary grown largely as the following table shows :

YEARS.	Grapes for the table, cherries and other stone fruit.				
	Total.	from France.		from Italy.	
1900	21,600	2,400	11 %	11,100	51 %
1901	24,200	1,900	8 %	15,200	63 %
1902	29,500	4,100	14 %	20,600	70 %
1903	29,500	1,600	5 %	20,800	71 %
1904	39,200	6,300	16 %	22,600	58 %
1905	34,900	9,000	26 %	16,500	47 %
1906	38,400	11,000	29 %	17,700	46 %
1907	53,400	16,800	31 %	24,800	46 %
Increase from 1900 to 1907.	31,800	14,400	...	13,700	...
	147 %	600 %		123 %	

Now why did Italian fruit which found no appreciable market in England on the contrary have such an extensive sale in Germany? And also why is French fruit making such a rapid progress in the latter country, after such a long abstention?

The quality can not be the only reason; nor can the question of distance; besides the western districts of Germany are nearer to the French centres of productions than to the Italian centres; England takes more fruit from Spain than from Italy although the transport takes longer and costs much more.

But here other considerations arise; the business in fruit and fresh vegetables is

(1) Values according to the estimates of the German customhouse in 1904, in marks per ton

ARTICLE.	*France.*	*Italy.*
Grapes for the table	480 Marks.	340 Marks.
— for wine making	233 —	175 —
Stone fruit (other than cherries)	635 —	400 —
Fresh vegetables	642 —	180 —

carried out by telegram between firms which must know each other and have a mutual confidence in each other; now while the German Italian relations facilitated by the opening of the St. Gothard had become more strained for political reasons, the contrary was the case as regards Franco-German relations; an approach which seems to have taken place in the last few years has at once been followed by an increase in this special traffic.

We may conclude from this comparison that in order to develop the trade in perishables to the fullest extent, it is necessary to try to facilitate as much as possible the relations of individuals, and to accelerate and cheapen their means of communication.

After these general considerations and as a counterpart of the analysis made above of the needs of the consuming countries, we will now investigate, in the case of the chief exporting countries, of the European Continent, how the general export traffic is divided between the different groups of goods; then extending the analysis and studying for each group the participation of the different exporting countries, we shall be able to show the situation of the different producing markets, and, for each of the groups, the existing tendencies in the different countries.

The results shown by these curves (fig. 13) agree in a general way with those of the import curves of the chief countries of the European continent and of England; the differences observed are naturally caused by limiting this study to a certain number of countries, or else it would have become too long; thus for instance as regards sea-fish, the important exports of Germany, Holland and Belgium, are omitted, and as regards fresh vegetables, the exports of Holland, which on the other hand figure in the total imports of the consulted countries.

But allowing for this, and also allowing for the uncertainties which result from the different systems of classification adopted by the customs authorities in the different countries, from the greater attention they naturally devote to imports than to exports, it may here again be recognized that the future of this traffic in perishables chiefly affects eggs, vegetables and fresh fruit.

Butter, which contributes a fairly large tonnage, is *above all, as we have seen, intended for England or for Germany;* the bend in the curve shown by this article is it is true in contradiction with the observed progress of these imports into Germany; but the anomaly is above all due to the increase in the supplies sent from the English colonies, Australia and New Zealand, which have partly replaced continental produce in England.

The tonnage of these imports from the colonies oversea increased from 15,700 English tons (of 1,015 kilograms each) in 1895 to 23,000 tons in 1905 and to 45,100 tons in 1907.

It would also be necessary to take into account the exports from Holland as far as this special trade is concerned.

Finally, we find the same uncertain and inactive movements in the fresh meat

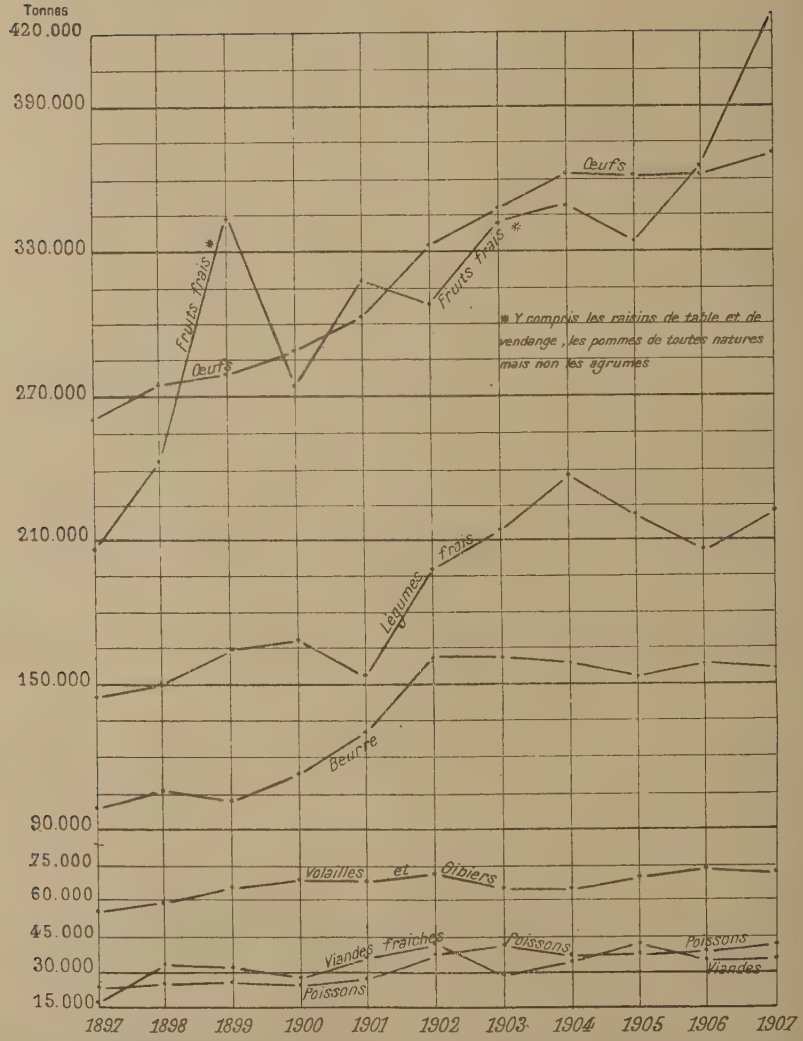

Fig. 13.* — Total exports of the chief countries of continental Europe (altogether). Russia, Denmark, Austria-Hungary, Balkan countries and Turkey, Italy, Spain, France (with Algiers). By class of produce.

Explanation of French terms : Œufs = Eggs. — Fruits frais* = Fresh fruit*. — * Y compris les raisins de table et de vendange, les pommes de toutes natures mais non les agrumes = * Including grapes for table and for wine-making, and apples of all kinds; but excluding oranges and lemons. — Légumes frais = Fresh vegetables. — Beurre = Butter. — Volailles et Gibier = Poultry and game. — Viandes fraîches = Fresh meat. — Poissons = Fish.

traffic, and in the poultry and game traffic, traffic which is hindered by the great delicacy of these goods, by the deficiencies of the rolling stock used to carry such goods, and as regards meat in particular by the customhouse or sanitary restrictions which some countries put in the way of these imports.

In the diagrams which follows we will examine the shares of each country in these different exports.

1° **Butter.**

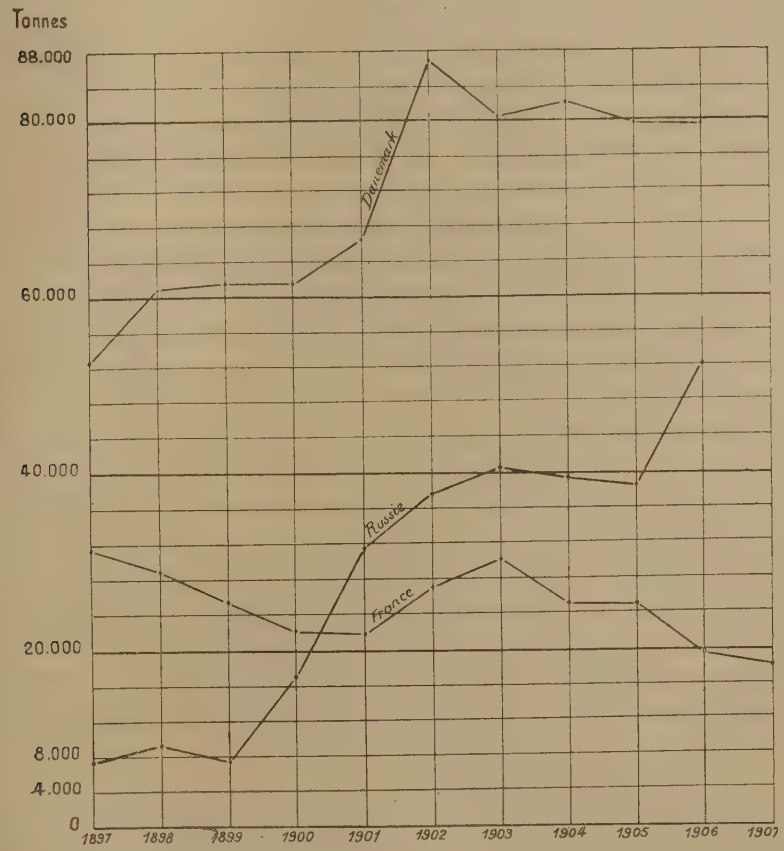

Fig. 14. — Butter.

Explanation of French terms: Danemark = Denmark. — Russie = Russia. — France = France.

We took the opportunity, in discussing the last diagram, to explain the general state of this butter traffic, and how the exports of European countries now had as

competitors, at least in the English market, produce sent from the distant countries of Oceania.

The Russian traffic, the remarkable progress of which was momentarily suspended, in 1904-1905, by the Russo-Japanese war, consists nearly wholly of Siberian butter. In chapter IV, we shall see that the remarkable progress in this traffic is due to the refrigerator vans which are used for the very long journeys, just as that of Australian butter is entirely due to the use of refrigerators on board ship.

On the other hand, the growth of the prosperity in European countries, such as France for instance, results in an increase in the home consumption which naturally limits the amount left available for export.

2° Eggs.

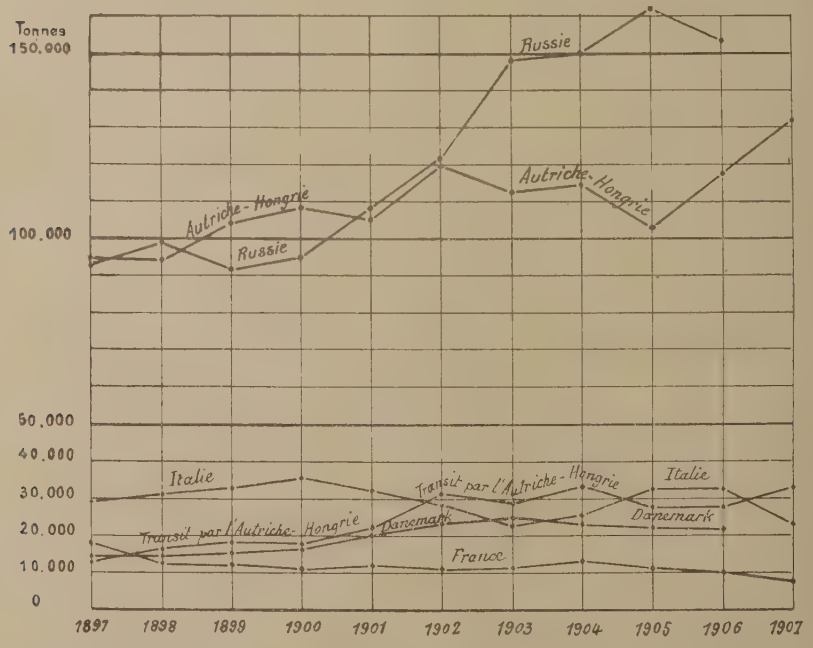

Fig. 15. — Eggs.

Explanation of French terms : Russie = Russia. — Autriche-Hongrie = Austria-Hungary. — Italie = Italy. Transit par l'Autriche-Hongrie = Transit viâ Austro-Hungary. — Danemark = Denmark. — France = France.

In the case of eggs as in that of butter, the traffic of the countries which were formerly exporting countries, such as Italy and France, varies under the double influence of the development of home consumption and the competition of more distant countries; above all Russia and, in particular, Siberia, have more and more

tendency to supply the European market and to their influence is no doubt due the slackening which has of late years been observed in the progress of the exports from Denmark and from the Danubian countries.

3° Fresh meat.

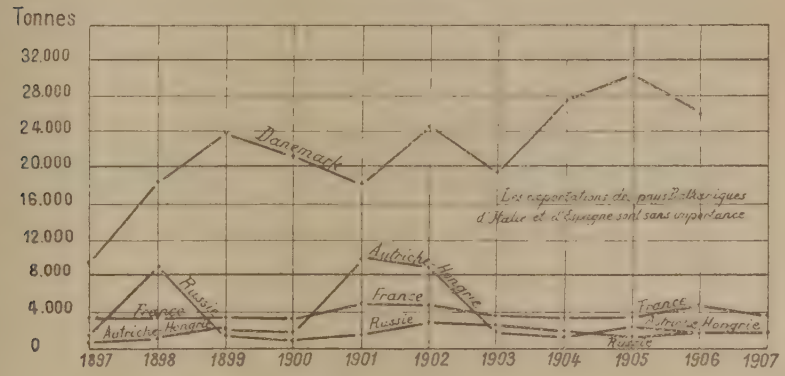

Fig. 16. — Fresh meat.

Explanation of French terms : Russie = Russia. — Autriche-Hongrie = Austria-Hungary. — Italie = Italy. — Transit par l'Autriche-Hongrie = Transit viâ Austro-Hungary. — Danemark = Denmark. — France = France. — Les exportations des pays Balkaniques, d'Italie et d'Espagne sont sans importance = The exports from the Balkan States, Italy and Spain are unimportant.

As we have already explained, this international traffic is hampered by the customs or sanitary restrictions of the different countries, and therefore cannot expand fully; moreover, it requires a special transports organization with an improved rolling stock, an organization which is generally not in existence at present.

The Danish exports however are an exception to this general rule. Their development is due above all to the increase of pig-keeping in that country; this development is in direct connection with the dairies because all the secondary products of the latter are used for feeding the pigs.

4° Poultry and game.

As appears only natural, the traffic in poultry and game follows to a certain extent the same path as that in eggs.

Russia however shows a much moremarked superiority than in the latter traffic; this may depend on a smaller home consumption.

If we examine the customs returns we make the same observation as when we studied the imports, that is to say the transport of living animals in much the more important item.

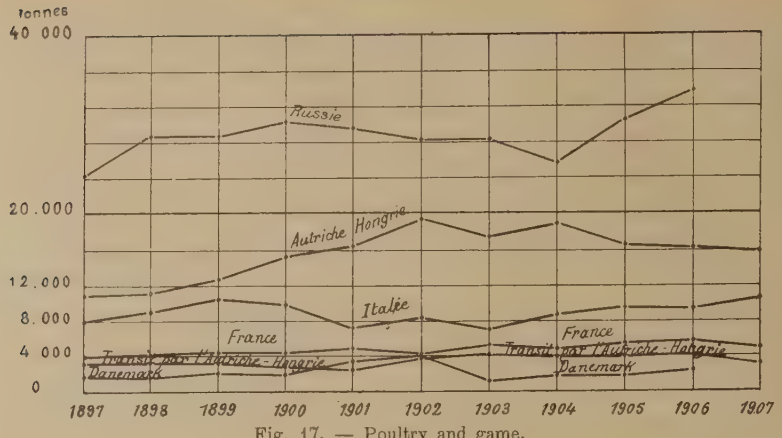

Fig. 17. — Poultry and game.

Explanation of French terms : Russie = Russia. — Autriche-Hongrie = Austria-Hungary. — Italie = Italy. France = France. — Transit par l'Autriche-Hongrie = Transit viâ Austro-Hungary. — Danemark = Denmark.

Thus the Russian export statistics for 1906, according to numbers of animals, shows :

Live poultry	2,961,871 head.
— geese	6,395,632 —
Dead poultry	499,769 —

We think this difference is to be explained, as before, by the special difficulty of conveying these comparatively-expensive and eminently-perishable articles by means of the ordinary rolling stock.

On the other hand it appears from information recently submitted to the International Refrigeration Congress (Paris, October 1908), that the preparation and the preservation of dead poultry are carried out in Russia under very defective conditions. The measures applied and the results obtained in the case of butter seem to indicate what road to follow.

5° Fish.

This diagram is limited to the countries which share most largely in the total perishables traffic and does not include certain countries the exports of which are, at least as far as fish is concerned, of special importance; namely Germany, Sweden and Norway.

Besides, the international traffic is, as we have already shown, quite out of proportion to the home traffic of each country supplied by its national fisheries, and it is the latter traffic which is more specially worthy of attention.

However that may be, this traffic shows an important increase in Denmark, and a very appreciable one in France, so well favoured by the extent of its coast; and for this reason it would seem that it should show a much greater activity.

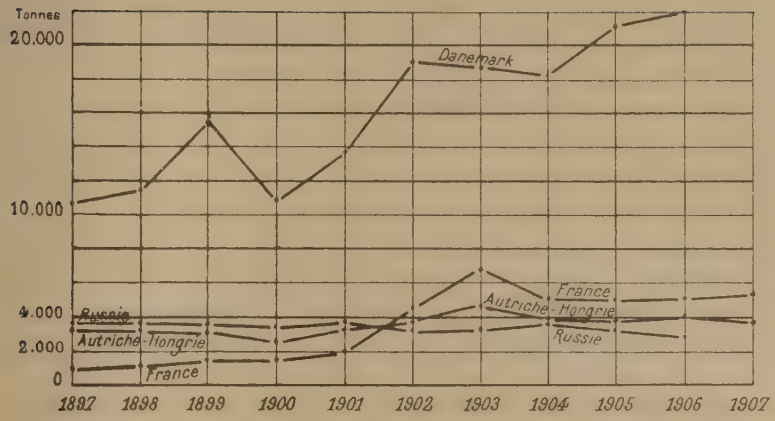

Fig. 18. — Fish.

Explanation of French terms : Danemark = Denmark. — Russie = Russia. Autriche-Hongrie = Austria-Hungary. — France = France.

6° Fresch vegetables.

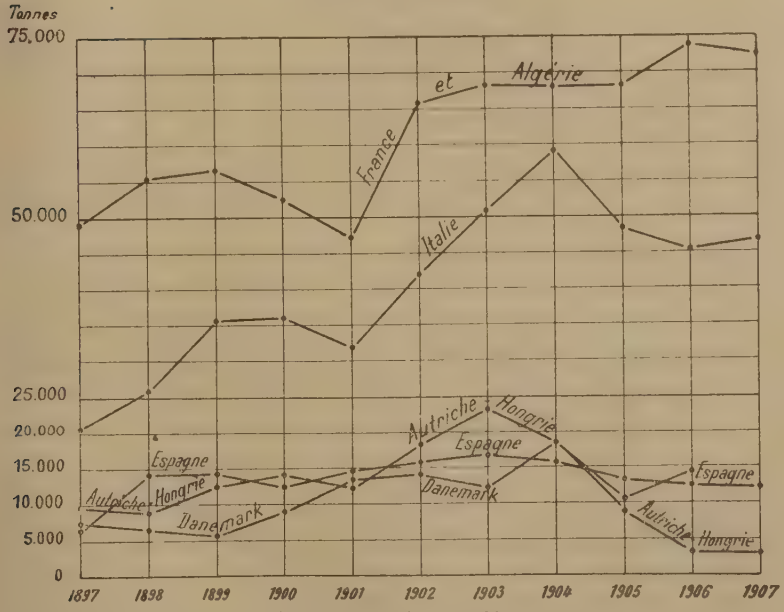

Fig. 19. — Fresh vegetables.

Explanation of French terms : France et Algérie = France and Algiers. — Italie = Italy. Espagne = Spain. — Autriche-Hongrie = Austria-Hungary. — Danemark = Denmark.

This curve (fig. 19) again shows the weak position of Spain as compared with Italy. The latter country really shares with France the European markets for high-class and early vegetables.

In order to obtain a complete idea of this traffic it would be necessary to add the very important exports from Holland where market-gardening is very highly developed and which supplies the industrial districts of West Germany to a large extent.

These Dutch imports of fresh vegetables into Germany have increased very rapidly of late years; they amounted to 15,200 tons in 1885, to 45,400 tons in 1895 and to 113,100 tons in 1905.

If on the other hand we compare the progress in France and Italy, taking the average of the first two and of the last two years of this period, we obtain the following table :

—	1897/1898.	1906/1907.	Difference.	
			+	%
Italy.	22,750	45,950	23,200	102
France	49,400	72,200	22,800	46

7° **Fresh fruit.**

The vicissitudes of this special traffic exhibited by the summits and hollows of these curves depend on the variations in the annual harvests both in the exporting and in the importing countries.

Thus we see in France for instance the effect of the two exceptionally-bad years 1902 and 1903.

But these variations themselves vary in the different districts, and it is curious to note on the diagram how frequently the summits of certain countries correspond to the hollows of others, in other words, how the surplus in the former counter balances the deficit in the latter.

It is for this reason no doubt that in the general diagram (fig. 20), which represents the resultants of these different movements, the curves representing the total traffic show much less irregularity, and show a nearly continuous movement in advance.

These irregularities in the annual yield of the different countries, the limited period of time during which such consigments are sent, the particularly-delicate nature of these goods whose value depends mainly on their transport, have as result that of all the perishables, it is perhaps the fruit traffic which gives the railways the most difficulties and which they have to take most cares over.

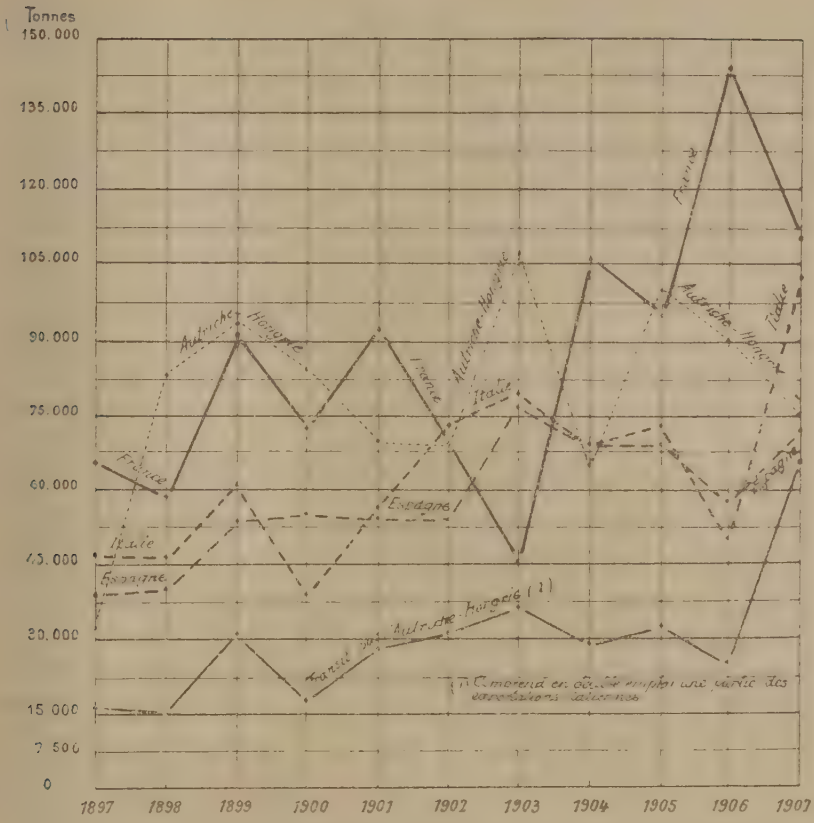

Fig. 20. — Fresh fruit, including grapes for the table and for wine-making, apples and strawberries; but excluding oranges and lemons.

Explanation of French terms : Autriche-Hongrie = Austria-Hungary. — France = France. — Italie = Italy. — Espagne = Spain. — Transit par l'Autriche-Hongrie = Transit viâ Austro-Hungary. — Comprend en double emploi une partie des importations italiennes = Part of the Italian exports are counted twice over.

SUMMARY.

Summing up this detailed analysis of the conveyance of perishables on railways we find that as a general rule these traffics are growing rapidly in consequence of the more general prosperity, of the increase in wealth and in population, of the greater and greater facilities given by the administrations, the details of which we will consider later on.

This progress is especially striking in the case of produce such as fruits and

vegetables, where the different countries in a way supplement each other, and the importation of which consequently does not meet with any serious opposition.

The same applies to farm produce, butter and eggs, the demand for which in industrial districts exceeds the amount which can be produced in those districts and makes it necessary to draw upon more and more distant countries.

In the case of sea-fish and of meat, on the contrary, attempts are everywhere made to protect the national produce; moreover in the case of meat more especially (and this is equally applicable to poultry), as it is no longer, as in the case of fruit, a question of produce which is worth very little where produced and which consequently one exposes without too hesitation to the risks of transport; for meat is an article of considerable value at the points of production already, and is very perishable; consequently the producer has but little desire to expose it to the risks of loss inherent to distant conveyance in rolling stock which is not perfectly suitable.

Hence more especially those important transports of live poultry which certainly cannot arrive at its destination without loss of quality and loss of weight, but which nevertheless arrives alive and still saleable; while with dead animals there is the risk of receiving spoilt goods unfit for consumption.

All this traffic in perishables, the importance of which has been shown in this paper, its progress and its development depends in short exclusively on the care taken in the conveyance.

The examination of the measures taken for the purpose by the different administrations as well as the improvments still to be desired will form the object of the subsequent chapters.

CHAPTER II.

Tariffs. — Rates and conditions of liability.

The heading of this chapter includes the two questions of the rates and of the liability of the railway, because they seem in fact interconnected to a certain extent on some of the railways, and because taken together they have to be considered from two entirely-different points of view.

Some administrations, considering the difficulties of the carriage of perishables and the extent of the risks run, try to escape those risks by offering the public reduced rates in exchange for limitations of liability.

Others (up till now only the French ones) take the opposite point of view; admitting that these perishables acquire nearly their whole value from the conveyance itself, they consider that a guarantee of proper arrival is by far the most important

consideration. Consequently they have decided to undertake this responsibility and to devote their efforts and their sacrifices to the acceleration of the conveyance, while on the other hand keeping their rates higher.

This essential difference between the points of view is certainly one of the causes of the differences observed between the tariffs of different countries, and it is evident how important it is to understand this difference when we are going to consider the question of the rates themselves.

Let us in the first place examine these two systems from the point of view of the trade and of produces.

As railways are naturally servants of the public, it is the opinion of the interested parties which has chiefly to be considered.

Now we find a sincere and recent expression of the wishes of the trade concerned in the minutes of an important commission which was appointed in France in 1905 to examine the question of the carriage of perishables. This commission included not only representatives of the railways, but also representatives of this special trade and of the producers, parlementarians and officials.

If we look through the minutes of the meetings, the reports and papers submitted by the parties concerned, we are struck by the small attention given to the rates themselves, and on the other hand by the great and significant attention given to the questions concerning the time to be allowed for the conveyance and above all to the responsibility of the railways to adhere to that time.

The nature and the extent of these considerations will be made very clear by the following extracts from these minutes :

Meeting of 11 November 1905 :

Mr. Omer Decugis, president of the " Chambre Syndicale des Commissionnaires en fruits et en primeurs" thinks :

" That we (in France) are advancing, and that if the railway companies will guarantee shorter times of conveyance to the consigners, which is *the great question*, we will easily find outlets."

At the same meeting, later on, Mr. Buisson, President of the *Syndicat des Mandataires à la vente en gros des fruits et primeurs*, made the following statement :

" The question of the time of conveyance is the paramount question : it matters but little to the producer to know under what conditions his goods are carried if these do not arrive in good time for their sale. In the case of early vegetables and fruit, twenty-four hours more are enough to make them unsaleable. At present when the producer consignor ascertains what the time of conveyance is, the information supplied by the despatching station is only an expression of probability and if the goods arrive damaged or too late the party interested has no claim against the company."

Mr. Buisson concluded by demanding that the carriage of perishables should cease to be

a matter of probability and *that the companies should be made liable in case of any delay. He proposed that this question of time should be placed at the head of the agenda.*

Meeting of 29 November 1905 :

Mr. Jouillat. President of the *Chambre Syndicale des Mandataires à la vente en gros de la volaille et du gibier aux Halles Centrales de Paris*, observed :

" The parties interested do not complain of the times occurring in practice when they are short. *They complain of the legal times, which are excessively long, behind which the companies shelter themselves when their service is irregular.*"

Similar wishes are expressed in other countries; they are more especially mentioned by the German administration.

Thus the *Prussian State Railway* states that the interested corporations and the public show a tendency to ask for more guarantees.

According to the *Baden State Railway*, the parties interested ask that even when the railway is not legally liable, it should grant compensation in a spirit of conciliation.

The *Saxon State Railway* states that the chambers of commerce ask that the liability of the railways should be increased.

The *Bavarian State Railway* mentions that the commercial world desires the abolition of the restrictions in the liability of railways specified in paragraph 77 of the home regulations.

Finally, although that country is not within the scope of this report, it seems interesting to note that the same tendencies at present are showing themselves in England. The railway companies there generally offer the public two scales of rates for these perishables, the lower being when the goods are carried at owner's risk only.

The difference between these two scales is moreover so great that the lower one is in fact nearly the only one applied.

Now these rates without liability, " owner's risk rates ", have been made the subject of strong complaint before the Commission appointed February 1908 by Parliament.

Finally, the meeting decided to ask for an extension of liability, drawing up a list of well-defined cases in which compensation is to be paid.

Generally speaking, the railways oppose these tendencies, and the fears on which the opposition is based are expressed in the answer to our list of questions, given by the administration of the Italian State Railway :

It is particularly necessary in the case of perishables that liability should be limited and that in tariffs providing for it, the presumption of irresponsibility of the railway should be maintained to compensate for the reduction of rate, taking into consideration not only the

nature of the goods, but also the fact that these may have been consigned in a bad condition, so as not to be able to stand the journey without damage.

As it is not possible to ascertain the state of the goods at consignment, and as it is nearly always not possible, without great difficulty, to ascertain with certainty at arrival, whether the goods when consigned were in good condition or otherwise, it is necessary to uphold, as far as possible, the principle of conveyance at the risk and peril of the consigners, and not to increase, in any case, the liability of the railway.

This way of looking at the matter has as result, that on most of the railways, the French railways excepted, it is very usual to apply to these consignments of perishables carried as quick freight, either simply the slow-freight rates, with their regulation times of conveyance, or the accelerated-slow-freight rates, with times still very long.

No doubt in practice attempts are made to carry the consignments quickly, and we shall see later on what remarkable efforts have been made for the purpose, and what results have been obtained; but in case of any irregularity, the power the railways have of appealing to the " legal time " practically eliminates all their liability.

In France, quite a different line was taken in the tariffs established in 1907 after the meeting of the commission referred to above : while the booking service and the actual carriage were accelerated as much as possible, it was decided to accept, as regards the public, and under certain conditions, liability for proper arrival, that is to say, for the arrival of the perishables at the time at which the trains in fact carrying them are due.

Which system is the better?

From the objective point of view, we have seen that the public incontestably prefers that the railways should be liable; from the subjective point of view of the latter, are not the fears shown everywhere with regard to these liabilities exaggerated, and is not immunity from them purchased at too dear a rate by the excessive reductions of the tariffs?

Statistics of the claims settled by the Paris Orleans station under the French system of liability, during the period 1 July 1908 to 30 June 1909, show that in the case of perishables carried as quick freight during a period of difficult service, the payments in consequence of delay and damage of perishables did not reach 55,000 francs (£2,200), for a traffic of 112,700 tons, for carrying which 7,300,000 francs (£292,000) were paid. This is less than 50 centimes per ton (4·87*d.* per English ton), or 0·75 per cent of the receipts.

This is relatively a very small proportion, and as on the other hand, the statistics and curves given above show, in the case of many French articles, that in spite of the higher rates, there has been at least as much progress as in other countries, must we not conclude from these different results, from the very attitude of the

parties interested, that these material reductions in the rates are not in reality properly counterbalanced by the elimination of the liability?

Reasons for reducing the rates or giving special facilities may however arise in some countries from considerations of another kind, from geographical, latent, as yet ill-defined considerations, but which nevertheless have a considerable influence on the making of the rates.

It is in fact very clear that this traffic of perishables, particularly of seasonable perishables, has a different character in two such countries as France, where there are such varied climates, from the mild winters on the Mediterranean coast to the bleak shores of the North Sea, and Germany, a country with a continental climate, much more uniform and colder.

In France, this diversity of climate and the earliness of the southern seasons have forcibly led to the exchange of produce, whatever so to say the rates might have been; in any case, one was in the presence of already-existing traffic, which in cases was considerable; more reserve was necessary in lowering the rates or else too great sacrifices would have been incurred.

In Germany on the other hand, on account of the relative uniformity of the produce of the whole land, there is no doubt less tendency to such a spontaneous exchange of produce between the different districts; on account of this minor importance of the existing traffic, there is less objection to the reduction of rates; such reduction moreover seems necessary in order to permit such exchanges between districts where the values of the produce differ but little; and it also seems necessary in the case of perishables necessarily purchased in other countries, which when they arrive at the frontier have already had to pay carriage thither, so as to facilitate their entry and their distribution inside the country.

This explanation which is so evident is not a simple work of imagination, for it is a remarkable fact that it is confirmed by the facts observed in the working of the different railway systems of one and the same country.

Thus for instance, in France, the Eastern and the Western Companies, whose systems extend throughout at about the same latitude, with little differences between the climates of the districts through which they run, have been able to make, for perishables generally, rates which neither the Paris-Lyons-Mediterranean nor the Orleans Companies, with their systems extending north and south with much greater diversity of climate, could look at.

Taking still another point of view, this diversity of produce exists in reality only during a rather short period of time, when on account of the earlier season of the south, its produce ranks as early fruit and early vegetables; it ceases when the production becomes more extended and then general; now for some time the Paris-Lyons-Mediterranean and the Orleans Companies have been showing a tendency to

lower their rates at the times, varying for the different kinds of produce, when they lose their early character, and this gives us an indirect proof, we may perhaps say an instinctive one, that it is this diversity in the seasonal periods which is really the true cause that the rates on the chief French railway systems are comparatively high.

Having explained the general notions which explicitly or latently influence the making of the rates for carrying perishables, we shall now consider in detail the tariffs applied in the different countries, or at least in the more important countries, in order to obtain a general grasp of the different principles on which the making of these tariffs is based.

In this investigation we shall follow the order adopted in the statistics, and consider separately, firstly the chief importing countries and then those who principally supply those imports.

GERMANY.

Germany comes first in this detailed investigation; owing to the very great importance of its traffic, its rating principles require a somewhat extended examination which is moreover facilitated by the very full information supplied by its different railway administrations.

Home tariffs. — As a general rule, the tariffs of the different State railways divide perishables *sent by quick freight* into two different classes :

1° Perishables which under a special tariff (" für bestimmte Eilgüter ") *pay slow-freight rates :* milk, butter, fish (except oysters and lobsters), some vegetables (gherkins, salads, broad beans, French beans, spinach), fruit (except so-called southern fruit);

2° *The remaining perishables pay quick-freight rates;* eggs, cheese, dead poultry, meat, oysters and lobsters, fresh flowers, vegetables not named in the special tariff, potatoes, colonial vegetables and fruit, game.

As far as one can conjecture, the division of the perishables into two classes seems logically inspired by a double consideration : firstly to charge quick-freight rates on such produce as poultry, meat, shell-fish, flowers, etc., which owing to its value can stand much higher rates; secondly by means of this higher rate to keep out of the quick-freight trains, which they would unnecessarily encumber, the less delicate perishables such as eggs, oranges, certain vegetables, etc., which can stand the time slow-freight trains take.

The scale of rates for the home traffic on the German railways is given in the following table.

The *quick-freight* rates are calculated at the general-class slow-freight rates on double the real weight.

*

DISTANCES.	Rate per 1,000 kilograms, in francs.								Extra charges (per 1,000 kilograms) in francs, for distances exceeding 40 kilometres.				
	Broken loads.		Truck loads of 5 tons.			Truck loads of 10 tons at slow-freight rate.			Broken loads.		Truck loads.		
				Slow-freight rate.			Certain vegetables listed.						
	Quick-freight rate.	Slow-freight rate.	Quick-freight rate.	General class A1.	Certain vegetables listed (1)(2) A2.	General class B.	(1) Special I.	(2) Special II.	Quick-freight rate.	Slow-freight rate.	Quick-freight rate.	Slow-freight rate, 5 tons (A1).	Slow-freight rate, 5 tons (A2) and 10 tons.
50	13 75	6·90	8·40	4·20	3·15	3·75	2·85	2 20					
100	26·25	13·15	16·80	8·40	6 25	7·50	5·65	4·40					
200	51·25	25·65	33·50	16·75	12·50	15·00	11·25	8 75					
300	73·75	36·90	50·30	25·15	18·75	22·50	16·90	13·15					
400	93·75	46·90	67·00	33 50	25·00	30·00	22·50	17·50	5·00	2·50	5·00	2·50	1 50
500	111·25	55·65	83·80	41·90	31·25	37 50	28 15	21·90					
600	126·25	63·15	100·50	50·25	37·50	45·00	33·75	26·25					
700	141·25	70 65	117·30	58·65	43·75	52·50	39·40	30·65					

(1) Broad beans, French beans, spinach, turnips, cauliflowers, red cabbage.
(2) Gherkins, salads of all kinds.

As regards accelerated quick freight, the general-class slow-freight rates are applied, on four times the real weight both for broken loads as well as for truck loads.

This scale of rates is applied by all the German railways; *the Bavarian State Railway* however extends the benefit of the *slow-freight* tariff to *all* vegetables as quick freight, for instance to asparagus, hops, horse-radish; so that on that system *quick-freight* rates are limited to eggs, cheese, poultry, meat, flowers, game and venison.

The general division of the perishables into two classes has moreover been affected by one important exception, by the temporary alterations of class of meat, the quick-freight consignments of which paid low-freight rates from 1 January 1907 to 31 December 1909.

The motive for this exceptional measure was the serious rise in the cost of meat in Germany. However, in spite of the considerable reduction (50 per cent) in the cost of carriage, there was no appreciable result, according to the majority of the railway administrations. This is a fact to be remembered when we examine, later on, the results which one may hope to attain by reducing the rates.

Apart from this exceptional and temporary provision, the tariffs of the different German State railways grant special reductions for the transport of milk which is usually only carried short distances; this we propose to examine more particularly, comparing the measures taken in this connection by the different administrations and the results obtained.

The German tariffs do not as a rule provide for seasonal conditions; such are not referred to except in the answer sent by the administrations of the Alsace-Lorraine State Railway; this railway carries every year, from 1 August to 15 September, nuts by quick-freight trains at slow-freight rates.

We also have to note a special tariff of *the Bavarian State Railway*, under the terms of which certain perishables, if sent in consignments *not exceeding 25 kilograms* (55 lb.), are sent as *express goods* (" Express Güter "), at broken-load *slow-freight* rates; these perishables are butter, lard, cheese, eggs, poultry, honey, fruit, berries, wild flowers, fresh meat, sucking pigs, lambs and kids.

A similar arrangement on *the Baden State Railway* is limited to the following articles : butter, cheese, eggs, live and dead poultry, honey, fresh vegetables of all kinds, fresh berries, fruit of all kinds except southern, grapes, plants of all kinds, wild flowers.

On the other hand the limit of weight of the consignments is increased from 25 to 50 kilograms (from 55 to 110 lb).

These are instances of agricultural-produce tariffs similar to those applied on English railways; they however possess the postal character, with rates fixed for zones and for given weights, like the Italian tariff and like that at present studied in France, the adoption of which now only depends on reduction of tax.

International tariffs. — Owing more especially to the central situation of Ger-

many and its increasing needs, the international tariffs there are much elaborated on the different railways.

Besides the combined rates with the Italian railways, which are the most important and which we will consider specially later on, we find in the answers of the different administrations mention of a certain number of combined rates of which the following is a summary :

Alsace-Lorraine, *South Germany and Switzerland* have common rates, the slow-freight rates of the different railway systems being combined, *but with guarantee of time explicitly limited to the slow-freight time*. *Alsace-Lorraine and Austria* have combined rates, the slow-freight German rates being combined with the reduced quick-freight rates of the Austro-Hungarian railways.

The *Wurtemberg State* has numerous international tariffs for the import of *eggs*, as slow freight with slow-freight rates; there is also a slow-freight combined tariff with Switzerland, for *cider apples*, but no particulars are given.

The *Baden State* has combined rates from Rotterdam and from Antwerp, in order to make the rates of those parts correspond with those of the German ports by means of equal mileage rates or fixed equal rates. There are also special rates from the Rhine ports to the Swiss frontier, fixed in such a way that combined with Rhine shipping rates they equal the through rates of the ports by other iron roads.

The *Bavarian State* has combined rates with several German railways :

For *eggs* in transit from the Levant, the Bavarian part of the rate being reduced to 4·9 pfennigs per ton-kilometre (0·962*d*. per English ton-mile);

For *live poultry* imported from Russia;

For *sea-fish sent from the North German ports* to the different stations in Bavaria;

For *sea-fish from Belgian and Dutch ports* at rates equal to those in the last case, as far as Gemünden, and supplementary rates beyond of 4 pfennigs per ton-kilometre (0·785*d*. per English ton-mile).

But these different rates do not seem to be based on only general principle, but to be of an occasional character or depending on circumstances.

This is not the case with the Italo-German combined tariff, with or without the use of Swiss and Austrian lines, and it is owing to this general character, to the importance and the variety of the traffic it affects, that it seems worthy of special examination.

The information supplied on the subject of this tariff by different administrations is very varied :

According to the *Prussian State Railway*, it is made by combining the rates of the different administrations and offers above all the advantage of through rates. This administration also mentions the existence of an exceptionally reduced tariff for complete truck-loads of all the perishables except *meat* and flowers (this exclusion of meat is to be noted; it quite corroborates what has already been said about the

impediments generally placed in the way of this traffic in international exchanges).

According to *Alsace-Lorraine* the German share in the quick-traffic transport consists of rates taken from the slow-freight tariffs of that country, but *with guarantee of time exclusively limited to the slow-freight time.*

The *Baden State* affirms that in the case of 10-ton truck-loads, the German railways calculate their share at the uniform rate of 6 pfennigs per ton-kilometre (1·178*d.* per English ton-mile), which moreover is the general-class rate B of the slow-freight tariff.

The *Bavarian State* applies to the fresh fruit of Italy, in transit via the Brenner, to other German countries, the reduced rates applying via the St. Gothard, and for the transport thus effected on its lines it charges the following rates per ton-kilometre :

5-ton truck-loads . . . 4·24 pfennigs (0·832*d.* per English ton-mile).
10-ton — — . . . 3·44 — (0·675*d.* — —).

In order to determine the reductions offered by the Italo-German tariff as compared with the ordinary German rates, it is best to compare these rates with the amounts charged for the German part, in the combined tariff, observing however that the latter tariff is in fact extended to nearly all perishables, while in the home tariff or in the combined tariffs with other countries, a certain number of these perishables do not benefit by the application of slow-freight rates.

TERMINALS.		Distance, in kilometres.	German share of Italo-German tariff, in francs.	Rates for class B (10-ton truck-loads), in francs.	Difference per 1,000 kilograms, in francs.
Munich, Central station	Pino. . .	568	44·20	43·50	+ 0·70
	Chiasso . .	613	47·50	46·90	+ 0·60
	Peri . . .	412	36·00	31·90	+ 4·10
Stuttgart, Central station	Pino. . .	508	38 40	39·10	— 0·70
	Chiasso .	552	41·40	42·30	— 0·90
	Peri. . .	648	52·10	49 50	+ 2·60
Dresden, Altstadt . .	Pino . .	1,023	74·60	77·40	— 2·80
	Chiasso . .	1,068	77·40	80·30	— 2 90
	Peri. . .	922	69·20	69·70	— 0 50
	Pontebba .	927	59·10	70·10	— 11·00
Berlin, Central Market .	Pino. . .	1,127	82·30	84 80	— 2 50
	Chiasso .	1,172	85·10	88·50	— 3·10
	Peri. . .	1,046	78·40	78·80	— 0·40
	Pontebba .	1,123	73·60	84·80	— 11·20

The preceding table in which several instances are given, illustrates the differences which are most frequently to the advantage of the Italo-German tariffs, but which are in some cases even to its disadvantage, no doubt owing to the influence of the rates of the intermediate Swiss or Austrian railway systems; but they are in every case of very little importance, certainly not important enough to exercise an appreciable influence on the development of this special traffic.

The advantages of the Pontebba line are to be noted; they result no doubt from concessions made by the Bavarian State Railway to compensate for the natural increase of the Italian rates for the distant point of transit and thus compete with the rates by the other routes.

SWITZERLAND.

a) Federal Railway.

Home tariff. — Perishables are carried under the conditions of special tariff No. 3 at an accelerated speed; this tariff fixes the following rates :

—	Rate, in francs, per 1,000 kilograms.		
	Broken loads, in francs.	Truck-loads.	
		5,000 kilograms, in francs.	10,000 kilograms, in francs.
Fixed charges	2 00	2·00	2·00
Rate per ton-kilometre up to 700 kilometres. . .	0·25	0 15	0·13

Under the conditions of this tariff the consignments accompanied by quick-freight way-bills are in fact treated like quick-freight consignments; but it is specially stipulated that in case of delay the slow-freight time can alone be claimed.

We may also mention a specially-interesting tariff for transport *under the same conditions as luggage*, with half an hour for delivery, for bread, fresh butter, new-laid eggs, liquid milk and fresh cream.

The rates applied are about 1 franc (9·75*d.* per English ton) less than the rates for broken loads in the tariff alone; but here again it is stipulated that in case of delay the slow-freight times alone can be claimed.

Milk is also carried under the conditions of an interesting subscription tariff which we will consider later on.

Sea-fish benefits by a tariff which seems exceptional; it is carried by ordinary passenger train at slow-freight rates (classes I, A and B), and by *express* train at single quick-freight rates, instead of double quick-freight rates.

International tariffs. — The answer of the Swiss Federal Railway mentions, in a general way and without giving details, the existence of tariffs common to it and to the railways of neighbouring countries.

b) St. Gotthard Railway.

These tariffs are also mentioned in the very summary answer of the St. Gothard Railway which states that there is a very complete system of common tariffs : Swiss-Italian, Belgian-Italian, German-Italian, based on the slow-freight rates; the scales of the rates are those of the Prussian State applied from terminal to terminal on the sum of the German and Swiss distances taken together.

BELGIUM.

Home tariff. — Perishables are carried at the rates of tariff No. 2, known as the accelerated-service tariff, the rates of which are calculated according to the following scale; in spite of its title and the fact that those perishables are carried on parcel trains or passenger trains, it only gives a legal right to the use of goods trains.

	Up to 5 kilometres	9·00 francs per ton.	
From	6 to 75 —	0·20 franc per ton and per kilometre more.	
—	76 to 150 —	0·16	— — — —
—	151 to 200 —	0·12	— — — —
—	201 to 400 —	0·08	— — — —

Plus 1 franc per ton for terminal charges.

International tariffs. — The answer of the Belgian State Railway does not explicitly refer to international tariffs; but we know that there are very important tariffs of this kind for transit traffic, through Antwerp and Ostend, of Italian produce, Austrian produce, etc.

HOLLAND.

a) Dutch State Railway.

Home tariff. — In principle the consigments are charged the quick-freight rates, which are double the slow-freight rates.

International tariff. — A through Franco-Dutch tariff is mentioned for sea-fish.

b) Dutch Railway Company.

Home tariff. — According to the administration of this railway, the very active

competition of river and canal navigation and particularly the progress made in motor boats, compels it to charge very low rates.

The rates applying to the different articles are given below; they are the slow-freight rates. The quick-freight rates are double the slow-freight rates, but actually, chiefly in consequence of the competition just mentioned, butter, eggs, milk, vegetables and fruit are carried as quick freight while only paying slow-freight rates.

DISTANCE	Broken loads (2).	Truck-loads.		
		Milk (1), eggs (1), butter (1), fresh cheese, poultry and small dead animals, fresh meat, sea-fish and other fish, fresh cut flowers, vegetables (1), fruit (1), game.	Vegetables and fruit in truck-loads.	
			5,000 kilograms.	10,000 kilograms.

N. B. — The florin is converted into francs at the rate of 2·08 francs per florin.
(1) Carried as quick freight at slow-freight rates.
(2) Fresh meat not packed is not accepted except in consignments of 1,000 kilograms and charged at quick-freight rates increased by 150 per cent.

INTERNATIONAL TARIFF. — *With Germany* there are common tariffs for *butter*, *fish and shell-fish*, *some listed vegetables*, *milk*, *most of the fruits*, applying simply slow-freight rates to goods carried as quick freight.

In the case of *sea-fish*, a special quick-freight tariff applies the ordinary quick-freight rates to goods carried as *accelerated* quick freight.

With Belgium there are special slow-freight rates which apply to butter carried (no doubt as quick freight) from several Dutch stations to Liège and Antwerp.

JAVA DUTCH STATE RAILWAY.

This country and this railway do not take any appreciable share in the international movement of the perishable traffic.

Among the information supplied by this administration we may mention an original reduced tariff for conveying ducks in droves from one rice-plantation to another, after the harvesting; this tariff has given excellent results, the number having increased in one year from 40,000 or 50,000 to 130,000; this is an interest-

ing instance of the happy results which may be attained by adjusting the tariffs to the varying needs of local traffic.

EGYPTIAN STATE RAILWAY.

These articles are carried at the rates of a general quick-freight traffic. Exceptionally slow-freight rates are applied to fish carried on passenger trains; this once more shows the generally-recognized necessity of facilitating trade in that special article of food by reducing the rates for carriage.

NORWAY.

The greater number of perishables, when in *broken loads*, are carried as quick freight at the rates of the quick-freight truck-load tariff, or at the rates of the first series of the slow-freight tariff, uniformly increased by 40 ores.

The rates are charged moreover on a minimum weight equal to the number of packages consigned multiplied by 30 kilograms.

Here again we find the practice of a special liberal treatment for fish (except salmon) carried as quick freight; this pays slow-freight rates. When this fish is carried on fast trains, these rates are increased by 50 per cent.

We may note a regulation specifying a special increase of 25 per cent if the *night* train from Drontheim to Christiana is used.

RUSSIA.

Home tariffs. — The ample information supplied by the Vistula and especially by the South Eastern lines shows that the Russian railway tariffs seem simple as far as quick freight is concerned.

According to this information, both the slow-freight and quick-freight tariffs applied on the different railways conform to general regulations in force on all the Russian railways.

Notes added at the end of the tables of the different scales applicable to slow-freight traffic state, in a general manner, that *quick-freight* traffic is charged at the rates of the second class of the slow-freight tariffs; these rates are as follows :

1/12 kopeck per pood and per verst up to 400 versts or 0·127 franc per ton and per kilometre.												
1/15	—	—	—	—	more from	401 to	900	versts	or	0·102	franc	per ton and per kilometre more
1/18	—	—	—	—	—	901 to	1,800	—		0·085	—	
1/24	—	—	—	—	—	1,801 to	2,300	—		0·064	—	
1/36	—	—	—	—	—	2,301 to	4,688	—		0·042	—	
1/25	—	—	—	—	—	above	4,688	—		0·066	—	

As an exception, milk is carried as *quick-freight* at the rates of a scale No. 6 of the slow-freight rates. This scale is :

1/42 kopeck per pood and per verst up to 220 versts or 0·127 franc per ton and per kilometre											
1/53	—	—	—	—	more from	221 to 600	versts	or	0·046	franc	per ton and per kilometre more.
1/47	—	—	—	—	—	601 to 1,527	—		0·032	—	
1/56	—	—	—	—	—	1,528 to 1,600	—		0·042	—	
1/40	—	—	—	—	—	1,601 to 2,000	—		0·038	—	
1/42	—	—	—	—	—	2,001 to 3,190	—		0·036	—	
1/68	—	—	—	—	—	3,191 to 4,723	—		0·022	—	
1/42	—	—	—	—	—	above 4,723	—		0·036	—	

As another exception, fruit and vegetables are carried as quick-freight at the still lower rates of scale No. 7 which for fruit in particular is the same as that of the *slow-freight* tariff. This scale No. 7 is :

3rd class slow-freight	1/45 kopeck per pood and per verst up to 200 versts or 0·102 franc per ton and per kilometre.										
	1/48	—	—	—	—	more from	201 to 400	versts	or	0·085	franc
	1/49	—	—	—	—	—	401 to 630	—		0 08	—
Then	1/28	—	—	—	—	—	631 to 1,260	—		0·057	—
	1/70	—	—	—	—	—	1,261 to 2,843	—		0·022	—
5th class slow-freight	1/42	—	—	—	—	—	2,844 to 3,190	—		0·036	—
	1/68	—	—	—	—	—	3,191 to 4,723	—		0·022	—
	1/42	—	—	—	—	—	obove 4,723	—		0·036	—

per ton and per kilometre more.

The conversion of these rates into francs per ton and per kilometre has been effected by taking :

1 pood = 16·38 kilograms or 61 poods = 1,000 kilograms (2,205 lb.);
1 verst = 1·067 kilometres (0·663 mile);
1 rouble (gold) = 2.67 francs (2*s.* 1·63*d.*);
1 kopeck = 0·01 rouble = 2·67 centimes (0·256*d.*).

Although the notes added at the end of the tables only mention the application of these second-class rates to quick-freight broken loads only, it seems to include the larger number of perishables by truck-loads, as in the case of sea-fish the tables on the contrary explicitly mention the more favourable conditions granted in this case if by truck-load. In these cases, special scale No. 5 is applied, which is as follows :

Up to 615 versts, the above second-class broken-load rate. Beyond this :

1/35 kopeck per pood and per verst from 616 to 1,060 versts or 0·044 fr. per ton and per kilom.											
1/60	—	—	—	—	more from	1,061 to 1,200	versts	or	0·025	franc	per ton and per kilometre more.
1/80	—	—	—	—	—	1,201 to 2,984	—		0·019	—	
1/42	—	—	—	—	—	2,985 to 3,190	—		0.036	—	
1/68	—	—	—	—	—	3,191 to 4,723	—		0·022	—	
1/42	—	—	—	—	—	above 4,723	—		0·036	—	

5th class slow-freight

These scales of the Russian railways give rise to the following remarks :

The first is that the limits of the distances for given rates do not advance regularly, say by hundreds of versts, as on most European railways; these very irregular advances are made no doubt at points most advantageous for reaching important destinations or perhaps for managing existing traffic.

We may also mention the considerable diminution, at greater distances, in the scale of rates applying to fruit and vegetables and to sea-fish in truck-loads.

Finally, we note that the Russian engineers do not tie themselves down to the generally-observed rule of decreasing unit rates with increasing distances; for the unit rates are often raised, either to correspond with the existing scale of another class of tariff, or at the end in order to finish the tariff by a unit rate corresponding to the kilometer rate which the scale gives for the distance at which that last unit rate starts.

In addition to these rates, which are stated by the administrations of the Vistula and the South Eastern lines to apply to all the Russian lines, the latter administration mentions a special tariff applying to the carriage of daily produce on passenger and mixed trains in lots of 10 Russian pounds (9·02 English pounds) and which give, for instance, rates beginning at $^1/_{30}$ kopeck per consignment and per verst (0·0137*d*. per mile) for butter, and at $^1/_{80}$ kopeck (0·0052*d*. per mile) for milk.

Of the other administrations who have answered our list of questions, that of the *Moscow-Koursk* line states that it carries as quick freight, at slow-freight rates, the following perishables : eggs, butter, cheese, dead and live poultry and small animals.

The same system is applied to all other produce *when it is going to be exported*.

The *Transcaucasian* applies scales with unit rates the same as those given for the two first lines, the Vistula and the South Eastern, but decreasing with every zone of 25 versts (16·5 miles).

International tariffs. — The information supplied by the Russian lines mention the existence of international tariffs but without giving particulars. It is only mentioned by the Moscow-Koursk lines, as stated above, that the slow-freight tariffs are applied to quick-freight consignments going abroad.

We find however in the report of the St. Petersburg exchange committee of the first International Refrigeration Congress held October 1908 at Paris, the statement that the export of dead poultry to Western Europe would in the first place be hindered by the absence of any refrigerator-van service (this we will refer to later on), but also by the fact that in Russia the benefit of the reduced international tariffs would, on each line, be limited to three of four stations only; it would no doubt be useful to draw the attention of Russian railways to this point.

SIBERIA.

As Siberia is continually taking a greater and a greater share in the international commerce in perishables, particularly in butter, it would be very interesting to examine the rates in force on the Siberian railway system for this export traffic.

The answers made to the list of questions mention the existence of international tariffs for this traffics, more especially of common tariffs, with the internationa maritime union of the north; but they refer for details to Nos. 1940 and 1914 of the Official tariff bulletin, which were not supplied and which are not in our possession.

It is however possible to supplement this gap from the information supplied by the Russian committee to the International Refrigeration Congress.

It may be concluded that generally speaking the rates on the Siberian system are the same as those given above for the Vistula and South Eastern lines, and that the *slow-freight* tariffs are applied to the *quick-freight* export consignments.

In this way exported butter would have to pay to the ports and to the frontier the rates of scale No. 6 given above, and eggs by truck-load the rates of scale No. 14, which is as follows :

5th class	1/24	kopeck per pood and per verst up to 200 versts or 0·064 franc per ton and per kilometre.										
	1/28	—	—	—	—	more from	201 to	400	versts or	0·057	franc	per ton and per kilometre more.
	1/30	—	—	—	—	—	401 to	900	—	0·051	—	
	1/36	—	—	—	—	—	901 to	1,507	—	0·042	—	
	1/75	—	—	—	—	—	1,508 to	2,944	—	0·020	—	
6th class	1/50	—	—	—	—	—	2,945 to	4,175	—	0·031	—	
	1/45	—	—	—	—	—	above	4,175	—	0·034	—	

In the same note submitted by the Russian committee to the International Refrigeration Congress we find the following instances of export rates for butter, which show that the rates in the scale given above are still subject to further reduction, in accordance with a northern export tariff for beyond the seas.

From Omsk to the following ports.	Distance in kilometres.	Rate per 1,000 kilograms, in francs.		
		Special tariff No. 6 (1).	Northern export tariff for beyond the seas.	Proposed.
St. Petersburg.	3,524	112	106	122
Reval	3,829	115	108	126
Riga.	3,792	118	108	128
Windau.	3,960	119	111	130
Libau	3,983	119	111	131

(1) The rates given in this table are actually copied from the note of the Russian Committee, but it

These are very reduced rates; but the same source of information states that the administration of the railway is proposing to raise them to the figure given in the last column of the preceding table.

During summer, a very small extra rate of 1 kopeck per pood, or of 61 kopecks, or 1*s.* 3·90*d.* par English ton is charged for the use of the refrigerator vans necessary.

The note does not mention the rate for eggs; with reservation of the possible extension to this commodity of the special northern export tariff, we find that by the pure and simple application of slow-freight scale No. 14 to a distance of 3,750 versts, say about 2,486 miles, we obtain a rate of 84·28 kopecks per pood, or of 51·41 roubles per ton (£5.11*s.* 6·84*d.* per English ton).

AUSTRIA-HUNGARY.

The Austrian Railways have only given very summary information about their tariffs; the only special feature shown is that the Austrian State Railway reduces its slow-freight and quick-freight rates by 10 or 15 per cent in the case of 5 and 10-ton truck-loads for export.

As in Germany, the dearness of meat has led to the establishment of a provisional reduced tariff; this tariff which came into force 1 January 1907 did not give any appreciable result, just as in Germany; it was therefore very quickly withdrawn, at the end of March 1907.

The *Hungarian State Railway* applies, by means of a much-used formula, its slow-freight rates to quick-freight exports of butter, fresh berries, French beans, green peas, salads, fresh fruit, spinach, gherkins, fish.

It applies the reduced quick-freight rates to the other perishables exported : poultry, game, fresh meat.

We now see appear, for the first time in this analysis of the tariffs applied in the different countries, a subscription tariff granting subject to certain conditions reductions of 8 per cent in the quick-freight rates, of 20 per cent in the slow-freight rates, to customers who send at least 500 tons of the former traffic, 20,000 tons of the latter traffic, per year.

The administration of the Hungarian State Railway chiefly attributes the growth of this export traffic to this tariff which certainly seems calculated to stimulate the zeal of export merchants.

Another original tariff of this railway system reduçes by 10 per cent, all quick-freight and slow-freight rates for consigments to the central markets of Budapest

---

is to be noted that if we take a rouble gold to be equal to 2·67 francs (2*s.* 1·63*d.*), the application of scale No. 6, for instance, to the 2,460 miles (3,711 versts) of distance from Omsk to Windau would give a rate of 97·57 kopecks per pood, or of 59·52 roubles per ton (68 pood), corresponding to 158·90 francs per ton (£6.9*s.* 1·92*d.* per English ton) instead of the 119 francs (£4.16*s.* 8·73*d.* per English ton) given in the table.

which are to be unloaded and sold by the official intermediate agents. It is however mentioned, that although the traffic has grown, it has not been observed that the prices of articles of food have been favourably affected, as was likely expected when this arrangement was made.

SPAIN.

Two companies have sent answers to our list of questions: the *Andalusian Railway* and the *Spanish Northern Railway*.

The *Andalusian Railway*, in the case of home freight traffic, applies to vegetables and fruit kilometer rates varying from 0·2213 to 0·2 peseta per ton (from 3·4738 to 3·1394*d.* per English ton-mile) (1); sea-fish is here again specially favoured, the lower limit of the rate being reduced to 0·1685 peseta (2·6450*d.*)

In the case of international traffic, fruit and vegetables which are exported pay quick-freight kilometre rates varying from 0·2518 to 0·2073 peseta per ton (3·9526 to 3·2541*d.* per English ton-mile). In the case of fruit imported from the Canaries, there is a common tariff, in combination with the Spanish Transatlantic Company and the Madrid-Saragossa-Alicante Railway; this reduces the limits to 0·1379 and 0·1269 peseta (2·1647*d.* and 1·9920*d.* per English ton-mile).

The *Spanish Northern Railway*, in the case of home quick-freight traffic, applies to perishables a special tariff with kilometre rates varying from 0·42 peseta (6·5929*d.* per English ton-mile) at 50 kilometres (31 miles) to 0·209 peseta (3·2807*d.* per English ton-mile) at 1,338 kilometres (831 miles).

The fixed rates applying to certain definite runs are based on kilometre rates which are within the following limits:

Live poultry	0·27 to 0·28 peseta	(4·2383*d.* to 4·3953*d.* per English ton-mile).
Dead —	0·28 peseta	(4·3953*d.* per English ton-mile).
Oysters	0·12 to 0·18 peseta	(1 8837*d.* to 2·8255*d.* per English ton-mile).
Fish	0·38 to 0·40 —	(5·9650*d.* to 6·2789*d.* — —).
Vegetables and fruit	0·22 to 0·23 —	(3·4534*d.* to 3·6104*d.* — —).

As regards international traffic, there are the following rates for sea-fish from Portugal:

To Madrid	0·41 peseta	(6·4359*d.* per English ton-mile).
To Saragossa	0·23 —	(3·6104*d.* — —).

For exports of fruit and vegetables to France, and for imports of produce from the Canaries, the conditions are very much the same as those mentioned in the case of the Andalusian Railway.

Finally the Spanish Northern joins in a common French-Spanish-Portuguese tariff; the kilometre rate on the Spanish section varies between 0·236 and

(1) Nominally the peseta has the same value as the franc; according to the present rate of exchange: 1 peseta = 0·91 franc, approximately.

0·225 peseta (between 3·7046*d.* and 3·5319*d.* per English ton-mile), and it moreover gives absolutely no result as far as the perishables traffic is concerned.

ITALY.

Italy is one of the countries where most attention has been devoted to the perishables traffic; we have already seen that it is even considered to have a character of national interest. The tariffs there are very complete and the answer sent by the administration of the Italian State Railway in answer to our list of questions and the documents sent with it, give very full information on the subject.

Home traffic. — The essential tool of this traffic in the *accelerated slow freight* tariff No. 50 which applies uniformly to all perishables in *truck-loads*.

The essential principles of this tariff, also the principle of the special export accelerated slow-freight tariff No. 55, is that it gives kilometre rates for 8-ton truck-loads (10-ton in tariff No. 55), subject to the condition that in the case of certain named goods, for instance oranges and lemons, fresh fruit and vegetables, the truck-load rates are applied to the whole load up to 8 tons; while in other cases, for instances butter, meat, fish, poultry, the truck-load rates are only applied to loads up to 4 tons; any weights over and above 4 tons are charged supplementary rates per ton, specified in the tariffs.

Further on, we shall give the rates of this tariff together with those of the similar tariff applied to exports.

In this tariff, we again find an instance (the first was in the *Hungarian State* tariff) of a subscription clause under which special rebates increasing from 0·5 to 5 per cent are given to customers who send from 100 to 1,000 truck-loads per year.

According to the information supplied by the administration of the Italian State Railway, this clause benefited in 1908 twelve customers as follows :

6	to the extent of	0 5	per cent.	1	to the extent of	2·5	per cent.
2	—	— 1 5	—	1	—	— 3	—
1	—	—. 2	—	1.	—	— 5	—

This is a rather small utilization of a clause which is however very logical from the business point of view.

The analysis of the special conditions of this tariff shows the following features :

1° The consignments are sent carriage paid ;

2° The acceleration of the traffic is determined by paragraph 6 of the tariff which runs as follows :

The time allowed for the delivery of the goods at destination is calculated at the rate of twenty four hours for each 225 kilometres (140 miles) of distance plus eighteen hours service operations and six hours for each passage from one railway system to another... The time allowed begins at the time the first train starts (through trains and those not carrying quick-freight goods excepted) after the full truck has been booked, providing that this booking has been effected at least an hour before that train starts.

3° The consignments by this tariff are carried at the risk of the consignor who can claim no compensation from the administration for deterioration, danger, natural waste of the goods, unless it is proved that this arises from the negligence of the administration.

The accelerated slow-freight tariff No. 901, which forms a sort of appendix to this slow-freight tariff No. 50, drawn up in a similar way, includes special reductions for consignments sent from the *southern* provinces to all the stations of the Italian State Railway system.

Besides these tariffs which apply exclusively to consignments consisting of truck-loads, there is for broken loads quick-freight tariff No. 3 which contains two scales of rates, one for consignments of 20 to 500 kilograms (44 to 1,100 lb.), the other for consignments over 500 kilograms (1,100 lb.). A table below give these rates.

This tariff contains one special clause analogous to one we will find in the export slow-freight tariff No. 55, according to which consignements of less than 500 kilograms (1,100 lb.) of certain named articles, sent in packages not exceeding 50 kilograms (110 lb.) in weight, can by agreement with the railway be carried the whole or part of the way by *through or accelerated* trains subject to the condition that 50 per cent more is paid for the use of *through* trains, and 25 per cent more for that of *accelerated* trains. The other goods named can under the same condition benefit by the use of *accelerated* trains only.

Finally this whole system of tariffs is supplemented by a tariff for small packages of agricultural produce, which contains the following rates, to be paid at the start :

DISTANCE.	Cost per package.			
	Up to 3 kilograms	From 5 to 10 kilograms	From 10 to 15 kilograms.	From 15 to 20 kilograms.
Up to 200 kilometres	0·45 fr.	0·55 fr.	0·70 fr.	0·90 fr.
From 201 to 400 kilometres . . .	0·55 —	0·70 —	0·90 —	1·15 —
Beyond 400 kilometres	0·90 —	1·15 —	1·65 —	2·00 —

Including delivery at address in all places where the cartage rate does not exceed 0·15 franc (1 $^1/_2$*d.*) per package.

International tariffs. — Just like the accelerated slow-freight tariff No. 50 in the case of home traffic, the accelerated slow-freight tariff No. 55, for truck-loads is the essential tool of the export traffic in Italian perishables. Thus it is this tariff which determines the international tariffs.

It is drawn up in the same form as accelerated slow-freight tariff No. 50.

The rates are for truck-loads of 10 tons, but whereas in the case of certain goods, such as oranges and lemons, fresh fruit and vegetables, the rates are applied to truck-loads of 10 tons; in other cases, such as butter, fresh meats, fats, milk, fish, poultry, raisins, etc., the rates are only applied to loads of 5 tons; any weight over and above this is charged supplementary rates per ton, fixed in the tariff.

Eggs in boxes or in baskets, and *live poultry*, benefit in addition by a special reduction of 8 per cent.

The conditions of its application are similar to those of slow-freight tariff No. 50.

We have to note the facilities given for paying the charges by means of cheques drawn on a bank acccepted by the forwarding railway.

The times allowed are those fixed by the Berne International Convention for *slow-freight* consignments with the reservation however that in calculating those times the Italian distances are reduced by 30 per cent; and this results in the following formula :

Time for service operations	2 days.
Time for conveyance, for indivisible fractions :	
In other countries, of 250 kilometres (155 miles)	2 days.
In Italy, of $\frac{250}{0{\cdot}7}$ = 357 kilometres (222 miles)	2 days.

There is the same clause of non-liability, in case of damage unless negligence on the part of the railway is proved.

On the other hand, we find here the same clause as in quick-freight tariff No. 3, referring to possible agreements between the consignors and the administration for carrying the consignments on certain through or accelerated trains.

It is a question of passenger trains other than the special perishables trains and in spite of the very careful and complete organization of the latter, the administration of the Italian State Railway still estimates at 1 per cent that part of the traffic of truck-loads of perishables which has profited by this option.

Finally, one condition favourable to this special trade authorizes the formation of full truck-loads by means of different consignments loaded during the journey, but subject to the condition of paying the rate for the full load from the point of start to that of delivery.

This slow-freight tarif No. 55 also formerly included, like slow-freight tariff No. 50 a subscription clause favouring large customers by rebates which varied, according to distance and amount of traffic, between 5 and 32 per cent of the rates. A recent reduction in the tariff has extended the benefit of these reductions to all customers.

Finally as regards the rates themselves, the Italian system is shown in the following table in which, in order to take the ordinary conditions of practice into account, we have assumed as a general thing that the actual weights carried are :

6 tons in home traffic, for a nominal truck-load of 8 tons;
8 — export — — — of 10 —

DISTANCE.	Rate per ton.						
	Quick-freight tariff.		Accelerated slow-freight tariff.				
			Home traffic No. 50.		Export traffic No. 55.		
	Consignments of up to 500 kilograms, in francs.	Consignments exceeding 500 kilograms, in francs.	Articles not marked with a star, in francs.	Articles not marked with a star, in francs.	Articles not marked with a star, in francs.	Eggs and live poultry.	Articles not marked with a star, in francs.
100	25·52	23·20	12 36	10·30	9·96	9 16	8 07
200	48·72	41·76	22·31	18·88	13·39	12·32	10·07
300	67·21	59 16	31·27	26·61	18·67	17·18	15·19
400	85·84	76·56	39·31	33·47	23·43	21·56	19·05
500	102 08	91 64	46·17	39·48	27·42	25 23	22·40
600	118.32	106·72	52·18	44·63	31·03	28·65	25·36
700	132 24	120·64	57·67	49·44	34·25	31·51	28·07
800	146·16	134·56	62 82	53·90	37 25	34·27	30·64
900	157·76	146·16	67·97	58·37	40·12	36·91	33 09
1,000	169·36	157·76	72·95	62·66	42·00	38·64	34·65

These rates are very reduced and the importance of the concessions so made by the Italian railways, particularly as regards exports, is shown in the following instances taken from the report of the general administration of the Italian State Railway to the International Refrigeration Congress.

Fresh grapes.

DESTINATION STATION.	Frontier stations.	Journey.	Starting from Naples.		
			Distance, in kilometres.	Rate per truck, in francs.	Rate per truck-kilometre, in francs.
Berlin-Anh. Dresden	Peri.	Italy	849	345·40	0·406
		Other countries	1,028	771·00	0·751

Thus the Italian railways make real and very great sacrifices on behalf of this perishables traffic. We shall consider, at the end of this chapter, how much these sacrifices have contributed to the final result and how much in general reductions in the tariffs can *a priori* influence this special traffic.

FRANCE.

Home tariffs. — In the general considerations which we discussed at the beginning of this chapter, we mentioned the particular position of France as regards traffic in seasonal articles, on account of the different climates in different districts, differences much greater than, for instance, in Germany with its continental climate, in Italy which everywhere has a Mediterranean climate; we hence concluded *a priori* that logically the French rates should be higher, at least during the early-vegetables period. Extending this idea, we drew attention to the fact that the different French railway systems could be distinguished according to their geographical orientation in latitude (Eastern, Western, Midi) or in longitude (Paris-Lyons-Mediterranean, Orleans), and that it logically followed from their situation that the former should, at least as far as seasonal traffic is concerned, have lower rates than the latter.

Now although probably this kind of geographical law was not realized from the beginning, yet it has been followed instinctively and experience has fully

confirmed it. In the case of fruit and vegetables, the tariffs of the first three railways contain much more favourable conditions, as is shown in the following table :

1. *Fruits.*

DISTANCE.	Eastern, towards Paris.	Midi, accelerated slow-freight.	Paris-Lyons-Mediterranean.		Orléans.	
			Truck-loads.	Truck-loads of 5 tons.	Truck-loads.	Truck-loads of 5 tons.
Kilometres.	Francs.	Francs.	Francs.	Francs.	Francs.	Francs.
100	19·50	24	24	24	24	24
300	47·50	48	69	69	69	69
500	75·50	80	111	96	96	90
700	...	112	130	115	115	109

2. *Vegetables.*

DISTANCE.	Western accelerated slow-freight.	Paris-Lyons-Mediterranean.			Orléans.			
		Truck-loads.	Truck-loads of 5 tons.	Periodical tariff.	Truck-loads.	Truck-loads of 5 tons.	Periodical tariff.	Periodical tariff truck-loads of 5 tons.
Kilometres.	Francs.	Francs.	Francs.	Francs.	Francs.	Francs.	Francs.	Francs.
100	16	16·50	16·50	...	16	15	11·20	10·50
300	44	48·00	48·00	47	48	44	33·60	30·80
500	52	76·00	76·00	67	80	72	56·00	50·40
700	57	101·00	90·00	80	102	90	71·40	63 00

In the second table, we give for the Paris-Lyons-Mediterranean and the Orleans railways the rates resulting from the seasonal tariffs, that is to say, from the reductions made at the end of the special early-vegetables period, when production has become more general, and needs can be satisfied on the spot, and when the selling prices accordingly become more uniform and no longer show differences greater than the cost of carriage, which previously had made it profitable to send the articles from one place to another.

We may at once state that the results of this tariff have been satisfactory on the

Orleans system at least, as far as we can judge by the comparison of years when there were great differences in the climatic conditions, that is to say when some seasons were early and some were late, when sometimes there were very rich harvests and sometimes the reverse.

For instance, this seasonal tariff was started in 1905 as regards green peas; now if we complete the results obtained since 1899 in the years when the season started after May 1, that is to say, if we leave out the other years when conditions were more abnormal, we obtain for the traffic to Paris the following table of the results obtained :

YEAR.	Season.		Tonnage.			
	Beginning.	End.	Total.	Before 1 June.	After 1 June.	Per cent.
			Tons.	Tons.	Tons.	Tons.
1900	5 May.	19 June.	4,631	4,055	576	12
1901	8 —	25 —	2,732	1,589	1,143	42
1904	3 —	23 —	5,551	4,530	1,021	18
The seasonal tariff came into force 5 June 1905; the season was already very advanced.						
1905	1 May.	22 June.	5,484	3,375	2,109	38
1906	10 —	22 —	3,428	1,545	1,883	55
1907	14 —	20 —	4,634	1,995	2,639	57
The differences are still more characteristic if we consider the special consignments sent from the southern sections of the system.						
1900	5 May.	19 June.	3,630	3,481	149	4
1901	8 —	25 —	1,162	977	185	16
1904	3 —	23 —	2,908	2,808	100	3
See the remark above.						
1905	1 May.	22 June.	2,828	2,420	408	14
1906	10 —	22 —	1,634	1,030	604	37
1907	14 —	20 —	2,561	1,654	907	35

Allowing always for the variations in the yields of the different years, it certainly seems that the results definitely justify the formula to which logic had led.

After the discussions of the extra-parliamentary commission already mentioned, the French administrations were led to readjust the tariffs applied to the perishables traffic, and except as regards some differences of detail on certain railways,

particularly as regards seasonal reductions, they finally arrived at the following formula :

NAME OF MERCHANDISE.	Scale applicable per consignment of at least 50 kilograms or paying for that weight.	Scale applicable per truck-load of at least 5,000 kilograms [1] or paying for that weight.
§ 1. — Live animals, in cages or baskets, of the following descriptions : lambs, quails, kids, guinea pigs, sucking pigs (not weighing more than 30 kilograms each, package included), snails, rabbits, pigeons, tortoises, poultry, butter, cheese, fats (margarine, lard, fresh suet), milk, yeast, eggs	A.	B.
Fruits other than grapes [2]		
Dead game, meat, dead poultry		
§ 2. — Grapes.	B.	C.
§ 3. — Mushrooms, gherkins, vegetables, melons.	D.	E.
§ 4. — Shell-fish, lobsters and crabs, oysters, mussels, fresh fish .	E. [3]	

[1] When the load in the wagons exceeds the minimum weight of 5,000 kilograms, the rates of scales B, C and E are reduced by one tenth for the excess weight.
[2] The scales B and C apply to all fruit, carried from any one station to any other station on the State, Northern, Orleans and Western systems, subject to the condition that at least two of these systems are concerned.
[3] To Paris only as far as consignments from the Midi system are concerned.

—		Scales. A.	B.	C.	D.	E.
		Francs.	Francs.	Francs.	Francs.	Francs.
Up to 100 kilometres, per kilometre . .		0·24	0·24	0 24	0·24	0·24

1,000 —	145 00	136 00	130·00	120·00	105 00

This French tariff differs from the tariffs of other countries, especially from the German and the Italian tariffs, by the classification of the goods into a larger number of separate classes, not only in the case of truck-loads, but also in that of broken loads. This division is in agreement with the ordinary principles of tariff-making in France, and has more especially the object of limiting the application of reduced rates to the articles only which would probably be influenced thereby, and of proportioning the amount of reduction to the presumed needs of those articles.

The knowledge which we have now acquired about the progress of these special transports, shows in fact that although there are traffics such as that of sea-fish, fruit and vegetables, which the railway can influence, there are other cases, such as meat, where reduced rates as a rule only result in sacrifices without any compensating advantages, and the recent negative experiences in Germany and Austria, fully demonstrate this.

This observation must, however, be only taken in a general sense, for particular conditions can, even in the case of these goods, make the reduction of rates advantageous. Such would, for instance, be the case with meat; in this case one might, quite apart from any idea of increasing the consumption, be led to examine the question of reducing the tariff with the sole object of inducing a change in the business by giving a preference to such meat transports as compared with transports of live animals, where there are always difficulties.

As regards the conditions of liability, we gave at the beginning of this chapter

particulars of the difference between the principles adopted in France and those adopted in other countries; in order to make this matter more clear, it seems useful to reproduce those of the conditions under which this new tariff is applied which deal more especially with this liability :

Condition of the goods. — The perishables must be sent in such a condition as to be able to stand an extra period of twelve hours, without deterioration from over-ripeness or staleness.

Rates and times. — The carriage of perishables, for which the consignor has claimed the benefit of the present tariff, is effected by trains specially designated by the administrations, the time-tables of which are brought to the knowledge of the public.

In the absence of any indication of route, the carriage is considered as having been effected by the shortest route and rated accordingly; the time allowed is calculated as by that route.

If the consignor indicates a given route, the rate and the time allowed are calculated as by that route.

The consignor also has the right to limit himself to the demand for the quickest route; in that case, the railway administrations must determine what combinations of trains give the quickest route; the rate and the time allowed are calculated as by that route. But the consignor must have advised the forwarding station, in writing, at least twelve hours before handing in his goods, the night hours not being counted, and informed it at what time he is actually going to hand in the goods.

Exceptionally, as regards certain given relations brought to the knowledge of the public, the railway administration may effect the carriage of goods, of their own accord, by certain trains on other deviated routes, applying the rates for the short route, and calculating the time allowed from the time-tables of those trains.

Perishables, for which the present tariff is claimed, are forwarded by the first train which starts after the time the consignment has been handed in and which runs : *a*) on the short route (or the deviated route if it has been officially indicated; *b*) on the route named by the consignor or on the quick route, if the consignor has asked for this.

The stations are not bound to accept for any given train any consignments handed in less than three hours before the train starts.

The refusal of their acceptance must be recorded by an early entry on the way-bill; in the absence of any such entry, the carriage is considered to have been effected by the first train named, the time of starting of which follows the hour at which the consignment is handed in under the conditions mentioned above.

If any extra trains are run, duplicating, triplicating, etc., the train named, the consignment is always considered as carried by the last of those trains.

When the carriage at a point of exchange between two systems is not effected by one and the same named through train running over both these systems, the extra time allowed for passing, by the trains named, from one system to the other is fixed at : *a*) one hour, if the station is a joint station of the two systems; *b*) three hours when the transfer is between two separate stations of the same locality, with communication by rail; except in the case of Paris, where the time allowed is six hours.

Delays. — In case of a delay of three hours actually prejudicial to the consignors or to the consignees, there is a reduction in the rates charged, under the following conditions :

a) for a delay of three to four hours, one third of the rate can be retained; *b*) for a delay of more than four hours, two thirds of the rate can be retained; *c*) for a delay of more than six hours, the whole of the rate can be retained.

Delays of less than three hours give rise to no reduction. On the other hand, the right of consignors and consignees are reserved in cases in which the delay exceeds twelve hours.

The tariff which has just been reproduced and discussed, and applicable chiefly to commercial traffic, will no doubt be soon supplemented by a tariff for small packages of farm produce, packages for supplying families or small retail firms.

This tariff which now awaits the approval of the higher authorities, has the following form :

DISTANCE.	Weight of package		
	up to 20 kilograms.	from 21 to 30 kilograms.	from 31 to 40 kilograms.
	Francs.	Francs.	Francs.
Up to 100 kilometres. .	1·50	1·50	1·50
from 101 — 150 — .	1·50	1·50	2·00
— 151 — 200 — . .	1·50	2·00	2·50
— 201 — 300 — . . .	2·00	2·75	3·25
— 301 — 400 — . .	2·50	3·50	4·25
— 401 — 600 — . .	3·00	4·25	5·25
— 601 — 900 — . .	3·50	5·00	6·50
above to . . 901 — . .	4·00	5·75	7·50

These small packages of farm produce weighing 10, 20, 30 or 40 kilograms (22, 44, 66 or 88 lb.) or paying for that weight already benefit on the State Railway by a special tariff the rates of which are paid by means of stamps stuck on to the packages by the consignors; as the rates of these tariffs are those of the *general* tariff for perishables, the only advantage is that it is possible to send fractions of the 50 kilograms (110 lb.) which form the minimum weight in the general tariff.

In spite of this advantage, this tariff is utilized but very little.

Seasonal tariffs. — With the same idea of adjusting the tariffs to commercial needs, the French railways and especially the Orleans Railway have during the last few years rather extensively instituted seasonal tariffs for perishables.

The working of these tariffs has been explained above, in the case of vegetables, and the results have been given.

The Orleans Railway has similarly applied, with a certain amount of success, a summer tariff for the carriage of eggs from the south to Paris, eggs which will more actively compete during the hot season with the eggs of the regions further north.

Another summer tariff has made less burdensome for the producers the quick-freight carriage of cheeses, which cannot, on account of the heat, be sent in winter by slow-freight rates.

EXPORT TARIFFS.— The same work of the Extra-parliamentary Commission resulted in an export tariff in which all the French companies join, and which is now the principal tool of such exportation.

We reproduce below that part of this tariff giving the rates, the conditions of application being similar to those of quick-freight tariff No. 114, the chief features of which we have given above.

NAME OF MERCHANDISE.	Scale applicable		Scales applicable to consignments leaving France by a land frontier and going to Belgium, the Grand Duchy of Luxembourg, Alsace-Lorraine, Germany, Switzerland, and to the countries beyond.	
	Per consignment of at least 50 kilograms	per truck-load of at least 5,000 kilograms	per consignment of at least 50 kilograms	per truck-load of at least 5,000 kilograms
	or paying for that weight.			
Live animals (lambs, quails, kids, guinea pigs, sucking pigs, not weighing more than 30 kilograms each, package included), snails, rabbits, pigeons, tortoises, poultry in cages or in baskets, dead game, meat, dead poultry. . .	M	N	...	...
Fruit.	M	N	N	O
Butter, cheese, fats (margarine, lard, fresh suet), milk, yeast, eggs. . . .	N	O	...	...
Mushrooms, gherkins, vegetables, melons	N	O	O	P
Shell-fish, oysters, mussels, crustaceans (crabs, shrimps and prawns, crayfish, lobsters, spring lobsters), fresh fish .	P	...	...	...

N. B. — As regards fruit and vegetables leaving France by a land frontier, there is a reduction of $^1/_{10}$ in the rates of scales O and P for consignments per truck load of at least 5,000 kilograms or paying for that weight, carried in refrigerator vans belonging to private owners or in company's vans equipped at the cost and by the care of the consignor, with racks and removable framing.

When the load in the van exceeds the minimum of 5,000 kilograms, the rates of scales N, O and P are reduced by $^1/_{10}$ for the excess weight.

RATE PER TON.		Scales.			
		M.	N.	O.	P.
		Francs.	Francs.	Francs.	Francs.
Up to 100 kilometres, per kilometre		0·20	0·20	0·20	0·16
For each kilometre beyond	100 up to 200 kilometres	0·18	0·16	0·11	0·11
	200 — 300 —	0·14	0·12	0·11	0·11
	300 — 400 —	0·13	0·12	0·11	0·11
	400 — 500 —	0·13	0·12	0·10	0·10
	500 — 600 —	0·12	0·10	0·09	0·06
	600 — 700 —	0·11	0·10	0·07	0·05
	700 — 800 —	0 09	0·09	0·06	0 05
	800 kilometres	0·05	0·05	0 05	0 05
The scales accordingly give the following rates :					
For 100 kilometres		20·00	20·00	20·00	16·00
— 200 —		38·00	36·00	31·00	27·00
— 300 —		52·00	48·00	42·00	38 00
— 400 —		65·00	60·00	53 00	49·00
— 500 —		78 00	72·00	63 00	59 00
— 600 —		90 00	82·00	72·00	65·00
— 700 —		101·00	92·00	79·00	70 00
— 800 —		110·00	101·00	85·00	75 00
— 900 —		115·00	106 00	90·00	80 00
— 1,000 —		120·00	111·00	95 00	85.00

This tariff has an interesting peculiarity; the rates for exports crossing the frontier by land are lower than those by sea.

Always with the object of limiting sacrifices to what is really useful, it has in fact been thought that considering the general state of the traffic, it was above all advisable to try and reduce the rates to Germany, if not to the level of the Italian export tariffs, at least to reduce the difference as compared with the latter.

We also have to note the reduction of $^1/_{10}$ in the rates in order to encourage the sending of consignments in refrigerator vans or other vans equipped so as better to keep the articles fresh.

Finally, a new proviso authorizes the public to demand the *quickest* route for its consignments, paying naturally the rate of the scale calculated according to the length of that route.

It is not necessary to lay stress on the advantage it is to this perishables traffic to depart from the usual rule of the direct route. It would even be quite desirable to see it introduced into the conventions relating to international traffic subject to the provision, if necessary, of measures of compensation for the direct route deprived of this traffic.

This tariff which applies to joint transport on all the lines also regulates the exports proper of each administration.

We have, however, to mention a very reduced rate of the French Northern Railway for exports of sea-fish to Belgium and the countries beyond, and also the reduced quick-freight and slow-freight tariffs of the Midi Railway to Bordeaux, in order to deflect through that port the consignments to England which otherwise would go from south to north and by the Channel ports.

These Midi tariffs give for instance from Agen to Bordeaux reduced quick-freight and slow-freight rates of 23·05 and 9·90 francs (18*s*. 8·83*d*. and 8*s*. 0·57*d*. per English ton) respectively, while the rate from Agen to Boulogne is 106·90 francs (£4.6*s*. 10·71*d*. per English ton); moreover, the shipping rate from Bordeaux is also very much reduced.

In spite of this enormous advantage only mediocre results are obtained, and the same applies to attempts made by the State Railway to deflect the traffic and attract it to La Pallice, by applying the lowest of their slow-freight tariffs to consignments nevertheless carried on their fastest trains.

These are further proofs that the question of the cost of carriage is far from the most important one for this traffic, but that the conditions of speed and regularity of the conveyance are in reality the essential conditions.

International tariffs.— The export tariff, or an analogous tariff of the Paris-Lyon-Mediterranean, is combined with the Swiss and the German tariffs to form the Paris-Lyons-Mediterranean-German tariff, the through rates of which are obtained by combining the rates of the different countries.

In the case of consignments for Germany, coming from the Western and Orleans systems, those railways and the French Northern Railway had to take into consideration the crossing of Belgium; they have charged themselves with the cost of this crossing and simply extended the rates of their tariffs from the Belgian-German frontier station Welkenraedt to the Belgian-French frontier station Jeumont; this comes to the same thing as reducing their rates to the latter station by the amount

of the Belgian rates : 15·82 francs (12*s.* 10·31*d.* per English ton) for broken loads, 12·53 francs (10*s.* 2·22*d.*) for truck-loads of 5,000 kilograms (11,000 lb.).

Slow-freight rates in combination with the shipping companies and with the English railways facilitate the export to England by the Channel ports, of the eggs from the Bourbonnais and the Auvergne, of the new potatoes from the Paris-Lyons-Mediterranean system and from Algiers, and especially the transit of Italian produce for which those tariffs with very reduced rates equalize the combinations obtained by lines outside of France and going to Ostend and Antwerp.

Reduced quick-freight tariffs, in combination with the shipping companies, facilitate the import into or the transit through France of the perishables from Algiers.

These tariffs are made by simply combining the shipping rates with the rates of the ordinary Paris-Lyons-Mediterranean tariff from Marseilles or Cette; their chief object is to enable the public to send packages direct from Algiers.

Other tariffs in combination with the Spanish railways, deal with the consignments of fruit and vegetables sent from that country to Bayonne, Cette, Bordeaux, Toulouse, Marseilles, Lyons and Paris, or with the consignments of live poultry and seafish sent from France and Catalonia and Valencia. The formers tariffs, which have been in force a very long time, give comparatively high rates of which the following are some examples :

JOURNEY.	Distance.	Vegetables.	Fruit.
Granada to Paris	2,141 kilometres.	420·90 francs.	
Valencia to Paris	1,485 —	314·85 francs.	324·05 francs.
Seville to Bordeaux	1,458 —	293·25 francs.	
Madrid to Paris.	1,452 —	277·45 francs.	
Alicante to Lyons	1,273 —	282·35 francs.	294·85 francs.

We have seen above that the amount of traffic carried under the conditions of this tariff is comparatively very small.

Having now arrived at the end of this examination of the principles adopted in the different countries when making perishables rates, it must be recognized that it fully confirms the existence of the double tendency mentioned at the beginning of this chapter, on the one hand of reducing the rates, the carrier being relieved of all liability, and on the other hand of granting to the public the speed and the guarantees which it demands above all, subject to greater reserve in the reduction of rates.

It is impossible to say *a priori* which of these two points of view is the better; so

many different factors come into play in the variations in this special kind of traffic.

For instance, let us take the case of the Italian railways, which as we have seen, make very considerable sacrifices; can we really believe that the growth of their export traffic is solely due to the reductions in their rates? Is not a great part of it due to other happy circumstances which have arisen simultaneously?

To the considerable development of the needs of Central Europe owing to the growth of its population (Germany has 23 million inhabitants more than in 1870),

To the industrial prosperity and the extension of the general welfare?

To the closer political relations with that country?

To the prolonged neglect of French traders and producers?

To improvements in business and transport methods, etc.?

Can we not also raise as objection to the theory of the superior efficiency of the lowering of rates, the very considerable progress of French exports although the rates for carriage are higher, and that in Germany itself, in spite of the Italian competition favoured by much more advantageous rates for carriage?

The failure of the very reduced tariff applied in Germany and in Austria to meat, in spite of the importance (50 per cent) of the reduction?

The mediocricity of the results of the attempts made to divert to the western ports the fruit going from the south of France to England?

The failure of the reduced Italian tariffs to enable Italy to compete with French fruit on the English market? And so on.

Actually the progress of this particularly-sensitive traffic is not only affected by the conditions which depend on the railways (rates, speed, punctuality, liability, etc.), but also and above all by those which depend on trade and production, quality, selection, condition of the produce; and it is impossible to determine even approximately only the influence of each of these factors.

However, it would not be reasonable to assert that the traffic is not affected by the rates for carriage and that these can be kept at a high level.

Apart from the fact that a prohibitive level would soon be reached, we have seen that judiciously-constructed tariffs have produced good results.

But in such cases, it is a question of limited measures to meet with ascertained wants; were a general reduction to be considered, a recent experience would enable us to measure the importance of the results which could be expected and to see whether these results would sufficiently compensate for the risks run.

From this point of view, we can consider the extensive experience gained on the French railways in 1892, when the tax of 23·2 per cent which was then levied on all quick-freight traffic was repealed. The railways simultaneously reduced their rates, to an extent which, as far as perishables were concerned, amounted on the Orleans Railway to from 30 or 35 per cent, or say by about $^1/_3$ of the former rate.

In the absence of general statistics, the statistics of this railway enable us to compile the following table showing the progress of its perishables traffic both before and after 1892.

Total perishables traffic on the Orleans Railway.

YEAR.	Before 1892.		YEAR.	After 1892.	
	Tonnage.	Receipts, tax included.		Tonnage.	Receipts.
	Tons.	Francs.		Tons.	Francs.
1885	92,400	5,612,000	1893	137,800	6,796,000
1886	97,900	6,215,000	1894	130,200	6,192,000
1887 . . .	99,100	6,355,000	1895	146,600	6,513,000
1888	99,600	6,215,000	1896	163,100	7,126,000
1889	102,400	6,290,000	1897	179,100	8,215,000 (1)
1890	97,400	5,855,000	1898	184,300	8,158,000 (1)
1891	102,400	6,165,000	1899	204,200	9,127,000 (1)

(1) Establishment of the post-office tariff for 10-kilogram parcels.

1892. — Tonnage : 102,300 tons. — Receipts : 5,850,000 francs.

	1885-1891.		1899-1893.		Increase.	
	Tonnage.	Receipts.	Tonnage.	Receipts.	Tonnage.	Receipts.
	Tons.	Francs.	Tons.	Francs.	Tons.	Francs.
Average results of each period	98,700	6,012,000	163,600	7,447,000	64,900	1,435,000
Differences (1)	10,000	553,000	66,400	2,331,000	56,400	1,778,000
Annual average progress in each period	$\frac{10,000}{6} = 1,667$	$\frac{553,000}{6} = 92,200$	$\frac{66,400}{6} = 11,067$	$\frac{2,331,000}{6} = 388,500$	9,400	296,000

(1) Between the results in the extreme years.

The immediate increase in 1893 was evidently not wholly the effect of the new tariff, but was rather due to the fact that certain articles formerly sent as slow freight were now, in consequence of the lowered rates, sent as quick freight; the variations which take place in the annual yield have also to be taken into consideration.

But the much greater and moreover regular progress of the traffic in the second period certainly has to be attributed to the new tariff. This faster progress amounted to an increase of 9,400 tons in the average annual progress, and of 64,900 tons for the whole of the second period.

As compared with a tonnage of about 112,000 tons, which would have resulted in 1899 if the former average increase of 1,667 tons had been kept up, this additional increase of 64,900 tons obtained in six years, marks an increase of about half, and, with all the reservations which such a calculation evidently involves, it seems that we can approximately take this 50 per cent as a measure of the effect of the new tariff.

This is no doubt a very appreciable result; it does, however, seem disproportionate to the considerable effort which a reduction of one third in the tariffs represents, and on the other hand, from the financial point of view, which also must not be neglected, the operation has resulted in no real profit.

The sacrifice made on the basis of the 1891 receipts represented in fact about 1,550,000 to 1,700,000 francs (£62,000 to £68,000); as we can see in the table, this is nearly exactly the gain, 1,778,000 francs (£71,120), which has been realized at the end of six years, by the fact of the more rapid growth of the traffic; with this further reservation that the loss represented *net* receipts while the gain is only in *gross* receipts.

These results are thus really very mediocre and unsatisfactory; although the reductions in the rates were great and could hardly be repeated, they seem to prove definitely that little is to be expected from systematic reductions applied on principle to all the rates.

Actually it is with this special traffic as with any other : reductions in rates are a question of expediency and opportunity; as in the case of all other kinds of traffic, the railway administrations must attentively watch the progress of the different items which make up their perishables traffic, studying the needs with constant attention, so as to intervene when this is necessary, and decide at the right time in accordance with the tendencies which make their intervention necessary.

Apart from the principal questions concerning the rates and the liabilities, there are also some minor points in connexion with perishables traffic, of which it will be useful to give a short summary.

The return of empty packages. — Returned empties are carried on slow-freight trains at exceptionally-reduced rates on most of the railways; some of them even, like the Northern and the State, carry them free of charge.

The amount of the reduction varies; we quote the following instances from the documents annexed to the answers sent by the different administrations :

Germany. — Application of the broken-load tariff, *at half the real weight*.

Switzerland. — Application of the special perishables traffic.

Belgium. — Application of the rates of the first class of the general slow-freight tariff.

France. — Free on the Northern and on the State; on the other lines application of reduced tariffs similar to the following tariff of the Orleans Railway :

For any consignment from 0 to 25 kilograms (from 0 to 55 lb.)	0·25 franc (2 1/2 *d.*).
— — weighing over 25 kilograms (55 lb.) per indivisible fraction of 10 kilograms (22 lb.)	0·10 franc (1 *d.*).

This question of returned empties is a very burning one in England owing to the difficulties which the purchaser has with these packages, in the way of collection, storing, sorting, checking, etc. An active agitation is in progress in favour of packing the goods in *non-returnable packages*, and the railways have been asked to support this agitation by specially favouring the carriage of goods in non-returnable packages.

On the other hand, the middlemen who at present profit by the hire of their baskets, etc., are naturally against these new measures.

This service of returned empty baskets, for carriage on all railways, does not present any greater difficulties than any other goods, for the sorting is effected at the start by the consignors of those empty packages; but it on the other hand gives considerable trouble and difficulty to the seaport stations which receive these empty packages from England; it is quite intelligible that the railways which operate these stations have every desire to get rid of this trouble, particularly if they carry the empties free of charge, like the French Northern Railway.

Finally it may be feared that the trade, with a view to economy, will show a tendency to reduce the weight and strength of the new non-returnable packages as far as possible, to the detriment of the preservation of the goods and to the prejudice of the railway which charges on the gross weight.

Thus the question as it stands is rather complicated. It would no doubt be impracticable to reduce all the old tariffs with an eye to this new state of affairs; but in the case of new tariffs it will likely be possible to examine whether it is advisable to reserve their application to the non-returnable empties, as has been done by the French administrations in their recent export tariff, in the case of goods carried in refrigerator vans or specially-arranged vans and therefore benefiting by a reduction of rate of 10 per cent.

Tariffs between countries having different monetary systems. — Combined tariffs with through rates made by different countries may meet with difficulties either because although the monetary systems are the same the fluctuations in exchange may alter the relative values in some of those countries, or because the monetary systems are different, as in the case of the French-German-Russian tariffs which unite three countries having as their monetary units the franc, the mark and the rouble respectively, and in that of the French-Spanish-Portuguese tariffs whence the corresponding countries have as unit the franc, the peseta, the milreis.

The complications are of two kinds; firstly, with the public from the point of view

*

of the settlement of the charges for the carriage; secondly, as regards the adjustment of accounts between the railways concerned.

1° *The point of view of the public :*

In the case of tariffs with several currencies the most usual practice is to advise the stations concerned periodically of any alterations in the exchange; the amount to be paid is then calculated by converting on this basis the rate or charge of the tariff into the currency of the country where the payment is made.

However different practices also exist :

The Italian-English tariffs consist of fixed prices to London calculated in gold; when there is a premium on gold, as regards Italian paper and money, the railway is authorized to demand the payment in gold of the foreign share of the charges.

The combined French-Spanish tariffs are based on fixed prices given in francs; in order to take the rate of exchange into consideration, it is specified that Spanish consignors must before despatching pay the Peninsular share in pesetas, the French share in francs being collected on arrival. In this way, no adjustment of accounts between the two countries is necessary, as each has received what is due to it; but it is evident that this very simple system which makes it necessary for the consignor to pay out money before his goods are sold, is from the commercial point of view decidedly inferior to the previous one.

This commercial point of view should however not be left out of consideration, and we may assume that it is in order not to give trade the trouble of keeping accounts in two different systems that the German-Italian tariff has been made with the Italian share in lire and the German or Swiss-German share in francs.

2° *The point of view of the adjustment of accounts between the administrations concerned :*

Two systems of adjustment are very usual :

a) By one of the administrations concerned;
b) By a clearing-house kept at joint expense.

a) The first may in certain cases present disadvantages. A rather long interval always elapses between the receipt of the payments for the carriage and the making-up of the accounts. Now in certain countries the exchange fluctuates a good deal. If during that interval the exchange goes up, the administration acting has to pay more than it has received; the contrary is the case if the exchange goes down. Thus it has happened to the Orleans Railway with the French-Spanish-Portuguese tariff, that during a long time the milreis was continually rising till it stood nearly at par; the Orleans Railway which had to purchase from banks the drafts necessary for paying their share to the Portuguese companies as a result suffered successive losses, the total amount being comparatively large. It is true

that the fall in exchange which has occurred since has chanced to compensate it to some extent, but this system nevertheless shows peculiarities which make the clearing-house system preferable.

It is such an international clearing-house established at Brussels, which for instance liquidates all the accounts concerning the joint through traffic of England, France, Holland, Belgium, Germany, Switzerland, Austria-Hungary, Italy. This office sets the debits and the credits of the different administrations against each other, and adjusts the balance sin the most economic way, taking the exchanges into account and reducing the movements of cash to the minimum possible.

One can conceive that if there are any important variations in the exchange, this office will distribute equitably the resulting losses or gains between the administrations concerned.

CHAPTER III.

Carriage. — Trains used. — Acceleration.

Subject to the reserve that most of the administrations, except those in France, do not enter into any real engagement to carry goods in a given time, all at all events try to reduce this time as much as possible.

Passenger trains, parcel trains, special trains during the busy seasons, are all used to carry these perishables as quickly as possible to their destination, without however using the express or fast trains especially reserved for passengers.

Everywhere regulations are issued to regulate the conveyance of these perishables.

The Belgian State and the Italian State, more particularly, have given information on this point of which the following is a summary :

Belgian State. — As regards home traffic, although the tariff does not give a *legal* right to anything except the goods trains, yet *in fact* the home traffic in milk, fresh cheese and butter is carried *on the first and last passenger trains* of the day, during the winter, the spring and the autumn months; on *all* ordinary passenger trains during the warm season, from May to September (both inclusive).

The system of the earliest and latest train is extended the whole year to dead poultry, meat, vegetables, fruit and game.

Eggs, live poultry, fresh flowers, vegetables and colonial fruit are sent by parcels or tranship trains.

Fish is conveyed by all passenger trains.

In the case of international traffic, the system is the same for these different groups, excepting that the articles only conveyed by the earliest and latest train, in the case of home traffic, are in this case conveyed by *all* passenger trains.

Moreover, the use of these passenger trains is, in a general way, prescribed for the stations at which the parcels and tranship trains do not call; the general prescrip-

tion is that the goods should arrive at the exit frontier station *before noon* of the day after the consignment has been handed in at the forwarding station, or in the case of transit goods, at the entrance frontier station.

Italian State. — We have already mentioned the great care taken of this special traffic; this railway has worked out a very complete and very detailed plan for the carriage of this traffic. This plan is based primarily on the running of four chief pick-up trains.

The *Tyrrhenian*, or GG, which runs along the Mediterranean coast;

The *Adriatic*, or PP, which runs along the Adriatic coast up to Bologna;

The *Ionian-Adriatic*, or TT, for lemons and oranges from Sicily;

The *Paduan*, or 5066, for the farm produce of the northern districts.

Other definite trains can eventually be substituted for these chief trains; the trains on secondary lines also act as feeders.

A very clear diagram (reproduced in appendix 3) shows diagrammatically the whole course of this special traffic.

In the other countries, in Germany, Spain, Holland, Austria-Hungary, Russia, France, most of the railway systems have special time-tables for this traffic, some of them very extensive; for instance, that of the *Bavarian State*, which is in nine parts.

In *Siberia*, in the case of butter exported by the Baltic ports, the plan for the conveyance is drawn up in accordance with information supplied by the parties concerned as to their probable shipments.

Nearly over these time-tables are as a rule not issued officially to the public which only receives information, without any guarantee, when it asks for it.

In *France*, this special time-table is sold to the public.

In *Holland*, *Austria-Hungary*, *Russia*, the publication is effected by posters, at least as far as certain services are concerned. It is to be noted that the posters of the *Dutch Railway Company* announce in large letters that these time-tables are not guaranteed; this guarantee is limited to the legal times allowed only.

According to the *administration of the Austrian North Western and the South Northern*, the use of the ordinary and express trains is regulated by special agreements with the contracting parties.

The time-tables being thus everywhere accurately fixed, it is necessary to make certain that they are adhered to.

Except in the case of the *Italian State Railway*, the information supplied by the different administrations does not refer to any organization of a specially-controlled system for this traffic.

In *Germany*, the wagons loaded with these perishables have labels placed on them indicating the successive trains which are to be used.

Moreover according to paragraph 32 of the general traffic regulations, in order to ensure the transit of wagons conveyed by the trains named, certain stations are instructed in a general way to send to the sorting stations or to the nearest large stations special telegraphic advices which enable them to prepare for the marshalling of their trains; the wagons containing quick-freight goods are naturally placed at the head of the list of wagons which is sent on in this way.

In *France*, on the Orleans system for instance, the important marshalling stations such as Paris must at once point out the irregularities both to the district department to which the station in fault belongs, and to the central administration; they must watch very closely not only over the proper conveyance of the goods, but also over the proper transmission of the papers, which are perhaps more liable to be delayed or go wrong, and without which delivery on arrival might be delayed.

In *Austria*, a special prescription shows all the interest attached to the proper and regular conveyance of this traffic; this is the order to delay every wagon which has gone wrong or is out of order so that it may be added at the next passage of the regulation train.

In *Siberia*, consignments loaded on slow-freight trains must be advised the whole way by telegraph.

In *Italy* finally, the regularity of this carriage of perishables is considered of such an importance that both on the whole system and at the central administration there has been created an organization of control which it appears interesting to consider.

The forwarding station must for each wagon of perishables starting there fill up a detailed route-bill, form G 167, giving in accordance with the general route regulations, the principal stations of the route, together with the indication of the trains to be joined, and the time of arrival and of departure at those stations.

This form serves the conductor as an envelope for the various papers and documents referring to the contents of the wagon; it has spaces provided to receive in succession the stamps of the conductors of the different trains joined, who in this way record the receipt of the wagon.

Moreover, in the list drawn up by the forwarding station, some stations choosed record the trains really used and the real times of arrival and departure; in addition, quite apart from special reports, they eventually record on it any deviations from the prescribed route and any delay which has occurred in the journey of the wagons.

At the end of the journey the terminal station must send the bill to the central administration.

For purposes of control, and in order to ensure the proper forwarding of all these papers, certain stations have the duty of supplying a daily record (form 90) of all the perishables wagons which have arrived or have passed through, the record not being made by means of the route bills which are to be controlled, but by the wagons papers, with their labels or other matters. In addition all the irregularities which have occurred in this special traffic must be recorded.

These records are sent every day to Rome to the central administration and a

special office checks the route-bills in series and compares them with the station reports.

The service so organized is very complete; it might even be thought that it gave much work to the stations where sometimes the time might be lacking for making all these observations while the train was passing; it might also involve a considerable expense of staff.

In answer to these remarks, the administration of the Italian State Railway stated that the route-bill, which serves conveniently as an envelope for the other papers referring to the transport, in most cases requires only very little work at the forwarding station, owing to the simplicity of the routes most frequently used.

The stamping by the train conductors is an extremely easy operation.

As regards the daily reports from the stations, the work has just been simplified by the last service order of March 1909, which has limited their drawing up to the more important stations who must enter all the wagons, and to a certain number of junction stations who only record the movements on the secondary lines, for the connexions on which there is enough times.

Owing to this limitation, the work can now be done without hurry and under favourable conditions.

As regards the central administration, five employees suffice to ensure a proper check, about 6 per cent of the total route-bills being checked, the work naturally bearing on the irregularities recorded in the station records.

The efficiency of the control is moreover proved by the paucity of complaints from the public.

It is also interesting to mention that in order to avoid any inconvenience from the delay or loss of the papers, in the absence of which delivery could often not be effected at arrival, the Italian State Railway has adopted the rule of placing on the loaded wagon a duplicate of the way-bill or of the route-bill, which, should the case arise, fills the place of the actual way-bill.

This measure appears particularly useful in the case of international traffic, the special work of the customs introducing a new chance of error or of irregularity in the transmission of these papers; therefore its utility should be brought to the notice of other administrations. It would however be desirable, in order to lighten the work of the stations, which is always rather hasty and hurried in the case of this special tariff, to ask the public to draw up this duplicate.

In order to appreciate the results obtained with these different organizations, we cannot do better, we think, than give for a certain number of relations the time-tables resulting from the use of the trains designated in the running or route tables.

This information is given in the following table which is compiled either from instances given by the different administrations in their answers to the list of questions, or from documents annexed to those answers.

JOURNEY.	Distance, in kilometres.	Time (1).	Mean inclusive speed, in kilometres.	*Authority.*
		Coming from Italy.		
Bologna-Berlin	1,948	100 hour approximately.	19 to 20	Official French document.
Bologna-Pontebba	976	37 h. 0 m.	26·30	Report to the International Refrigeration Congress.
Bologna-Modane	441	27 h. 10 m.	16·20	Table C (general time-tables of the Italian State Railway). Train FF 5756 and 2002.
Bologna-Chiasso	268	13 h. 45 m.	18·18	Ditto: Train FF.
Castellamare A^{e}-Chiasso	618	31 h. 56 m.	19·30	Ditto: Train PP.
Mestre-Modane	508	37 h. 35 m.	13·52	Ditto: Train 5056 and 5010.
Mestre-Chiasso	299	25 h. 44 m.	15·25	Ditto: Train 5066.
Mestre-Pontebba	185	6 h. 16 m.	29·50	Ditto: Train MM.
Milan-Modane	251	14 h. 0 m.	18·0	Report to the International Refrigeration Congress.
Palenne-Chiasso	1,606	79 h. 0 m.	20·30	Ditto.
Salerne-Modane	1,050	68 h. 45 m.	15·30	Table C (general time-tables of the Italian State Railway). Train GG 5022 and 2002.
Salerne-Chiasso	959	44 h. 0 m.	19·36	Ditto: Train PP and FF.
		Coming from Holland and Belgium.		
Amsterdam-Bâle	744	42 h. 16 m.	17·58	According to the time-tables given by the Dutch Railway Company.
Ostende-Bâle	701	44 h. 51 m	15·60	Alsace-Lorraine book. Appendix, 5, page 186.
Ostende-Cologne	332	11 h. 25 m.	29·04	Bavarian State book. Part 1, page 139.
Rotterdam-Bâle	704	21 h. 14 m.	34·5	According to the time-tables given by the Dutch Railway Company.
Ymuiden-Bâle	760	45 h. 4 m.	16 86	Alsace-Lorraine book. Appendix 5, page 181.
Ymuiden-Bâle	760	35 h. 1 m.	21·66	According to the time-tables given by the Dutch Railway Company.
Ymuiden-Berlin	673	24 h. 7 m. to 42 h. 18 m.	15·90 to 27·9	Ditto.
Ymuiden-Paris-Nord	533	10 h. 23 m.	51·30	Ditto.
		Coming from Alsace-Lorraine, the different German States and Austria.		
Altona-Oderberg	801	40 h. 31 m.	19·74	Prussian State book. Part 2, page 234.
Altona-Breslau	617	31 h. 26 m.	19·60	Ditto.
Geestemeinde-Kufstein	912	49 h. 40 m.	18·40	Bavarian State book. Part, 1, pages 140-141-142.
Geestemeinde-Strasburg	739	49 h. 6 m.	15·0	Alsace-Lorraine book. Appendix 5, page 180.
Kufstein-Cologne	718	45 h. 30 m.	15·80	Bavarian State book. Part 1, pages 140 et 142.

(1) The time required for the journey has been calculated for the international transport without allowing for difference of meridian.

CHAPTER IV.

Means of conveyance (special refrigerator vans, etc.).

The questions dealt with in this chapter includes two parts :

1° Special equipment of wagons of ordinary type;
2° Special wagons (refrigerator vans, constant-temperature vans, heated vans, etc.).

1° *Special equipment of wagons of ordinary type.*

This equipment consists most often of a set of shelves in the wagons to take fruit, and in Holland to take cheess, which are placed on trays which slide in.

Double and treble boarding is also frequently put in to wagons for carrying milk and poultry and small live animals.

In Central Europe, in Germany, Austria, Hungary, Holland and also in Russia, hooks are extensively used for hanging up quarters of meat, these hooks being permanently fixed either to the roof of the wagons or to movable cross-beams supported on equally-movable trestles.

Of this equipment part is owned in some countries by the railways, the rest being owned by traders; in other countries the whole is owned by traders.

In the former case, the part provided by the railways is of minor importance; for instance the Saxon State Railway only owns one milk van and four fruit vans equipped with shelves; the Bavarian State Railway has six wagons with meat hooks; the Belgian State Railway has three such wagons and eighteen fruit vans with shelves.

It is thus evident that the administrations cannot meet all the demands of the public, demands which are the more pressing as these gears are generally placed at their disposal free of charge. In order therefore to get rid of the demands it cannot satisfy and the complaints which ensue, the railway must be protected by its regulations; it is curious to note in this respect that this mixed system exists above all in the countries with a strong administration, such as Germany, Austria-Hungary, Russia.

Taking into consideration the habits of the public in the Latin countries and the principles of absolutely equality which are accepted there, it seems preferable that the railway administrations should not adopt this system.

We have just stated that these conveniences are nearly always placed at the disposal of the public free of charge.

In *Germany*, more especially, this absence of charge both going and returning results in a general way both for the equipment provided by the public as well for that provided by the railway, from the provisions of paragraph 56 of the general conditions of the classifications of goods.

The same rule obtains in *Austria-Hungary* and in *Holland*.

In *Russia*, on the Moscow-Brest line, the weight of this equipment is included with the goods when determining the rated weight.

On the *Transcaucasian* lines, the railway places at the disposal of the public shelves, heating apparatus, cooling apparatus, divisions. No mention is made of any charge except in the last case, where it is 2 roubles (*4s.* 3·26*d.*) per wagon.

In *Siberia*, the movable equipment with hooks for the meat is carried free of charge going; but returning a special rate is charged, which is not mentioned.

In *Russia*, as there are not enough heated wagons available the question has arisen (see *Bulletin des transports internationaux*, May 1907, p. 105) of lining the wagons either with felt, or with hay or straw to protect eggs carried during winter against cold.

The railway officials were not in favour of these operations being carried out by the public. In face of these difficulties, the Russian railway Union decided to authorize them, but reserving for themselves the right of having the felt lining put in by the railway, at the expense of the public, for otherwise the operation might damage the rolling stock.

In the countries where the railways have nothing to do with the provision of such equipment, a rather usual system, for instance in Belgium and on some French lines, consists in charging for the weight of the fruit plus the weight of the shelves used for the carriage of the fruit, and to return them either free of charge (Belgium) or at the reduced rates for returned empties (France).

The French Western Railway however carries them free of charge up to a weight equal to one eighth of the whole rated weight.

It seems that the system of charging for their weight, that is to say, treating them like other packing, holds an equitable balance between the customers who use such equipment, and consequently can materially reduce their packing, and the customers who use the ordinary method, as these would otherwise pay more on their packing and would thus be prejudiced.

This system has, moreover, not prevented the development of the use of wagons with such shelves; for in the case more especially of grapes which it particularly suits, about one quarter of the wagons arriving at the Paris-Orleans station are so equipped.

It must be added that their use and the consequent handling makes it necessary to have more ground available at the arrival stations. Now, especially at large stations and at the time when much fruit arrives, the quick-freight stations have only limited grounds available and this is a fact which must be allowed for when considering the questions concerning transport in carriages so equipped.

However this may be, the use of such shelving makes it possible to carry delicate fruit, such as strawberries and grapes, long distances under much more favourable conditions.

Subject to the reserves mentioned above, it should therefore be encouraged and it is for this purpose that the French export tariff provides a rebate of one tenth of the rate for consignments carried under these conditions, this rebate being reserved, be it well understood, to consignments going without breaking load to beyond the land frontier.

This tariff at the same time specifies that such gear is carried free of charge up to a weight equal to one eighth of the rated weight, and also for its return taken apart.

2° *Special wagons (refrigerator, constant-temperature, heated).*

Perishables naturally suffer from being in the wagons if the prolonged stay leaves them exposed too long in summer to the heat which becomes concentrated in the bodies of the wagons, and in winter, to the frost which penetrates those bodies even if all the openings are closed.

Heat is especially to be feared, and for the last few years much ingenuity has been devoted to reducing its effect.

The wagons used for such consignments are more and more constructed with double walls and double roofs, with ventilation by means of louvered openings in the end and side faces.

The wagons are often painted white so as to increase the protection against outside heat.

The use of wagons so constructed is more especially mentioned by the *Belgian State Railway* for the carriage of butter, and by the *Dutch State Railway* for the carriage of cheese, these wagons having shelves with sliding trays as mentioned above.

It is above all developed in France, on the *Paris-Lyons-Mediterranean and the Orleans railways*, and in Italy on the *Italian State Railway*.

Moreover on the latter, which passes through particularly-hot districts, the ventilation is supplemented by special *torpedo* ventilators placed in the roof of the wagons and these make it possible to renew in 100 seconds the air inside the body of a wagon running at a speed of 60 kilometres (37·3 miles) per hour.

On several railways open-work wagons with several decks are used also, for the carriage of milk; finally, there are mentioned some wagons especially intended for the carriage of sea-fish, and some others, however but few, for carrying live fish placed in large tanks, with special machines for circulating and renewing the air.

But for the carriage of these perishables, carriage which continually tends to extend, as we have shown, over greater distances, these different systems are insuffi-

cient palliatives; for there are traffics, such as those in dead poultry and small animals, which practically cannot be carried in ordinary rolling-stock, and where one is compelled, in spite of the great inconveniences which arise, to substitute transports of live animals.

To judge by the experiments carried out everywhere, it is for this reason that the ideas of the railway administrations are becoming more and more concentrated, as far as such longer distances are concerned, up on the use of refrigerator vans. They are, moreover, encouraged in this tendency by the extraordinary results obtained with such special rolling stock in the *United States*, where more than 60,000 of such cars are running, and, nearer home, in *Russia* and *Siberia* where this traffic is quite new but is developing in a very striking manner.

We must, however, guard ourselves against too prompt imitation of those countries :

The *United States*, and *Russia* together with *Siberia* occupy stretches of land which are greater than Europe. The *United States*, more especially, contain a large population very irregularly distributed over regions very different in character, from torrid Florida to the icy lakes on the Canada frontier, from California with a climate particularly suited to the growing of early fruit and vegetables, to New York where very cold winters and very hot summers alternate. Between regions which differ so much, exchange must take place, and owing to the magnitude of the distancees, to the scattered location of the centres of population, the refrigerator car has been and is the necessary and indispensable tool of that exchange.

In Europe, there are similar differences between the climates of different countries, between Naples or Seville and St. Petersburg, between Hyères or Nice and Berlin; but it is essential to note that the United States are inhabited by a homogeneous population, speaking the same language, having the same customs, the same laws; there is nothing, no customs barrier to hinder the circulation of men and goods, while on the contrary Europe is divided into a large number of different countries, where that circulation is obstructed by different languages and different customs, by the variety or absence of regulations, by the customs barriers, and finally by the different gauges in Spain and in Russia.

It is for this reason no doubt that the use of refrigerator vans has as yet only been made the subject of timid experiments limited to short runs inside the different countries, experiments which as a rule have given results but little encouraging. It is for this reason that on the contrary good results are obtained in Russia-Siberia where there are the same favourable conditions of a vast space and a homogeneous people and administration, like in the United States.

Moreover, where these special transports in refrigerator cars are limited to the extent of any one European country, it is evident that they have no great future before them. The comparative shortness of the journeys, the smaller difference and the irregularity in the temperatures, the dispersion of the traffic resulting from

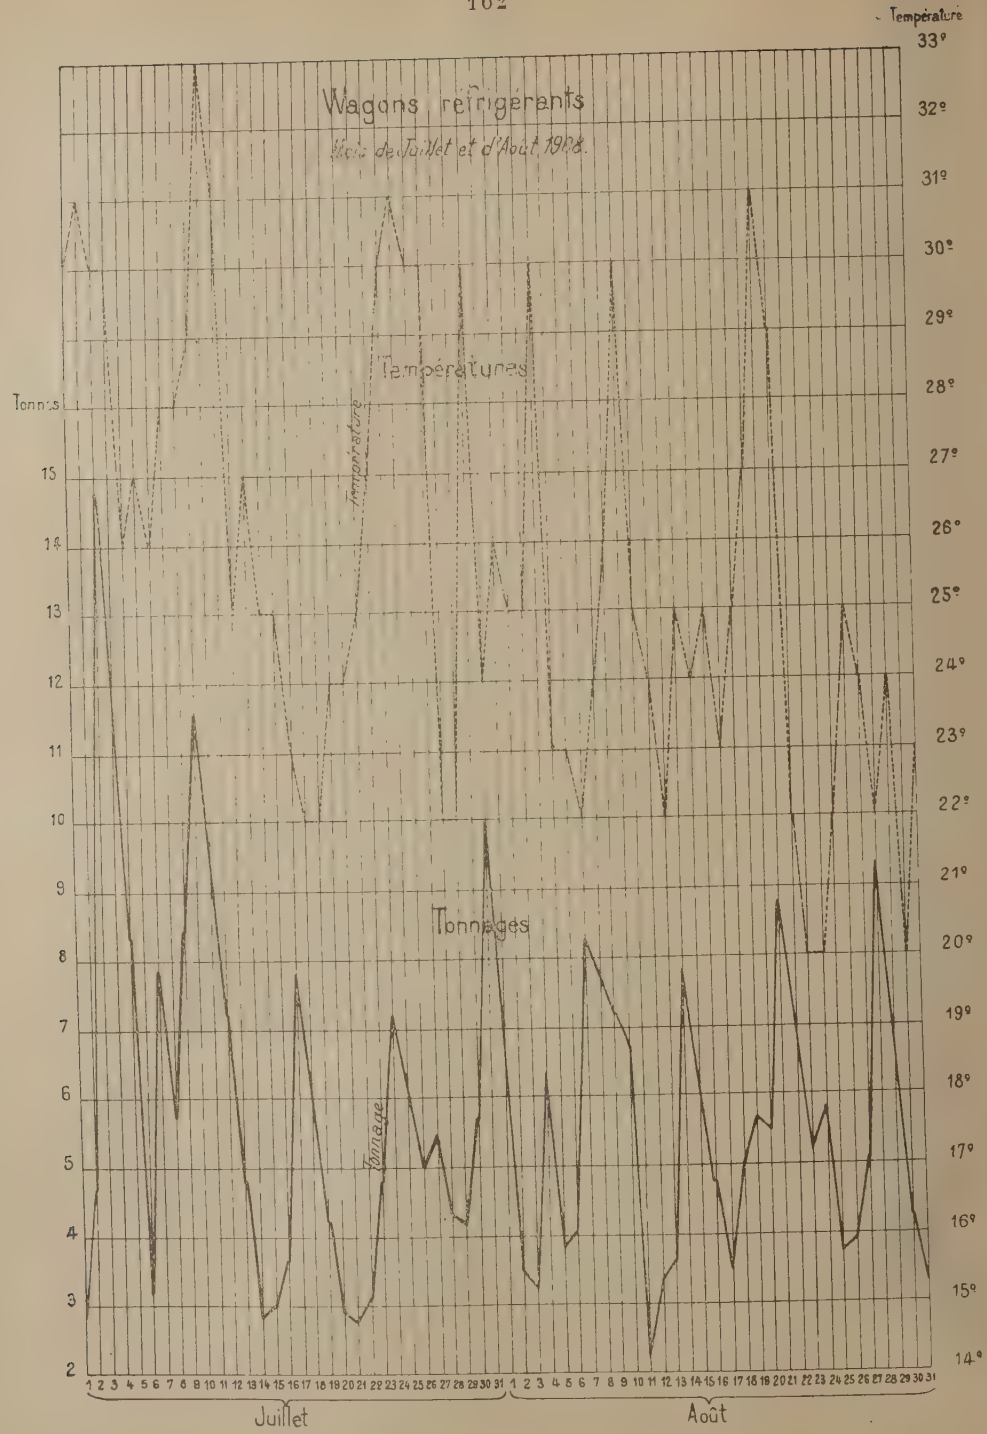

Fig. 21. — Refrigerator van. — July and August 1908.

Explanation of French terms : Température = Temperature. — Tonnages = Tonnage. Juillet = July. — Août = August.

the density of the population, are all causes which must forcibly restrain the growth of this new traffic.

It is in fact evident that trade is but little tempted to incur the expense which the use of such refrigerator vans necessarily involves, for transports which can mostly be effected during the period of one night, and during the coolness of the night. On the other hand a striking instance will show the very great importance of the difficulties arising from the variations in the temperature.

The diagram (fig. 21) shows for the period of 1 July—31 August 1908 the daily variations in the readings of the thermometer at Paris and in the tonnage of the meat brought to the Paris-Orleans station by the daily service of refrigerator vans running to that station.

The nearly-uniform parallelism of the two curves is very significant; it shows that the consignors before handing in their consignments carefully study the thermometer, and according to the results of this consultation choose either the one method or the other, that is to say become resigned or not to the cost of the refrigeration.

It is very evident that daily services can hardly be operated with success, if indeed they can exist, when there is such an irregularity.

This irregularity is moreover also due to the very dispersion of the traffic; the small traders who furnish it can in fact only operate day by day, without considering it to their interest to support a system of transport which is however very advantageous in the hot season.

The results obtained have thus been very mediocre and the tonnage of meat brought in refrigerator vans to the Paris-Orleans station only represents a very small fraction of the total tonnage of that traffic.

In spite of a reduction of 5 per cent in its rates, the French Northern Railway has also had but insignificant results in its carriage of sea-fish from Boulogne to Paris, which is, it is true, but a short distance.

With such results which are approximately reproduced in other countries, it must not be considered surprising if the European railways, Russia excepted, cannot compare with the 60,000 cars of the United States anything except the small stock enumerated in the table below, compiled from the answers received from the different administrations.

RAILWAY.	Refrigerator van belonging to			*Remarks.* *Articles carried.*
	railway.	private owner.	total.	
Alsace-Lorraine	...	12	12	Meat between Holland and Switzerland.
Wurtemberg State	7	...	7	2 milk vans and 5 butter vans.
Baden State.	...	10	10	Vegetable fat.
Prussian State.	113	114	227	63 milk vans, 146 butter vans, 16 fish vans, 2 meat vans.
Oldenburg	...	12	12	Sea-fish.
Bavarian State.	152	...	152	2 butter vans.
Belgian State	20	...	20	Ice and eventually sea-fish.
Austrian State.	156	...	156	Meat, not including 857 beer vans, 781 of which belong to private owners.
Austrian Southern	...	2	2	Fish.
Hungarian State	148	65	213	Meat.
Russian South Eastern . . .	10	...	10	
Moscow-Brest	17	...	17	Heated in winter.
Russian Southern.	27	...	27	19 for fruit, 5 for beer, 2 for dairy produce, 1 for dead poultry.
Moscow-Nijni-Novgorod. . .	18	...	18	Heated in winter.
Transcaucasian	23	....	23	Milk and fruit.
Egyptian State.	One only.	...	...	
Norwegian State.	...	...	...	
Dutch State.	8	...	8	Butter.
Italian State	...	69	69	47 for butter and cheese, 9 for meat, 13 for beer.
French State	13 (1)	17 (2)	30	(1) Butter and meat. (2) Butter.
French companies	...	72	72	Meat, poultry, butter, fruit, sea-fish.
Total (Siberia excluded). . .	712	373	1,085	

This table at once gives rise to the same observation which was already made in the case of the special equipment : namely that the railways chiefly supply those wagons in the countries where they are best protected by the regulations and by the

general discipline of the public against the complaints which must no doubt arise from refusals resulting from the insufficient supply of this special rolling stock.

Moreover, a useful indication is given by this characteristic fact that in the different countries these refrigerator vans are chiefly used for carrying meat, butter, sea-fish, articles which are always being produced, in nearly constant quantities, and which can be more depended on than fruit, vegetables, than irregular and momentary business, to supply the services of refrigerator vans regularly.

The table given above does not include the Siberian rolling stock, because the progress of this special traffic on the railway system of that country is instructive and therefore deserves special mention (1).

It was in 1894, soon after the construction of the Transsiberian, that the export of butter from that country began; but it only assumed special importance when the Russian government wisely decided to help that budding industry by a whole series of measures calculated to promote the establishment of cold-storage depots and by organizing a service of refrigerator vans.

During the last few years, for instance, it authorized the importation, duty free, of about 7,000 tons of articles used for refrigerator plants.

At the same time the government took care to increase its stock of refrigerator vans, which for export butter alone was as follows :

1898. . . .	0	refrigerator vans.	
1899.. . . .	50	—	—
1900. . . .	100	—	—
1901. . . .	370	—	—
1902. . . .	866	—	—
1906. . .	1,050	refrigerator vans.	
1907. . . .	1,292	refrigerator vans out of a total of 1,862 refrigerator vans in Russia.	

In order to supply these vans, a series of ice stores was established along the lines, which increased from 18 in 1898 to 42 in 1900 and 77 in 1907, having a total capacity of 150,621 cubic metres (5,319,419 cubic feet), and so spaced that the distance between any two does not exceed 266 kilometres (165 miles); this maximum is reduced to 170 kilometres (106 miles) on the Transsiberian line and thus enables ice supplies to be obtained twice a day.

This system is supplemented by cold-storage depots at the chief forwarding stations, namely Ob, Kainsk, Omsk, Petropavlovsk and Kourgan; these are intended to receive and store butter pending its despatch.

Finally, there are also cold-storage depots at the chief Baltic ports, constructed either by the State or by private companies, which receive and store butter pending its dispatch by sea.

Without entering into the technical details of the construction of these vans and stores, it is interesting to know that the net cost of the refrigeration by the refrige-

(1) The information which follows has been extracted from the papers submitted by the Russian committees to the International Refrigerator Congress held at Paris in October 1908.

*

rator vans, including all the expenses of the wagons and depots and the interest and amortization of the capital outlay, amounts to 0·81 copeck per pood per day of refrigeration, or 0·91 franc per ton (8·88*d*. per English ton) per day, or 18·10 francs per ton (14*s*. 8·55*d*. per English ton) for the whole journey to the Baltic ports.

This whole scheme planned on such bold lines and carried out very quickly in spite of the disturbance caused by the Russo-Japenese war, has had the very decisive results shown in the following diagram (fig. 22) where curves represent the progress of the export of Siberian butter and also the increase in the number of refrigerator vans.

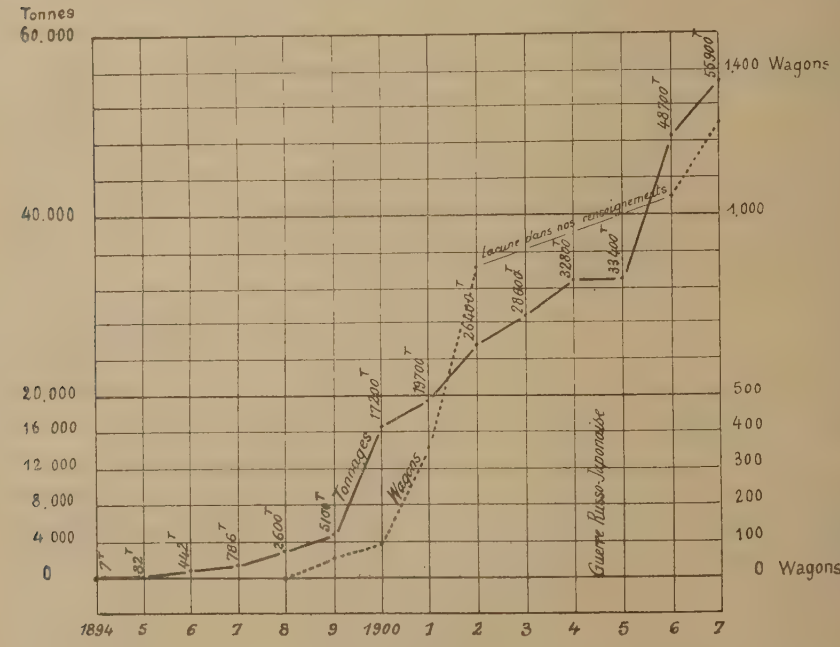

Fig. 22.

Explanation of French terms : Tonnages = Tonnage. — Wagons = Wagons. — Lacune dans nos renseignements = Gap in our information. — Guerre russo-japonaise = Russo-Japanese war.

This result, which does the Russian Administration much honour, gives us a very clear lesson, and that is that for great distances, the use of refrigerator vans is the necessary tool for developing the perishables traffic, is even necessary for its very existence.

If we admit this conclusion and if we recognize the utility of this development in the interests of the well-being of the population and of the railways, it is advisable to investigate all measures possible for facilitating the use of this stock.

In this respect Europe, divided as it is into different nationalities, evidently is not so favourably placed as Russia-Siberia; it seems unlikely that such a result, the organization of similar international services, can be obtained by the disjointed efforts of the different railway administrations.

It is more to be hoped that the future will see the formation of an international company which will be able to effect, for this special traffic, what the International Sleeping Car Company has been able to effect in the case of passenger traffic.

Moreover, it seems rather generally recognized that the supply and operation of these special wagons should not be effected by the railways themselves.

The *Bavarian State Railway*, it is true, expresses the contrary opinion, but with the reserve that on account of the expense it is also advisable to induce the public to provide itself with such stock, and the *Austrian State Railway* has considered it necessary to undertake this service on account of the nature of the meat traffic, *in smaller lots*, which it had to deal with.

On the other hand the *Prussian State*, the *Hungarian State*, the *Transcaucasian* (who own refrigerator vans), the *Italian State*, the *French companies* (on whose lines this particular traffic is also carried in privately-owned stock), have expressed the opinion that the action of private owners is preferable to that of public administrations as regards the selection of suitable rolling stock, the supervision and considerable care necessitated, for instance, by the different temperatures which are most suited to different articles, the quest and retention of a number of agricultural clients who are very scattered and always distrust innovations.

Moreover, from the double point of view of the greater success of private undertakings and the interests of the public itself, a singularly-conclusive experiment is to be found in the simultaneous operation of the two services of refrigerator cars on the French State Railway and on the Orleans Railway; these are operated in two very similar districts on the lines of the two systems, very close to each other, going from Paris to Bordeaux.

Although the official service of the State only demands an extra 10 per cent on the rates while the private company asks for an extra 15 per cent, statistics for July 1907 show that the wagons running on the Orleans Railway line arriving at Paris carried on the average more than twice as much as the wagons of the State line.

Accordingly the railway administrations should not undertake such services themselves, but should limit their activity to the facilitation of the establishment of special companies or even to that of an international company, not only by offering their eventual good-will, but more especially by preparing the field of action by establishing regulations which are uniform and favour the international circulation of these wagons.

Their home regulations at present are very varied; in order at all events to give some idea of the difference and to establish also a basis for any eventual revision, we give in appendix 4 a synoptic comparison of the conditions specified in quick-

freight tariff 121, which has lately come into force for these special wagons after a long investigation of the *French administrations*, of the conditions specified in paragraph 35 of the German tariff, and of the conditions specified in the regulations of 4 April 1908 of the *Italian State Railway*, the two latter applying to all privately-owned wagons.

Unfortunately, this comparison and also the information supplied by the other administrations show that the ground is as yet but ill-prepared for these future refrigerator-van companies.

It is in fact clear that they will not be able to exist except by means of extra rates levied on their customers, over and above the normal railway rates; now nearly everywhere the competition of the railway administrations already makes any such extra rates, and consequently the services themselves, impossible.

In Germany in fact, in Belgium, Hungary, Russia, Norway, the refrigerator-vans which the administrations operate in limited numbers, as an experiment (as the Prussian State says) are placed at the disposal of the public without charging any extra rate. In Austria, the Austrian State Railway only requires the public to supply the ice; in Holland the Dutch State Railway demands an extra rate of 4 francs per ton (3*s*. 3*d*. per English ton); in France, the French State Railway demands a reduced extra rate of 10 per cent; finally in Siberia the extra rate for the entire journey to the Baltic is only 1 kopeck per pood (1*s*. 3·90*d*. per English ton) of butter, while the actual cost is found to be 7·72 kopecks (10*s*. 2·74*d*. per English ton). In all these cases, these extra rates are manifestly lower than the actual cost.

As every service should pay its own way, those concessions cannot be explained *a priori* except by the experimental character which these services seems to have at present nearly everywhere.

No doubt the sacrifices entailed by those modest experiments are of little importance, lost as they are in the general mass of railway operations; but it is just their small magnitude which makes them as a rule useless to the public. They might even be considered injurious, for their mere existence prevents the establishment of private services which could better suit themselves to the varying needs of the different administrations and which seem in fact much better appreciated by the public, as shown in the case of the French State Railway.

In order to clear the future from this point of view and to make possible the establishment and the development of such international services, it seems advisable to withdraw these abnormal favours and ask the public a fair price for this special work.

Or if it seems quite impossible to go back on the existing practice, the railway should deduct from their receipts the sums necessary for properly paying for those particular services, undertaking in place of them the operation of a service which every one recognizes was a particularly-costly one.

But under the existing regulations this solution seems difficultly realizable.

As a general rule, when a railway considers it advisable to accept privately-owned wagons, if these wagons replace its own stock so that it accordingly economizes, it would seem equitable to take this economy into consideration and allow rebates to the owners of these wagons.

Now the *German* regulations contain no proviso to this effect, and the *Italian State* regulations only contain a very uncertain formula.

The *Austrian State Railway* goes even further; it specifies for such wagons a minimum mileage of 5,000 kilometres (3,100 miles) per year on its own system, and charges the owner 2 heller for every kilometre (0·3213*d*. for every mile) less.

Rebates are only found on the following systems :

The *Austrian Southern* grants a rebate of 200 kronen (£8. 6*s*.5*d*.) per wagon per year.

The *Hungarian State* according to the Austrian State allows a rebate to the wagons which can generally be utilized, of 1·8 heller per kilometre (0·2892*d*. per mile), whether loaded or empty, when the annual mileage is between 10,000 and 20,000 kilometres (between 6,200 and 12,400 miles).

Finally there are the *French administrations* which in the case of refrigerator-vans allow a rebate of 0·02 franc per kilometre (0·3090*d*. per mile), whether loaded or returned empty, on the quick-freight rates; this rebate is provisionally increased to 0.045 franc (0·6952*d*.) on the Orleans Railway.

Limiting ourselves to these two most important points and not extending the analysis to other questions of detail, we see that the desired agreement will not be reached without difficulty. It is however indispensable, and should, we think, be aimed at in the directions mentioned, if any appreciable result is to be arrived at and any advance made on a road which may perhaps be prolific of new traffic.

From this point of view finally, it seems necessary to draw the whole attention of the administrations interested to the measures to be taken for facilitating the transit of these wagons at the two frontiers, Russia and Spain, where the break of gauge creates a special and a serious difficulty.

Already systems involving the change of the axles of vehicles have made it possible for a number of slow-freight wagons to cross the Russian frontier without being unloaded; royal orders have just been issued authorizing the application of these systems at the French-Spanish stations of Irun and Cerbère. It is to be hoped that with the active co-operation of the railway administrations concerned these applications will soon be extended to the transit of quick-freight perishables wagons and especially to that of refrigerator-vans.

CHAPTER V.

Claims.

At the commencement of chapter II, dealing with tariffs, we explained in a general way the situations and the ideas which in the different countries had guided the railway administrations in the establishment of their tariffs, and we mentioned among other matters the profound differences which exist in their manner of looking at the responsibility of the railways to the public.

In the case of the perishables traffic, these differences affect above all the question of delays, the most important question affecting this traffic. As regards the other causes of claims, loss and damage, there is much the same protection everywhere against the complaints of the trade and of the public, but we think that from this point of view the different countries can be divided into two distinct groups.

Firstly there are those, generally the countries with strong administration, where the railway systems are principally operated by the State which is therefore interested in protecting their receipts; secondly there are those, principally the Latin countries, where the bulk of the railways are still in the hands of private companies which are consequently less well protected or defended by the State, and which in addition have to reckon with public opinion and tribunals less imbued by the sentiment of the general interest.

Thus we see the restrictive rules of the Berne International Convention reproduced without any alteration or even with aggravations in the home regulations of Germany and Austria-Hungary, notably article 31 of the International Convention referring to damage which becomes paragraph 77 of the German regulations; in France and in Spain however, not only have the rules of the International Convention not been admitted into the home regulations, but these have been added to since : in France by the act of March 1905 which has modified article 103 of the commercial code so that in all cases of damage the presumption of fault falls on the carrier; in Spain by the new commercial code and by recent Royal orders.

The differences between the state of opinion in these different countries can be well shown by quotations from some of the answers sent to our list of questions; thus according to the *Bavarian State Railway*,

the text of paragraph 77 of the German regulations (which agrees with article 31 of the Berne International Convention) is sufficiently flexible to make it possible to reject any exaggerated claims. It states :

> The attempts of commerce to have this paragraph 77 struck out have remained without result up till now, and also will very probably remain without result in the future; for the railway, unless it wants at the same time to raise its tariffs materially, cannot be responsible for damages the source of which is inherent in the very nature of things.

The *Hungarian State Railway* states that in cases of delay the consignors have a tendency to extend the liability of the railways to the damage to the goods; but the claims made in the courts have not been admitted, the tribunals upholding as regards damage to the goods the text of the Berne International Convention (article 31 states that the railways are not liable except in case of serious negligence).

In *Russia*, the general regulation of the Russian railways go so far as to provide for the eventual intervention of the police in the proofs to be produced by the public in support of claims in cases of loss.

According to the *Russian Southern*, the question of limiting the responsibility of railways is on the agenda of the general meeting of the representatives of the Russian railways.

In *Norway* it is specified, with quite an extraordinary profusion of restrictions, that the State Railway is in no way liable unless it can be " proved *without any possible doubt* that the damage or *loss* is *exclusively* due to an *evident* fault or negligence of the railway employees ".

In *Switzerland*, in special tariff No. 4, which concerns the application of the *luggage* system to the carriage of certain perishables, in exceptional tariff making it possible to use all trains, except the through trains, for milk, the railways have inserted clauses which formally limit their liability in cases of delay to the observance, pure and simple, of the ordinary times allowed for *slow-freight*.

In *Belgium*, we find in the general rules for applying the tariffs an article 27, which runs as follows :

The administrations are responsible neither for *loss* nor for *damage*, nor for the *risks* to which are exposed, during conveyance :

1° . . . . . .
2° . . . . . .
3° . . . . . .
4° . . . . . .
5° Goods which are liable to damage from their very nature or from the mere fact of their carriage, such as. . . fresh meat, fresh fish, eggs, fresh fruit and vegetables.

In *Italy*, article 129 of the general conditions releases the railways from all liability for damage and depreciation of goods which are carried at owner's risk and peril. Now this is generally the case with perishables, and slow-freight tariff A No. 55 for such exports contains, for instance, the following clause which has already been referred to :

10° The consignments favoured by this special tariff are accepted and carried at the risk and peril of the consignor, who can claim no compensation from the railway administration for deterioration, damage, natural waste of the goods, unless he can prove that this results from the neglect of the administration.

As opposed to these very peremptory rules and regulations, we find the following information in the answers received from Spain and France :

The *Spanish Northern* mentions the tendency to increase the responsibility, a tendency which has shown itself in the new commercial code and in the Royal orders (referred to above) and in a conference held at Madrid in 1905 and summoned by the government at the request of the chambers of commerce and the industrial syndicates.

In *France*, we have already dwelt upon the tendencies of the extraparliamentary commission which met in 1905 to consider the question of the perishables traffic.

We have already previously referred to the act of March 1905.

The French companies in their answer mention nearly unanimously the tendency there is to increase their responsibilities.

For instance, the *French Northern* states that it manifests itself by new laws, by numerous judgments which are unfavourable to the carrier (1), by the continually-increasing demands of the trade and of the public.

The *Paris-Lyons-Mediterranean* mentions the same tendency of commerce and of the tribunals, to extend the responsibility.

According to the *Midi Railway*, the compensation is now increased by comparatively large " profits missed ".

The " *laissé pour compte* " which are always so burdensome, and with regard to which the tribunals of commerce are generally very strict, become more numerous.

The jurisprudence of the tribunals of commerce tends to increase the responsibility of the railways.

On the *Orleans Railway* the situation is similar.

Moreover, it is everywhere observed that the act of March 1905, by taking away from the railways nearly all their means of defence, has had the effect of promoting the establishment of a large number of agencies who have undertaken the special business of claims against railways and exploit with the greatest activity every incident, even the smallest importance, which can serve as a pretext for a claim or an action-at-law.

Now that we have elucidated the state of the question in different countries, it is advisable to consider these difficulties in detail, in order to seek in the answers, often very summary, sent by the different administrations, the points which are of special interest.

We will adopt the following order in our review : loss, delay, damage (and especially waste).

---

(1) The decisions of the Tribunal of Commerce, when only on matters of fact and without raising a point of law, cannot be appealed against unless the sums concerned exceed 1,500 francs (£60), a sum which much exceeds that involved in most of the suits brought before this tribunal.

Loss.

The *administrations of Central Europe* apply article 34 of the International Convention (paragraph 80 of the German regulations), according to which the compensation given in case of loss only represents the value of the goods at their starting point, and then also limited by the tariff applied.

Nothing is allowed beyond that amount unless there is a special declaration of interest in the delivery, which has to be paid for.

This rule of the payment of the absolute value of the goods is also found in the *Russian* regulations, in the *Dutch* regulations which limit this value to a maximum of 0·60 florin per kilogram (5·43*d*. per lb.) gross, in the *Norwegian* regulations which, as we have already stated, go to the length of only granting compensation in case of *evident* negligence on the part of the railway.

In *Italy*, we find the peculiarity that goods carried under the *general tariff* have compensation paid on the basis of the price at *destination*, while in the case of the special tariff only the price at the *starting* point is taken into consideration, which is naturally lower.

As opposed to this system which obtains in countries with State railways, we find *in France* that the tribunals show a tendency to make allowances, sometimes very considerable ones, for " profits missed ", even in cases where the immediate replacement of the goods accordingly makes it possible to double the profit. As this facility encourages traders, such replacement tends more and more to take place, even in cases of the shortest delays which are then followed by very onerous charges.

Delays.

It is in this case, above all, that the practice in different countries varies very much; it is however essential to observe that the much stricter rules of the French railways have not been imposed on them, but that they have been accepted and even proposed by them with the object of safeguarding, by efficient guarantees, the exceptional measures taken in connexion with the train services and the station services in the case of the perishables traffic; the railways proposed, by these guarantees, to give new and serious encouragement to the development of this traffic.

We will give details of the rules in force in the different countries, referring to the times allowed for the transport, limiting ourselves to the cases of Germany, Italy and France.

In *Germany* the following times are laid down in paragraph 63 of the traffic regulations.

a) Quick freight:

1. Time for service operations	1 day.
2. Time for conveyance per indivisible fraction of 300 kilometres (186 miles) . .	1 —

b) Slow freight :

1. Time for service operations		2 days.
2. Time for conveyance	up to 100 kilometres (62 miles)	1 day.
	beyond and for each section of 200 kilometres (124 miles) more, even if only begun	1 —

We would also recall that as the slow-freight tariffs are in fact applied to a large proportion of the perishables traffic, it is the latter time which has to be considered, together with all the supplementary restrictions which the regulations impose on this traffic.

In *Italy*, the accelerated slow-freight tariffs which are applied to perishables, contain the following conditions :

Accelerated slow-freight tariff 50, for home traffic :

Twenty-four hours for every 225 kilometres (140 miles) of distance; plus eighteen hours for service operations, and six hours for transit between lines under different administrations.

The counted time begins at the start of the first train, after the loaded wagon has been handed in, provided this has been done at least one hour before that start.

The accelerated slow-freight tariff 55 for export traffic applies, as we have already stated, the times of the International Convention, but reducing the distance on Italian lines by 30 per cent.

In *France*, as the text quoted in chapter II shows, the rules fixed by the new tariff include essentially the obligation of the railway to deliver the goods within the two hours fixed by article 54 of the general conditions of application of the quick-freight tariffs, those two hours being reckoned from the booked time of arrival of the train which has in fact conveyed the goods.

Let us compare the results of these different formulæ, taking as an instance a consignment of fruit handed in 1 September, 2 p. m., at the Montauban station to be conveyed to Paris, distance 662 kilometres (411 miles), conveyed by train 6016 starting at 3·5 p. m.

German formula :

1° Application of quick-freight tariff :

The legal time allowed would begin 1 September at midnight and would finish 5 September at midnight.

Total time after handing in the goods . . . . . *106 hours.*

2° Application (ordinary) of slow-freight tariff :

The time would expire 7 September at midnight.

Total time after handing in the goods . . . . . *154 hours.*

With a consignment similarly handed in on Monday 30 August, as the time would expire Sunday night, it would accordingly have twenty-four hours more to run, bringing the total to . . . . . *178 hours.*

Italian formula :

The first train starting being train 6016 at 3·5 p. m., the time starts then and finishes three days eighteen hours later, *i. e.*, at 9·05 a. m. on 5 September.

Total time after handing in the goods . . . . . *91 hours 5 minutes.*

French formula :

Train 6016 is continued from Aubrais on by train 6020 due at Paris at 5·01 a. m. the legal time finishes at 7·01 a. m. on 2 September.

Total time after handing in the goods . . . . . *17 hours 1 minute.*

These examples show that the German and Italian railways, and with them most of the foreign railways, have in fact not to consider this question of delay much.

Be this as it may, the almost-universal rule if the legal time allowed is exceeded, and in the absence of any special declaration of interest in the delivery (which is paid for), is to allow the parties concerned compensation equal to a given fraction of the rate, a fraction naturally increasing with the importance of the delay.

We know the formula of the International Convention which, in the absence of any declaration of interest in the delivery, fixes the compensation at as many tenths of the rate, up to a maximum of $^{5}/_{10}$, as there are tenths of the legal time allowed in the delay.

Paragraph 87 of the German regulations contains a stricter rule with regard to the public.

Counting only delays of more than twelve hours, it fixes the rate of compensation at $^{1}/_{10}$ of the cost of carriage for every whole day of delay up to a maximum of $^{5}/_{10}$ if there is no proof of losses incurred, and up to the whole amounts if such proof is given. In agreement with article 33 of the International Convention, paragraph 79 of the German regulations states, moreover, that the goods may be presumed lost if the delay exceeds thirty days.

In *Russia*, the compensation is calculated at $^{1}/_{20}$ of the rate for each day of delay, up to the total amount of that rate.

Perishables are moreover considered lost and their value can be claimed when the delay exceeds from two to fifteen days, according to the nature of the goods.

Article 25 of the *Belgian* regulations specifies a compensation of $^{1}/_{15}$ of the rate per day of delay, and the consignment may be presumed lost after a delay of fifteen days.

In *Italy*, article 7 of the general conditions for the application of the special tariffs specifies that if the delay is not longer than twice the legal time allowed for the conveyance, the railway can only be held liable for a reduction in the cost of carriage, in accordance with the importance of the delay.

In *France*, the compensation in cases of delay is also reckoned in fractions of the cost of carriage, but the calculation is based on the *hours* of delay instead of the *days*, and it is when the delay exceeds twelve hours that the consignors or the consignees can already claim the profit under common law.

However, as regards the quantity of these compensations for delay the French regulations, as compared with the regulations of the other countries or with those of the Berne International Convention, show an important difference which has to be mentioned.

Actually, these compensations are very frequently granted even if no losses have been incurred, and thus assume the character of a contract, instead of the French tariffs making their payment on the contrary conditional on the proof of a loss incurred.

Finally, encroaching of the subject of damage which we will consider in our next section, we must here say a few words about damage which may be caused by delay, such as for instance over-ripeness.

In the case of such delays, the public has in fact a tendency to urge its claims from this point of view of damage so as to escape the limitations of compensation which result from the special clauses referring to the exceeding of the legal times allowed.

The difficulties raised in this connexion in Hungary have been done away with by the tribunals by virtue of the limitations of the International Convention.

The question appears undecided in Italy.

The French railways have eliminated this source of dispute by inserting in their regulations a precautionary clause which runs as follows :

Condition of the goods. — *The perishables must be despatched in such a condition that they can stand an extra period of twelve hours without deterioration from excess of ripeness or of age.*

Damage.

As a general rule, the questions of compensation for damage are treated in the different countries according to the same principles as in the cases of loss.

The regulations accordingly take generally as basis the absolute value of the goods in accordance with the rules of the International Convention (art. 34) or of similar regulations, such as the German regulations (§ 80); while in France damages plus interest are but too frequently added.

The home regulations of *Germany* (§ 77) moreover repeat the presumption of freedom from liability, which forms the object of article 31 of the International Convention.

We have seen the strict limitations of the *Belgian*, *Norwegian*, and other regulations.

Going further afield, we find that the *Russian* regulations specifically release the

railway from all liability for interior or hidden damage (which can in fact be as much caused by the consignor as by the carrier).

In accordance with article 34 of the International Convention, paragraph 81 of the *German* regulations specifies the establishment of special tariffs which contain, in exchange for more reduced rates, stipulations concerning the maximum compensation to be paid in cases of loss or damage.

Article 130 of the *Italian* regulations provides also for the case of similar special tariffs releasing the railway from all liability unless negligence is proved, etc.

Now all these clauses of absence of liability or of presumption of absence of liability have on the contrary been eliminated from the *French* tariffs by the act of March 1905; in cases of damage the railway now finds itself charged with the presumption of negligence, with the additional difficulty that it most frequently actually finds it impossible, at the forwarding stations, to make all those examinations of the packages which would be necessary for determining the condition of the goods inside.

In the case of perishables which are often consigned in a damp condition and liable to lose weight by the action of the atmospheric influences, it is rational and moreover usual to allow for normal *waste*; the same applies to such articles as eggs which not only cannot be carried without a certain number of breakages occurring, but which are often handed in at the forwarding stations without any practically-possible verification of the damage which may already be present inside, and often actually is present and caused by defective packing or by conveyance to the station on carts without springs or passing over bad country roads.

As regards this question of waste, the rules applying in the different countries vary considerably and often seem very uncertain.

Paragraph 8 of the executory provisions which supplement article 32 of the International Convention and are reproduced in paragraph 78 of the German regulations, include more particularly an allowance for waste amounting to 2 per cent in the case of fresh fruit and to 1 per cent in that of dry goods liable to waste.

But as the *Baden State Railway* informs us, this rule is rarely applied, owing to the great diversity of the circumstances. Thus for instance, the *Prussian State Railway* indicates for eggs a rate of 8 1/3 per cent (1), accepted without trouble by the German traders both for home as well as for international traffic.

According to the *Hungarian State Railway*, in the case of consignments of small live animals, the rate of the waste depends on the conditions of food, drink and health of these animals while on the way, and it is impossible to fix any definite rule.

---

(1) A decision of the Supreme Court of the German Empire (10 October 1906) has quashed a judgment of the Court of Appeal which, not taking into account article 31 of the International Convention, has limited the waste by breakage to 1 per cent (*Bulletin des transports internationaux*, May 1907, p. 188).

In *Russia*, the regulation rate is 2 per cent for fruit, vegetables, eggs, butter; 1 per cent for game, fish, flowers, meat, cheese and dead poultry.

In *Holland* as a rule, a maximum of 2 per cent is allowed per package.

In *Spain*, the rates of waste have been fixed by a Royal ordinance; for instance the *Andalusian Railway* names the following rates :

Vegetables and fruit	5	per cent	in summer	4	per cent	in winter.
Fish carried without ice. . . .	6	—	—	5	—	—
— in ice	12	—	—	8	—	—

The Spanish Northern gives the following :

Eggs : 6 per cent up to 200 kilometres (124 miles) and 2 per cent for every additional 100 kilometres (62 miles), with a maximum of 9 per cent in summer and 7 per cent in winter (1) ;

Butter, fat, poultry, small animals : 2 per cent up to 200 kilometres (124 miles) and 2 per cent for every additional 100 kilometres (62 miles) ; with maximums of 5 per cent in summer and of 4 per cent in winter, in the case of butter and fat; and with maximums of 8 per cent in summer and of 6 per cent in winter in the case of poultry and small animals.

In *Italy*, the question is at present being investigated and it is announced that official tables of these allowances will shortly be published.

At present no such table exists except in special quick-freight tariff No. 3, for the conveyance of perishables as quick freight.

This table fixes among other things the following allowances for waste for every period of twenty four hours and for every 100 kilometres (62 miles) of journey :

Plucked dead poultry in small packages of the following weights :

Up to 50 kilograms (110 lb.).	6 per cent.
— 100 — (220 —).	4 —

LIVE BIRDS.	In truck-loads.	In broken loads subject to transhipment.
1. Turkeys, geese, ducks	10 p. c.	15 p. c.
2. Fowls, chickens, capons	8 —	10 —
3. Pigeons	10 —	15 —

In *France*, there is neither any official rule, nor any generally-recognized table.

Traders have even contested the legality of these allowances for waste, on the

(1) In consequence of the complaints raised against these rates by the traders, experiments will be made to check their correctness.

pretext of the increases in the rates, now abandoned, which had in 1905 been granted to the railways, as compensation for the elimination of the clauses of absence of liability in their tariffs.

However this may be, the following are examples of rates which appear accepted by the ordinary legal practice of the tribunals or by the opinions of the chambers of commerce.

Eggs : 3 per cent (5 per cent for those from abroad) (1);

Live poultry (according to a decision of the Bordeaux Tribunal) : 0·275 per cent per hour from the time of consignment to the time of delivery;

Apples and pears : 2 to 4 per cent according to distance;

Fat : 4 per cent in winter, 5 per cent in summer (French Northern Railway);

Fat and butter : 0·5 per cent up to 200 kilometres (124 miles), 1 per cent for every additional 100 kilometres (62 miles), with maximums of 4 per cent in summer and 3 per cent in winter;

Fish carried in ice : 8 to 30 per cent of the total weight.

All these examples show us definitely that the determination of the rate of waste is made a little arbitrarily in the different countries and even by the different administrations; in any case, the summary rule contained in article 32 of the International Convention and paragraph 8 of the executory provisions is quite insufficient, and no longer meets, even distantly, the needs of an international traffic which is continually becoming more and more important.

It would seem useful to proceed to the establishment of a well co-ordinated list, taking into account the nature of the goods and the consignments (truck-loads or broken loads), also allowing for the distance as in some Italian, Spanish and French formulæ, and for the time required for the journey, as in the formula of the Italian quick-freight tariff No. 3.

Such a table would serve as a guide and support to the railway administrations without however preventing them from investigating and discussing special circumstances eventually leading to coefficients higher than those minima.

CHAPTER VI.

Various measures. — Packing, etc.

Perishables have to fear delays more than ordinary goods; damages can take away their whole value, thefts may result from the temptation they exercise.

---

(1) Leaving out of consideration all the circumstances arising in the case of a traffic in eggs, the Tribunal of Commerce of the Seine has just refused (18 March 1909) to allow for any waste.

Hence, railway administrations are generally induced to surround this traffic with special safeguards, to exercise more careful supervision; they also strive to induce the consignors to take more care in packing and labelling.

1° Measures taken by the railways themselves.

The answers made by the different administrations to this particular question chiefly consist in references to their General Instructions, instructions which hardly ever distinguish between the different kinds of goods, and on the contrary give general recommendations, the exact application of which would no doubt suffice to ensure safe conveyance for the perishables.

Some of them have however thought it advisable to insist upon these recommendations or to add sundry supplementary prescriptions, and we will reproduce information collected in this connection from the answers given or from the instructions annexed to these answers.

Labelling. — *On packages :* that eggs are easily broken is a fact which appears to have been generally considered, for nearly all the administrations put on these packages labels bearing the word " eggs " in large characters, some adding special recommendations such as " fragile ", " this side up ", " with care ", etc.

In order to facilitate the delivery of fruit and vegetables at the Paris markets, the *Orleans Railways* place, in addition to the ordinary label, a special yellow label on all packages forming one and the same consignment; this label bears an order or reference number which is accordingly repeated on all the packages, and one of these labels is stuck on the documents handed to the consignee.

These special labels which are supplied by the railway are moreover often stuck on by the consignors themselves in order to accelerate the departure of their consignments.

The consignments sent to England from the Orleans and the Paris-Lyons-Mediterranean railways have different labels stuck on them, according to whether they go through to London or to places beyond, or to Boulogne or Calais to be sent on from those ports.

On wagons : in order to ensure their quick circulation a large number of administrations prescribe special labels, at least for the principal routes of the traffic. In Germany for instance, placards are often put stating the nature of the contents of the wagon.

The normal labels also have entered on them a list of the successive trains to be used to the destination station.

The *Austrian State Railway* has adopted labels of special and very striking colours for the wagons containing perishables coming from Trieste, the same colour being used for the papers in connection with this special traffic.

Besides the placards stating the nature of the contents, the *Hungarian State*

Railway also adds other special ones with the announcement " Perishables " in three languages : Hungarian, German and French.

In France, on the *Orleans* and *Paris-Lyons-Mediterranean* systems, there are placed on the wagons loaded with perishables for England a certain number of the special labels which are stuck, as we have mentioned above, on the packages which are loaded in these wagons.

Finally as regards eggs, in addition to the labels " eggs " placed both on the wagon and on the packages, other labels are added by many of the administrations, intended more especially to draw the attention of shunting yards to these wagons.

Documents. — In a preceding chapter we have mentioned the useful precaution, taken by the *Italian State Railway*, of placing duplicates of the documents in the wagons.

At Paris, where exchanges between the Orleans Railway and the French Northern make these documents pass through the hands of a certain number of employees, it has only been found possible to regularize their transfer by instituting a special supervision.

The Orleans Railway has moreover obtained good results in a general way by a measure as follows : at each of the important seasons of fruit traffic or early-vegetables traffic, a special official is appointed to watch over all the details of the service in the district concerned, so that he can at once deal with any difficulties which turn up, or can send along the advices necessary.

Miscellaneous measures.

Very generally the different administrations try to meet the temporary needs of the early-vegetables season, the fruit season, the oyster season, etc., by increasing the staff, the appliances, the weighing apparatus, etc.

The only items in the answers sent us, to which we would draw attention are :

The *Midi Railway* uses at the stations on the line between Lamotte and Arcachon, special frames placed on carriages and sliding on the rails.

The *Orleans Railway* puts up light temporary sheds at the stations from which the fruit is despatched.

2° Measures demanded from the public.

Labelling the packages. — The work at the forwarding stations would naturally be much facilitated and rendered more certain by obtaining from the consignors full addresses giving the name and address of the consignee together with the *name of the destination station generally used.*

But here we meet with a very serious difficulty arising from the fact that this

*

business of perishables, as we have already explained, often depends on personal relations, laboriously established between the consignors and the consignees; competitors naturally try to penetrate the secrets, jealously hidden, of these relations; and if full addresses were given, nothing would be easier than for them to do so by simply walking about on the platforms of the stations when these packages are about.

It is for this reason that there has always been the strongest opposition, in our opinion very naturally, to the demands of the railway administrations for proper and complete addresses.

The regulations of most of the administrations accordingly limit themselves to the demand that the labels shall bear the name of the destination station, as well as the number and mark inscribed on the way-bill.

In this connection we find an interesting and very significant proviso in article 2 of the regulation of the *Belgian* State Railway.

This in fact directs the consignors of certain packages weighing less than 60 kilograms (132 lb.) to place on these packages a complete address; but this may be limited to a mark and to the name of the destination station if the consignor hands the forwarding station, together with the way-bill, a separate label giving his address and that of the consignor and also the mark on the package.

In *Spain*, the *Spanish Northern Railway* requires the consignors to attach firmly strong parchment or wooden labels to sacks or baskets containing goods. In the case of consignments going abroad, the labels must bear the name of the consignee.

This latter prescription, which is contrary to the usual practice, is also to be found in *France* in the accelerated slow-freight tariff of the Western Railway and in the common accelerated slow-freight tariff No. 103 of the Western and Orleans Railways for the Brittany sea-fish traffic; but at least as regards the latter traffic, it has been found impossible to compel the consignors to apply it.

In their new quick-freight tariffs, the French administrations have again returned to this question, but authorizing the consignors to hide the name of the consignee under a fold of the label, which is of a pattern now extensively used, and the use of which for broken loads conciliates all the interests; it can therefore, we think, be recommended.

We moreover reproduce the conditions of these new tariffs, which bear on the labelling of the packages by the consignors, drawing attention to the option left to the administration (which they are going to utilize) to require different colours, according to the destinations.

The consignor must place on each package or case a label at least 10 centimetres (4 inches) long and 5 centimetres (2 inches) wide, fixed in a manner that it cannot come off on the way. The use of adhesive material is specially prohibited in the case of packages containing sea-fish.

These labels must bear on them, either openly or hidden under a fold, the name and

address of the consignee; they must also reproduce in a very exact and a very legible fashion the marks inscribed on the way-bill, and also, in large letters, the name of the destination station and of the railway it is on.

The administrations reserve themselves the right of requiring the consignor to use labels of different colours, fixed by them according to the destinations or groups of destinations.

These are rather detailed prescriptions and yet experience shows that in order to avoid difficulties with the consignors it would still have been advisable to enter more into matters of detail and to supplement them by adding a definition of the materials the attached labels are to be made of : parchment, wood, metal, etc.; while paper and card should be excluded; by specifying that several tacks should be used, and not only one, for the fixed labels, etc.

Finally, we think it useful to mention the attempts made by the administration of the *French State Railway* to induce consignors of perishables, particularly of sea-fish, to place inside the package a duplicate of the address so that if the outer label disappears the package can still be dealt with.

Packing. — The packing of perishables has to fulfil several functions.

It must be constructed and closed in such a way as to prevent any theft of these goods, which are more exposed to this than any others.

It must be strong and well arranged inside, so as to protect these delicate goods from damage.

It must have a good appearance outside and be well arranged inside, so that the goods may show up well for purposes of sale.

The first point of view of possible theft naturally receives special attention from the administrations, particularly in the cases of consignments of live poultry, meat, eggs, etc.

Alsace-Lorraine, *Prussia* and no doubt all *the other German administrations* specify in an absolute manner that consignments of meat, when not packed in cases or in barrels, must be in packages which are corded and sealed or lead-sealed in such a way that theft without breaking the seals or lead seals is impossible.

The *Italian State* specifies that the coops or baskets containing poultry or small animals, live or dead, must be covered externally with a net, which is continuous and not pieced together, the meshes not exceeding 2 centimetres ($^{13}/_{16}$ inch) in size; this net must be secured by the seals or lead seals of the consignor in such a way that it is impossible to tamper with it.

In *France the Midi Railway*, instead of these formal prescriptions, insists that the consignors of live poultry shall secure the openings of the coops by means of lead seals, and recommends them to cover the coops with iron wire work.

It demands, and so does the *Orleans Railway* also, that meat should be wrapped

in canvas and sown up with string, which must be in one continuous piece and have its two ends lead-sealed.

The same demand is made in the case of game.

The *Paris-Lyons-Mediterranean* is desirous that in the case of live poultry and small animals the bars of the cages should be sufficiently close together to prevent the animals from putting out their heads.

But all these demands clash with the tendency of the consignors to reduce the cost, that is to say the strength and consequently the security of their packages, a tendency which is now increased by the new law which presumes the responsibility of the railways in all cases and makes it a difficulty for them to resist any claims, however ill founded.

It thus appears necessary, and this is true very generally, not to limit oneself to these attempts, to these recommendations, but to profit by all circumstances, in particular by all reductions in the tariffs to introduce clauses of this kind which would thus become obligatory into the conditions of the latter.

The following clause in the new French quick-freight tariffs still seems too general and too vague from this point of view, except perhaps as regards the packing of meat :

> The packages must be packed in a way which corresponds to the duration of the conveyance and which protects the contents sufficiently well to make it impossible to tamper with them without leaving marks. The canvas in which meat is packed should, more particularly, be sewn up.

As regards *the strength of the packing*, the answers of the administrations deal more particularly with the traffic in eggs, which among the perishables are in fact those which break most readily.

Some *require* the consignors to use proper packing.

For instance the *Hungarian State Railway* specifies a case or barrel made of wood without defects; the spaces between boards must not exceed 3 centimetres ($1\ ^3/_{16}$ inches), it must be hooped at the two ends and at the middle with 3 hoop-wood or with iron-wire plait, 4 to 5 centimetres ($1\ ^9/_{16}$ to 2 inches) wide, nailed to the wood so as to make tampering impossible.

On the other hand other administrations must limit themselves, with doubtful results, to attempting to induce their customers to take certain measures; thus the *French Western* recommends the exclusive use of wooden cases, the *Paris-Lyons-Mediterranean* recommends that the boxes should have handles fixed to them to facilitate their manipulation, and the *French Northern* recommends in a general way that good packing should be used.

Here again, and particularly in France since the act of March 1905, it would be best to have definite and obligatory rules inserted in the tariffs : the *Orleans Railway* has recently recognized this necessity and taken advantage of the establishment of a seasonal tariff to insert in it the following conditions :

External arrangement. — The eggs are packed in cases weighing not more than 110 kilograms (242·5 lb.) each. Cases weighing more than 80 kilograms (176·4 lb.) are divided into two compartments by a cross-partition made of boards.

The walls of the cases may be solid or latticed; the openings must then be smaller than the smallest dimension of the eggs. They must moreover be made of boards not less than 0·015 metre ($^9/_{16}$ inch) thick, firmly nailed to battens at the corners, and must have no projections on the bottom; the small ends must have handles or slots to facilitate the manipulation.

Internal arrangement. — The bottom and the side walls must be lined inside with a thick layer of long straw, not broken; the eggs carefully arranged by layers, of the thickness of an egg. Between each layer of eggs there is a layer of crushed or broken straw of the same thickness. A final layer of long straw is placed on the top in such a way that the cover gives the pressure necessary for keeping the whole in position without crushing the eggs.

Except as regards the thickness of the wood, in regard to which the railway allows some latitude, these conditions have been accepted and are applied without difficulty by the public.

These prescriptions are moreover found, although less detailed, in the rules recently laid down for the construction of egg boxes by the *Kiev District Committe* which in order to obtain a better guarantee against deterioration and theft has decided that in future these boxes are to be constructed of definite size, of strong material at least one inch thick, and that in addition they must have round them hoop-iron or iron wire with the ends lead-sealed.

The frequent thefts which often took place from boxes simply nailed down show that this last precaution, of adding hoop iron or iron wire, already specified on other railways, is far from being useless.

When these conditions, which may be demanded, are not satisfied by the consignors, the usual rule is to make them sign on the way-bill an acknowledgement of the bad or defective state of the packing. These acknowledgements are utilized in case of any difficulties as regards loss or damage.

The *Prussian State* also mentions that in Germany a duplicate of this acknowledgement must in that case be handed to the forwarding station.

On the *Belgian State Railway*, article 2 specifies that this acknowledgement can be demanded from the consignor if the package is in such a condition that it can be rummaged in without breaking it open.

The third condition concerning *the arrangement of the articles inside the package* does not really concern the railways.

It is however not omitted in the recommendations, notices and propaganda, more especially, of the *French railways.*

A large number of administrations moreover take steps to induce the consignors to improve their packing.

The *Prussian State* at the beginning of every season reminds them of its previous recommendations and at the same time requests them to make all efforts to carry out the loading and service operations quickly.

The *Hungarian State* mentions the taking of similar steps.

The *Italian State Railway* goes still further in this direction and joins other parties in giving prizes for the best patterns of packing.

An interesting system is also mentioned in which the Italian State Railway may participate; it consists in placing in the packages of fruit going long distances reference checks according to which those packers whose packages arrive in best condition get prizes.

In *France*, the intervention of the railways, particularly of the *Paris-Lyons-Mediterranean* and the *Orleans*, is very active, and effectively seconds the propaganda of the officials of the Minister of Agriculture and of the agricultural associations.

Pamphlets with photographs of the best systems of packing are extensively distributed, special exhibitions are held, at which lectures are often delivered, at a very large number of the agricultural meetings; in particular, we may mention the *Concours general* held at Paris in 1907 under the auspices of all the French railways jointly.

On the *Orleans system*, since 1902, there have been exhibitions and lectures at Bordeaux, Périgueux, Toulouse, Montauban, Issoudun, Blois, Le Mans, Angers, Limoges, Vannes, Carcasson (Midi), etc.

The *Paris-Lyons-Mediterranean* organized in 1906 in Marseilles a very successful exhibition, with special competitions for packers.

These displays were very well received by the agricultural populations; they have certainly extensively contributed to the improvement which has been noted, during the last few years and very generally, in the condition of the packages and in the appearance of the goods; they have not been without effect on the development of the perishables traffic in France.

CHAPTER VII.

Propaganda of the railways for the development or improvement of production.

All the different railway administrations, except those in France, state that they have taken no part in any propaganda among farmers and traders in order to promote the development of the production of perishables and of the traffic in them.

An exception must however be made in the case of the Oldenburg Railway which

mentions that it built a port for the fisheries at Nordenham for the North Sea fishing companies.

With this exception, the care for such propaganda has been left to special State departments and to the farming associations.

In *France*, the intervention of the railways, their co-operation in the official services, only dates a few years back.

The Paris-Lyons-Mediterranean and the Orleans, in particular, have gone far in this direction and in order to show their activity from this point of view, we cannot do better than quote extracts relating to this propaganda, from the reports submitted to the Chamber of Deputies in connection with the agricultural budget for the year 1909.

PARIS-LYONS-MEDITERRANEAN RAILWAY.

The Paris-Lyons-Mediterranean Railway has moreover not confined its operations to these general organizing measures.

Commercial agents. — It has sent, on mission or even to reside there, commercial representatives or agents to Switzerland, Germany and England, who have studied on the spot the markets available in those countries for fruit and vegetables from Algiers and from southern France, who have ascertained what kinds of packages are asked for by buyers or are suited to the taste of the customers, and then have assisted practically and very effectively, by travels, recommendations, lectures, sundry publications, by entering into personal relations with foreign buyers, with French producers and agricultural syndicates, in forming in other countries, particularly in Germany, a connexion for the purchase of French produce.

Finally, since 1905, the company has been publishing and distributing gratuitously, every year to the parties interested, notices containing useful advice on the subject of exporting fruit and vegetables to Switzerland, Germany, England, Belgium and Holland, particularly on the point of arranging the fruit at different seasons in suitable packages.

Packing. — The question of the packing plays in fact an important part in the fruit and early vegetables traffic. It was necessary to find a standard packing, light and strong at the same time, comparatively low in price and giving perfect protection to the contents. The Paris-Lyons-Mediterranean Railway, with the object of realizing this idea, organized a packing competition at Marseilles; it also took an effective part in different packing competitions which were held successively at Paris, in connection with the agricultural exhibition, at Avignon, etc., by placing at the disposal of the organizers medals and even money prizes which were distributed, on its behalf, among the successful competitors.

Under the title of the united producers of the Paris-Lyons-Mediterranean district, it presented French produce, particularly grapes, to the Mannheim exhibition. This particularly-brilliant exhibition, thanks to the quality of the produce sent by our producers, strongly attracted the attention of German visitors, and particularly that of German buyers

On their side the consignors, profiting by the advice that had been given to them, have gradually abandoned their old systems of cultivation and have resolutely entered the path of improved systems of cultivation. The production has been continually increasing and the statistics eloquently proclaim the success of these combined efforts.

ORLEANS RAILWAY.

Commercial propaganda. — The Orleans Railway has for some years been promoting commercial propaganda both among producers and consignors, as well as among actual or possible buyers in France and in foreign countries.

This began in 1902, by employing the special officials, charged with the supervision of the different seasons of fruit and vegetable traffic, to take steps to induce the consignors to improve their packages, the steps taken being personal advice, lectures, exhibitions. Such improvement is in fact particularly desirable in the case of consignments sent a long distance, either to distant markets in the same country or to foreign markets. In addition to the better appearance and the greater sale-value of articles which look well and are carried under better conditions, the damage is avoided which often discourages buyers and leads them to avoïd markets where packages are deficient.

This special propaganda, the packing exhibitions held at the all the points of the Orleans system, as well as the lectures delivered during the winter season, have had the greatest success among the agricultural population. All these factors have contributed to the very extended movement, which can be observed at present and which may affect the conditions of sale of our produce with the happiest results.

The question of the packing is naturally interconnected with that of the markets.

The company considered that the special trade in fruit and early vegetables depended too exclusively on the intermediary of Paris traders, and that it was advisable to favour direct relations between the producing districts and the consuming districts.

With this object in view, special missions were sent not only to foreign countries, such as England, Germany, Belgium, Holland, but also to the principal markets in the north and the west of France which till then were drawing the greater part of their supplies from the Paris markets.

On the one hand, the resources of the producing markets, the advantages of through rates for carriage, were brought to the notice of the traders, on the other, the information collected at these different places was brought to the notice of the consignors by numerous lectures, by newspaper articles, by pamphlets extensively distributed.

Going still further in this direction, the company took the initiative of organizing in other countries exhibitions of fruit from the south west. Such exhibitions were held with very great success in Düsseldorf in 1904, at Liège in 1905, at Cologne nnd Mannheim in 1907, and paid the exhibitors exceedingly well. In particular, the export to Germany of grapes from the valley of the Garonne was started at these exhibitions.

The most recent steps taken in connection with the propaganda consisted of a very active campaign of lectures delivered in the Lot valley, even in the smallest villages, in order to recommend irrigation methods in that valley which is particularly suitable for market gardens; and in connection with this campaign two exhibitions of motors and pumps were held with every success at Cahors and Villeune-sur-Lot.

Finally, at present, the company has hired a stand at the Arts and Craft exhibition of Brussels, for wine-tasting; the wines of Languedoc and of the Garonne basin are shown there, and the company has obtained for the purpose the co-operation of the chief wine-growers' association and of other syndicates of the south. This has quite a remarkable success with the Belgian public, perhaps significant of new export business. Exhibits of fruit, grapes and nuts are also shown in this exhibition.

On its side, the French Northern, by means of its special representative in England, distributed to the English trade a number of circulars giving information, in connexion with these articles of food, about the resources of the different districts in France, as well as the names of the chief firms selling these articles of food.

At the same time, similar circulars were distributed in France giving the names of the chief buyers in the more important English towns.

It must however be mentioned that this very active propaganda did not go on without giving rise to protests of middle-men who, not concerned about future profits bound to result from the general development of the traffic, saw especially the immediate disadvantage of producers and consuming markets being brought closer together.

A complaint was even brought forward by a chamber of commerce; but it was rejected on the grounds of the general interest by the superior administration as well as by the meeting of the presidents of the chambers of commerce.

This propaganda has moreover one important advantage : by bringing railway officials into permanent contact with the agricultural and the trading world, they on the one hand enlighten it as to its own interests, while at the same time they ascertain its desires and hears its complaints; and it is thus made possible to effect continual improvements in the operation of the train services.

What results have been obtained or may one hope to obtain from these novel methods of the goods departments of the railways? So many different factors come into play in the variations in the perishables traffic and react on each other, that it is naturally impossible to deduce the functions of any one of them.

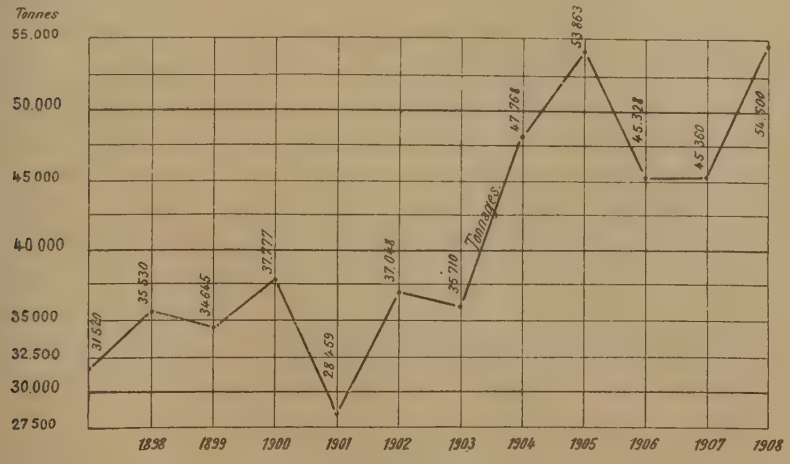

Fig. 23.

Explanation of French term Tonnages = Tonnage.

Nevertheless we have been able to record the direct and very appreciable results which followed from the propaganda in France and in other countries.

Thus for instance we have seen above that the exhibitions organized from 1904 (Dusseldorf) to 1907 (Cologne and Mannheim) resulted in the export to Germany of grapes from the south-west.

We give a curve (fig. 23) showing, from 1897 to 1908, the tonnages of fruit and vegetables sent from the Orleans stations to Paris and beyond (French Northern, export to England and north Germany).

This curve shows a marked increase in this traffic after 1904. Now the activity of these propaganda compaigns dates back to 1902 and 1903, and although the whole progress in the traffic is not to be attributed to them, we may nevertheless assume that it is not totally disconnected.

CONCLUSION.

The principal fact which this examination of the perishables traffic makes clear is that taking it altogether this traffic is progressing considerably.

The increase of the population, the development of general prosperity and well-being, the improvements in land and sea carriage, all help to cause the consumption of these articles of food to increase very quickly everywhere; the continuity of this growth shows clearly that the saturation-point of the international market is far from being reached and that there is still room, and ample room, for all the efforts on the part of exporting countries.

Under these conditions, it is thus not a question of a fight of ejection between these different countries; far from opposing each other, the progress of the one will contribute towards helping the progress of the other; this is shown by the instance of the German market where the new and growing intervention of French trade does not hinder the continuous increase of imports from Italy.

Rather must it be a strife of emulation, in which moreover besides the qualities peculiar to the producers : selection, preparation, condition of the produce, the success will depend less on the rate charged for the carriage than on the care devoted to it, particularly as regards the speed; on the use of suitable rolling stock and on the guarantees given to the consignors by virtue of the conditions of the tariffs.

APPENDIX I.

Milk.

The statistics in annex No. 2 show the great importance and the universal progress in the milk traffic.

This traffic is above all one of very short distances as the following tables show; the one refers to the Berlin supply and the other to the Paris supply; the former is compiled from the statistics for one day, 18 February 1903, by the municipal statistical service of Berlin, the other from information collected in 1892 and 1902 by the railway administrations,

81 to 90 —	66·105	Total. . .	729·960

(1) Weight of cars included.

According to these two examples, consignments from distances exceeding 125 or 150 kilometres (77 or 93 miles) are rare; the instance of Paris, in particular, shows that in order to meet the considerable increase of 65 per cent in its needs, much the greater portion, namely 94 per cent, has been found in this zone of 150 kilometres (93 miles).

The rates for the carriage have but a slight influence on this state of affairs.

It depends, as we know, on the special difficulties of this traffic, on the churning effect produced by the continued vibrations taking place during a long journey, on the necessity of completing a very large number of complicated operations in the short interval between the evening milking and the distributions to the consumers at about 7 o'clock the next morning; such as the collection from the farms which are often at a distance, the Pasteurization, the dispatch, the carriage, the delivery, to destination in town.

However although the influence of the rates for carriage is but small, it must nevertheless not be neglected.

We note in fact that out of 5,385 tons brought to Paris in 1902 from distances exceeding 150 kilometres (93 miles), 5,148 tons were carried on the French Eastern Railway which offers by far the most reduced tariff.

The Orleans Railway reduced in 1905 its tariffs for distances above 120 kilometres (74·5 miles) quite appreciably; the consignments (gross weight) from these greater distances increased from 1,200 tons in 1905 and 1,000 tons in 1906, to 3,100 tons in 1907 and 5,000 tons in 1908.

In Germany during the recent "milk war" in 1905 between the rural producers and the Berlin middlemen, the latter, in order to escape the raised prices which it was desired to impose on them, had to draw their supplies from considerable distances, up to 300 and 500 and even 600 kilometres (186 and 310 and even 372 miles), from Jutland (Denmark).

The rates for the carriage are thus not wholly negligible; this can be understood *a priori* if one considers that the disputes between producers and consumers turn on centimes or fractions of centimes per litre, that these differences become of importance on account of the great quantities

dealt with, and quickly, and that finally, for instance, a difference of 4 francs per gross ton or say 0·005 franc per litre (3*s*. 3·02*d*. per English ton or 0·218*d*. per English gallon) net would in fact represent 5 per cent on the price of the article sold at 10 centimes per litre (4·362*d*. per English gallon) at the farm; that is by no means a negligible fraction of the profit made in this particular line.

However here again it is not possible to consider a systematic lowering in the rates; in examining such a question it must be taken into consideration whether nature, the conditions of cultivation, the rural habits in the new districts which are being considered lend themselves to the production of milk. Even the state of the cattle market has an influence, for we may see, at Beauce for instance, that the production of milk varies with the prices of sheep, of calves; for the farmers tend, if these prices rise, to replace the rearing of cows by that of sheep or to replace the production of milk by the fattening of calves.

Finally, in order to enable reductions in the rates to give any results, it is essentially necessary that the train service is suited to this special traffic.

As it is necessary to collect the milk, after the milking, from farms which are often a long way off from the railway, and to Pasteurize it at depots near the stations, the milk can hardly be sent off before 7 or 8 p. m.; on the other hand in very large towns, owing to the time necessary for delivery at the station, to the extensiveness of the distribution services in the different quarters, above all in the case of stations which are distant from the centres, the last limit for the arrival of the trains seems to be 1 to 2 a. m.

These limited hours peculiarly restrain the distances over which this traffic is practicable; it is consequently evident that the question of the tariffs and that of the transporting operations itself cannot be separated and that they must be studied simultaneously, the second being even more important than the first.

It is moreover in this way that the administrations have proceeded who have given us their special tariffs for this traffic, for nearly all these tariffs have as characteristic the prescription of all the measures favourable for simplifying and shortening the necessarily-hurried operations at stations.

Thus in Germany for instance, the concession of applying the broken-load slow-freight tariff to this traffic which is carried as quick freight, which is generally granted to the greater number of the perishables without particular reservations, is in the case of milk subjected to a whole series of conditions helping to shorten the operations at the dispatching and at the receiving stations.

From this particular point of view, the special tariffs communicated by the administrations of the Prussian State, the Saxon State and the Wurtemberg State give rise to a certain number of observations to which it seems of interest to draw, at least summarily, the attention of other administrations.

In the first place, without making these tariffs into subscription tariffs, strictly speaking, the administrations of the Prussian State and the Saxon State ask the consignor to submit in advance a proposal of traffic, the number of cans to be consigned per day and the trains desired, so as to be able to regulate in this way their means of transport.

Nearly all the work at the forwarding and at the receiving stations is then eliminated by the following measures :

1° The consignors and consignees handle the goods at the stations;

2° In all cases the rate is charged according to the weight or capacity stamped on the cans or

recipients, even if this is not full, the weight charged, in the cases in which the capacity is stamped on, being 1 kilogram per litre (10·02 lb. per English gallon), on the Prussian State (returned empties being charged for), and 1·50 kilograms per litre (15·03 lb. per English gallon) on the Wurtemberg and Baden States (empties returned free);

3° The cans must have metal addresses of a given form and size, on which the weight or capacity is engraved, together with the name and address of the consignor and the consignee. The Saxon State even goes so far as to state that these addresses must be legible by artificial light;

4° The railway has the right of demanding that the upper part of all the cans of one and the same consignment shall be painted a uniform colour;

5° The capacity of the cans must not exceed 40 litres (8·8 English gallons), and the weight of the cans must not exceed 40 kilograms (88 lb.) (50 litres or 50 kilograms [11 English gallons or 110 lb.] on the Wurtemberg State);

6° The clerical work is reduced; the consignor has to draw up and supply way-bills, or the forwarding station keeps a simple monthly account;

7° The empties are returned on receipt of instructions;

8° No advices of arrival are sent out;

9° The carriage is paid at the start, or else accounts are settled every month by the consignor or the consignee, proper guarantees being given.

In addition to the different facilities afforded by these different measures for accelerating the transport itself, the Prussian State and Wurtemberg State administrations receive consignments of milk not only at the stations on their lines but also at a number of intermediate stopping places; this arrangement which is well calculated to facilitate and accelerate the preliminary collecting work, may also be useful in order to facilitate the establishment of depots which is often difficult or impossible in the immediate neighbourhood of the station.

The tariff of the *Swiss Federal Railway* is a *subscription* tariff in two parts.

The first concerns daily consignments consisting of at least 25 litres (5·5 English gallons) consigned *in one lot per day*.

There are three scales of rates according to whether the subscription is for periods of less than 3 months, or for a period of from 3 to 6, or 6 to 12 months; the rates are fixed in indivisible fractions of 5 litres (1·1 English gallons) and include the return of empties free.

Payment is made in advance and the consignor receives in exchange for this payment a number of metal checks representing 0·30 franc (2·88*d*.) each; these are fixed permanently to each can and must not be taken off until the time when the subscription lapses.

As these checks are paid for in advance, all work beyond a simple control is eliminated at the stations.

Extra facilities are moreover granted in the case of all consignments consisting of cans all *having the same capacity*, not exceeding 60 litres (13·2 English gallons).

The second part of the tariff includes the rates payable, in the way of subscriptions, for daily consignments of 1,500, 5,000 or 10,000 kilograms (3,300, 11,020 or 22,050 lb.) per wagon used; these rates are lower than those in the first part of the tariff, at least as far as short distances are concerned, which are of particular importance in the case of this tariff.

In the conditions of this second part we also find detailed prescriptions intended to facilitate the station work.

The cans must be of uniform capacity not exceeding 60 litres (13·2 English gallons).

The cans have to be gauged and stamped.

When not weighed, the weight is calculated at 1·30 kilogram per litre (13·02 lb. per English gallon) of capacity gauged.

The consignor must draw up special way-bills, and all the station has to do is to check them.

The handling is done by the public.

The payment for the subscription is made in advance unless the railway authorizes monthly settlement of the charges for the carriage.

We also see mentioned that wagons are placed, free of charge, at the disposition of the consignor, who can equip them, at his own expense, and that there is an option to make up the loads at intermediate stations, paying however the rate on the full weight from the station at which the wagon starts.

The tariffs of the French railways are very far from presenting such a series of regulations.

We only find it stated, in a general way, that the public must handle the goods at the start and at arrival; and that empties are returned either free or on payment of a booking fee of 0·10 franc (0·96*d.*) and of the tax of 0·70 franc (6·72*d.*).

The tariff of the French Western also contains the proviso that the 2,500 kilograms (5,500 lb.) required in order to benefit by the reduced accelerated slow-freight tariff can be made up at intermediate stations.

Some administrations specify that the weight to be charged for is to be calculated from the capacity of the cans, the French Eastern specifying 1·35 kilogram per litre (13·52 lb. per English gallon) and the Orleans specifying 1·25 kilogram per litre (12·52 lb. per English gallon).

However, in spite of the absence of such conditions in the tariffs of other countries, the service is generally carried out quickly and sufficiently simply, owing to the natural desire of the consignors for quickness, and also, as far as consignments to Paris are concerned, owing to the general use of metal cans known as "*pots de Paris*" having a standard capacity of 20 litres (4·4 English gallons).

The rolling stock used for the carriage of milk does not as a rule present any special features. Nearly everywhere, in order to increase the useful load of these wagons, double-deck wagons are used, which have however the disadvantage of requiring more time and trouble for loading, particularly in the case of broken loads at intermediate stations.

In hot countries or countries of medium temperature like France, these milk vans are constructed with lattices so as to cool the milk by the cold of the night or by the air currents produced by the movement of the train. Ordinary platforms fitted with extra tops are also used for this purpose.

In countries with a lower winter temperature, the tendency appears to be to use wagons with double walls.

The use of refrigerator vans is but little extended and apart from some exceptional cases where the distances are great, it does not appear necessary as the distances are generally short.

Their use will perhaps become more developed in the future with the extension of the zones from which supplies for large cities will be drawn. It must however be mentioned that according to some experiments recently made in connexion with the traffic to Paris, their use for the

carriage of milk will not be unattended with difficulties; for in spite of quite particular care as regards cleanliness, no success has been yet attained in completely overcoming the bad smell which after a very few voyages established itself in the wagons.

It will no doubt be possible to overcome this difficulty and in that case the refrigerator van will be useful not only for the conveyance proper, but also as a store for receiving the morning milking and keeping it while awaiting dispatch after the afternoon milking.

APPENDIX II.

Sea-fish.

Sea-fish has the quite special character of having for a long time been considered an article of food of luxury, and it is still considered as such. In districts far away from the shores, it only very slowly becomes an article of ordinary consumption.

It is for this reason that while the consumption of the ordinary articles of food (vegetables, fruit, meat, butter, eggs, etc.) grows with the purchasing power, that is to say, with the more general prosperity of the comsumers, with the abundance of the supplies brought to market, there has to be in the case of sea-fish a special development in the taste and the habits of the customers.

Thus to the attention devoted to the continually-growing traffic in perishables generally, we have in the case of sea-fish to take special care, on the one hand, in order to facilitate the establishment and development of this special industry of fishing; on the other hand, in order to form a connection of new consumers for this purpose.

Conforming with the logic of this situation, a very large number of administrations have devoted to this traffic greater attention and granted more facilities than in the case of the other perishables.

Some of them have paid most attention to the consumer, and have tried to win him over by reducing their rates, by supplying fresher fish by means of accelerating the traffic, by allowing the division of the consignments to suit the daily needs, etc.; the others have above all devoted themselves to giving all the facilities possible in their land operations to the fishermen and more especially to new fishing undertakings and to steam trawlers.

No doubt there is no absolute line of demarcation between these two methods, and some of the administrations have applied them both simultaneously. But without wishing to draw a formal conclusion, it may nevertheless be shown that even if the future of this traffic depends largely on the care devoted to it by the railways, it is more especially and essentially dependent of the development of the sea fishing itself.

A first example in this connection is shown by the progress of the fishing port of Ymuiden in Holland, where the sales of fish in the market increased as follows :

299,000 mark	(£14,950)	in 1888
560,000 —	(£28,000)	in 1891
1,860,000 —	(£93,000)	in 1900
3,107,000 —	(£155,350)	in 1903
4,073,000 —	(£203,650)	in 1905

Now this growth is to be attributed above all to the progress of the steam-trawling industry,

*

the number of trawlers entering the port having increased, for instance, from 2,754 in 1903 to 3,578 in 1906, codfish boats not included.

It appears evident in fact that on account of the small size of Holland, the government and the railways of that country can only act on a limited Hinterland.

It is however true that the Rhine navigation and consequently the competing tariffs of the railways in the Rhenish districts have given important facilities to this penetration.

The very quick extension of the trade in fish at Geestemünde, at the mouth of the Weser, can also be attributed above all to this development in steam trawling; it is shown in the following table.

YEAR.	Tons of fish caught.	YEAR.	Tons of fish caught.
1896	13,200 tons.	1903	25,200 tons.
1897	13,500 —	1904	25,600 —
1898	14,300 —	1905	28,700 —
1899	14,800 —	1906	36,700 —
1900	16,400 —	1907	35,000 — (1)
1901	17,700 —	1908	31,700 — (1)
1902	22,300 —		

(1) Competition with the port of Cuxhaven at the mouth of the Elbe.

Now this progress certainly seems largely due to the development of steam trawling, as there were four such trawlers in 1887, and this number increased to 37 in 1897 and to 160 in 1905.

The German railways who from 1893 on applied their brokenload slow-freight tariff to the quick-freight traffic in fish as well *as to that in all other perishables*, subsequently introduced, it is true, very reduced rates of special tariff No. S 18 for consignments sent for the German fishing ports only; but if we examine the destinations which benefit by these low rates, we only find stations in Western Germany, in the basin of the Rhine. It therefore seems that this tariff, which begins at the distauce of 200 kilometres (124 miles), has as its object not to facilitate the development of consumption by reducing the cost of carriage, but to assist the German fishing ports in their competition against the Belgian and Dutch ports.

Finally, a very typical instance of the paramount influence of the development of the production on the increase in the consumption is given by the progress of this traffic during the last few years at the stations of the Orleans Railway, which caters for the fishing ports on the south shores of Brittany.

The ports we will thus compare are Pont-l'Abbé, Douarnenez and Concarneau, where only sailing boats are used for fishing, and Lorient, where the use of steam trawlers has been growing the last few years to some extent.

These ports which are very close together are subjected to the same tariffs, and are served by the same trains; thus they are placed under absolutely-identical conditions, so that the results obtained in this case is absolutely conclusive.

Total tonnage of fish traffic from the stations at the ports named below.

YEAR.	Douarnenez.	Pont-l'Abbé.	Concarneau.	Total for these three sailing-boat ports.	Lorient.		
					Tonnage.	Percentage as compared with the tonnage of the three former ports.	Number of steam trawlers.
	Tons.	Tons.	Tons.	Tons.	Tons.		
1904	3,200	2,194	738	6,132	1,745	29	...
1905	3,993	2,714	980	7,687	2,601	34	...
1906	3,601	3,352	1,037	7,990	2,528	32	6
1907	3,901	3,483	1,043	8,427	3,767	45	7
1908	2,976	2,891	681	6,548	6,853	105	12

Thus although the railway takes no special measures, the influx of the fish into the fishing ports thus by itself acts as a certain stimulus to the consumer of the interior, producing, so to say, a spontaneous development of the consumption; this stimulus acts although in spite of the increased supply, the price of the fish tends to rise, if we may believe a report presented 28 January 1908 by Mr. Marcel Charrier to a commercial reunion at Lorient; in this report it is stated that at Boulogne the average price of fish was 0·62 franc per kilogram (2·70*d.* per lb.) in 1894 when steam fishing began, and had increased to 0·785 franc per kilogram (3·42*d.* per lb.) in 1901.

The information as to the increase is confirmed by a paper on *La pêche française à la fin de 1908*, published in the *Bulletin de la ligue maritime française* of April 1909; in it the author gives the following prices for fresh fish at Boulogne : 0·52 franc per kilogram (2·26*d.* per lb.) in 1891; 0·65 franc per kilogram (2·83*d.* per lb.) in 1901; 0·88 franc per kilogram (3·83*d.* per lb.) in 1906. It is interesting to compare these figures, in the following table, with the tonnage of fresh fish dispatched from Boulogne station and with the number of steam trawlers at that port.

YEAR.	Price per kilogram of fresh fish, not including herrings, mackerel and cod.	Quantity of fresh fish dispatched.	Number of steam fishing boats.
1891	52 centimes.	12,500 tons.	3
1901	65 —	27,200 —	55
1906	80 —	45,700 —	108

Finally, similar observations have been made in England where the average price of fish caught

increased from 0·243 franc per kilogram (1·06*d*. per lb.) in 1886 to 0·2716 franc per kilogram (1·183*d*. per lb.) in 1905 (1); and also at Geestemünde where the price increased from 0·26 franc per kilogram (1·13*d*. per lb.) in 1896 to 0·32 franc. per kilogram (1·39*d* per lb.) in 1905 (2); it is true that this price has fallen since.

These repeated instances seem to show clearly that the administrations who devote their efforts to the development and the improvement of the fishing ports, to the facilities to be given at those ports for the victualling of the boats and for the dispatching of the fish, are taking good measures for the development of this special traffic.

In the countries in which the iron roads belong at least to a large extent to the State, such as Germany and Holland, the State, for instance at Geestemünde, at Cuxhaven, at Ymuiden, undertakes the work of constructing these fishing ports and of equipping them ; in England, where the private companies have a happy tendency to consider the ports as their natural extensions (the London and South Western Railway has for instance made of Southampton a very imporant port., it is natural that one of them, the Manchester, Sheffield and Lincolnshire Railway (now the Great Central) should have built and equipped the port of Grimsby, the fishing fleet of which included 489 steam boats and 40 sailing boats in 1903; its fish traffic has increased from 47,600 tons in 1880 to 72,400 tons in 1890, to 130,000 tons in 1901, and to 164,000 tons in 1903.

Moreover, even if we leave out of consideration the development of the traffic and the profits which the railway has consequently earned, these maritime enterprises would not cease to be profitable.

At Grimsby for instance, the total revenue of the port (fish and trade) rose from 814,000 francs (£32,560) in 1891 to 1,780,000 francs (£71,200) in 1905 and to over 2,000,000 francs (£80,000) in 1908, for a total outlay of 15,760,000 francs (£630,400). This would form a very profitable investment yielding 11·3 per cent.

To describe the arrangements at these ports does not enter into the scope of this note; it is enough to say that efforts have been made to reduce to a minimum the different operations as between the boats and the market and the stores of the dealers, and between these stores and the wagons or the forwarding stations. Every advantage has been taken of the local conditions so as to concentrate the installations and thus reduce to the lowest possible limit the cost of handling, both as regards the fish and the victualling of the boats, coal, ice, etc.

Without entering into all these details, it seems however of interest to mention part of the organization devised to facilitate the dispatching operations and to accelerate them, an acceleration which is particularly necessary at Grimsby as sometimes on busy days more than 300 wagons are sent off.

In this port there is an arrangement, which is as interesting as it is simple and practical, which makes it possible to accelerate the loading operations to an important extent.

Three trains consisting of empty wagons which have to be loaded are placed on three parallel tracks which are alongside the platform on to which the offices of the dealers open ; the railway servants have the consignment notes and take and weigh the ready packages which are placed

(1) In 1886 : 565,433 tons valued at 127,287,000 francs (£5,091,480). In 1905 : 973,636 tons, valued at 246,245,000 francs (£9,849,800).

(2) In 1896 : 13,190,954 kilograms (29,081,057 lb.), valued at 3,436,680 francs (£137,467.4*s*.). In 1905 : 28,687,781 kilograms (63,245,690 lb.), valued at 9,303,827 francs (£372,153.2*s*.).

outside the offices, and at once load them into the most distant train, crossing by means of travelling cranes the wagons of the empty trains which are in between.

As soon as this train is loaded, it is removed and another empty train is shunted into its place; in the meantime, without interrupting their work, the loaders in the same way get the second train ready: by means of this system which reduces the number of operations to a minimum, a period of three quarters to one hour is enough for loading a train so that it is ready to start.

At Geestemünde, as at Grimsby, the consignments are taken from the stores of the dealers by the railway which weighs the packages and fills in the consignment notes.

The loading is however not done right opposite the market, but the packages are conveyed by four-wheeled trollies to the loading stages, which are covered and are three in number, with tracks on each side, and can hold altogether 30 wagons.

For this work the railway charges 1 mark per ton (1*s*.0·19*d*. per English ton).

The time necessary for getting a train ready to start is about two hours, which is the time the railway fixes for the consignors.

In order to shorten this time, it was proposed to ask the consignors to sort their packages themselves, which could then be placed on special trollies and taken direct to start for their destinations.

It is also proposed to use electric traction for the trollies which carry the fish from the stores of the dealers to the wagons which are being loaded.

At Cuxhaven, the port and its installations are managed by the Hamburg State authorities; among their staff they have a "chief consignor" who appears to represent the consignors with the railway and whose intervention in such cases materially simplifies the operations.

While at Geestemünde all the loading is effected at the dispatching station, at Cuxhaven on the other hand loading tracks placed along the market make it possible to load *full* truck-loads on those sidings.

At most of the fishing ports of the other countries, particularly in those of France, they are as yet far removed from such favourable conditions, from this endeavour to realize the smallest economies in the movements of the boats, in the handling of their fish and in their victualling.

At Boulogne for instance, which is the most important French fishing port, two carting operations are necessary, one from the port to the store of the dealer, the other from that store to the station, and very often even a third, if the fish goes to the nearest market to be sold by auction.

These troublesome and slow operations, which are repeated with the coal, with the ice, with all supplies, are a heavy burden on the steam fishing, which requires the greatest speed in all these operations so as to reduce to a minimum the time lost on land, and enable it to amortize its large capital outlay and utilize its staff to better advantage.

In addition to the other causes of dearness special to French shipping; high price of coal and ice, bad organization and high auction dues, for which concessions have been often granted to concessionnaires who have nothing to do with the fisheries, these bad conditions of the work at the ports no doubt exercise their influence on the comparatively-high price of fish in France.

In a very documented work on *L'Avenir du port de Lorient*, published in 1909, we read that in 1907 the wholesale price for fish, the average for all kinds, did not exceed :

0·35	franc per kilogram	(1·52*d*. per lb.)	at Ymuiden;
0·25	— —	(1·09*d*. —)	at Geestemünde;
0·25	— —	(1·09*d*. —)	at Hamburg (Cuxhaven);

while in France the average rose to 0·54 franc per kilogram (2·35*d*. per lb.) which is more than double the price averaged in the German ports.

This difference is perhaps partly due to differences in the kinds of fish caught; it cannot, however, be doubted that the defective arrangements at the port play an important part in this exaggerated price which bears heavily on the sea-fish traffic; they certainly contribute in France to the slow development of steam trawling, which is today the essential tool in the progress of fisheries; and yet steam trawlers had their origin in France.

It must moreover be taken into consideration that the multiplicity of the ports, their dispersion along such an extended and broken up coast as that of France, creates *a priori* a much less favourable situation for large steam-trawler enterprises than in Germany, where on the flat shores of the Baltic and of the North Sea there are but few ports, nearly all at the mouth of rivers.

All these reasons explain the difference of the situation which is shown in the following table :

—	France in 1906 (2).	Germany in 1907 (1).	England in 1906 (2).
Sailing boats.	25,000	442 (*a*)	10,000
Steam boats	200	208	2,000
Percentage proportion, steam to sailing	8	47·06 (*b*)	20

(*a*) Only the sailing boats fish outside the territorial water.
(*b*) Only with reference to the deep-sea fishing sailing boats.

In order to counterbalance these greater initial charges, attempts have been made in several countries to improve the conditions of carriage : rate and speed.

In Germany for instance, the organization of the ports being considered satisfactory, sea-fish is carried under the same conditions as all other perishables, except in the case of the very reduced rates of the competition tariffs; in Switzerland, in order to facilitate the arrivals from places which are naturally a long way off, the slow-freight tariff is exceptionally applied to consignments carried as quick freight : in France, as we have seen in chapter II of this report, much lower rates are applied to fish, both for the home tariff and for export, than to all the other perishables.

It seems useless to refer again to the details given in the body of our report, on the scales of rates included in the tariffs of the different countries, on the conditions of speed which are realized; we shall here limit our examination to the questions arising in connection with this particular traffic.

In certain countries, especially in France, its expansion is hindered by the *octroi* levied when entering towns, *octroi* which is frequently so high that it seems based on the old conception of fish as an article of luxury.

Thus an article of food which is sold at the ports at 0·50 franc per kilogram (2·18*d*. per lb.) or even at 0·20 franc per kilogram (0·87*d*. per lb.) in the case of herrings, has to pay duties which amount to 0·40 franc per kilogram (1·74*d*. per lb) at Valencia, 0·25 franc per kilogram (1·09*d*. per lb.) at Havre (1), 0·20 franc per kilogram (0·87*d*. per lb.) at Nimes, and which as a rule reach 0·15 franc per kilogram (0·65*d*. per lb.), as at Toulouse, Avignon, etc.

(1) For sea-fish imported direct without passing through the municipal auction.

These duties which exceed, and that considerably, those levied on meat, which fetches, however, a much higher price, certainly hinder the consumption of fish as an economic article of food particularly useful to the working classes.

A recent enquiry (*Congrès national français des pêches maritimes*, 1907) has shown that the mean annual consumption per inhabitant did not exceed 2 kilograms (4·4 lb. at Lyons, 3 kilograms (6·6 lb.) at Toulouse, 4 kilograms (8·8 lb.) at Lille, 5 kilograms (11 lb.) at Roubaix, and 9·5 kilograms (21 lb.) at Tours and Orleans, while it amounted to 17 kilograms (37·5 lb.) at Nantes and to 32 kilograms (70·5 lb.) at Nice.

Even if we do not count the rural populations who entirely ignore this article of food, we see that there still is ample room for development.

During the course of the enquiry just mentioned, several municipalities which levy duties of up to 150 francs per ton (£6.1*s*. 11*d*. per English ton), thought it advisable, quite forgetting these exorbitant duties, to recommend the reduction of the rates for carriage as a means of promoting this development; it does not, however, seem that such a reduction which perforce could only amount to a few centimes per kilogram, could have any appreciable useful effect

This is proved by the very table of the consumptions at a number of French towns, according to which for instance, Lyons, where there is no octroi duty, shows the low consumption of 2 kilograms (4·4 lb.) per year, while Poitiers with an octroi duty of 0·15 franc per kilogram (0·65*d*. per lb.) shows a consumption of 10 kilograms (22 lb.) per year.

The future of this traffic depends above all on the education which the producers must try to give to the consumers, for instance by facilitating the supplying of large bodies : troops, educational institutions, workmen's cooperative societies, etc., where the taste of the consumers might become developed; by trying to come into closer touch with the consumers by reducing, eliminating or changing the middlemen who by ancient custom, or to cover the risks inherent to this retail trade, sell at present too frequently at much increased prices.

Attempts have already been made in this direction; the fish dealers of Boulogne, Arcachon, etc. have thus entered into direct relations with troops, hospitals, educational institutions, etc.; the important North Sea Fisheries Association, of Nordenham, has established shops for selling direct at a large number of German towns and also at Vienna, Budapest, Bale, etc.

But there is still much to do in this direction and the railways might with advantage study the measures necessary for seconding such organizations.

Moreover a reduction in the railway rates is not a particular wish of the fishing industry; it was not mentioned at the French *Congrès national des pêches maritimes* of 1907; it is not on the list of proposals submitted by the fish dealers of Boulogne to the new 1909 Congress.

Among the list of the wishes of a general character at this Congress, wishes which certainly represent the universal feeling of this special trade, we find the following demands which are repeated more emphatically :

1° Reduction of the time required for the operations at the stations, and admission of the sea-fish into the fastest trains;

2° Application of the tariffs for the quickest routes (instead of the shortest);

3° Reduction of the minimum weight for the application of the special tariffs;

4° Telegraphic advice to the consignor in case of non-delivery at arrival;

5° Reduction in the weight to be charged for, owing to its reduction on the way by the melting of the ice.

As regards the first point, all the administrations in all the countries try to give in practice as much satisfaction as possible; this is more than proved by the information, contained in this report, about the measures taken everywhere with a view to acceleration, and about the results obtained; we have also shown how in France the railways have been led to guarantee these results.

As regards the selection of the quickest routes, we repeat the wish we have already expressed to see this valuable proviso inserted among the conditions of international tariffs, as has been done in the case of the French home traffic.

The question of the lower limit of the weight of the consignments appears to be peculiar to France, where the French Northern has however reduced this limit to 20 kilograms (44 lb.).

In Germany in fact, according to the general conditions of application of the tariffs, the minimum limit of the rates is reduced to 30 pfennigs (3·6*d.*) for broken loads rated under the slow-freight tariff applying to such consignments.

The Italian quick-freight tariff No. 3 fixes it at 20 kilograms (44 lb.); and so on.

The extreme division of the consumption of sea-fish explains the interest which the dealers always assert they have in arrangements organized to facilitate the distribution of their consignments even to the smallest places.

The importance of this may well be gauged by the fact that in 1905, at Boulogne, the number of postal parcels, maximum weight 10 kilograms (22 lb.), was 246,271; these represent, taking 5 kilograms (11 lb.) as the average weight, nearly one third of the whole tonnage dispatched from the station.

This traffic in small packages, sent direct to private people, to small dealers, to schools, has assumed a considerable development in England, in spite of the importance of the general traffic.

According to a report made by one of the French Northern missions, the number of such consignments, packed in light straw fish baskets with handles and weighing, ice included, from 1 kilogram (2·2 lb.) upwards, sent per day from Grimsby, amounts to about 700 and sometimes reaches 1,200; it reaches 4,000 during Lent.

These small packages of fish are charged half the ordinary parcels rates; and if we compare these rates with say the French postal parcel rate, we find material advantages, particularly in the case of the lighter weights, as shown in the following table:

WEIGHTS NOT EXCEEDING.	Rates	
	French.	English.
1 kilogram	0·40 franc.	0·85 franc.
3 kilograms	0·60 —	
5 —	0·90 —	1·05 —
7 —	1·00 —	1·25 —
10 —	1·20 —	

This question of reduced rates for the lower weights seems deserving of attention.

The advantage of advice by telegraph in the case of non-delivery at arrival is evident; the

dealers are thus enabled to take immediate measures for finding other consignees for their goods.

In France, in spite of the offer of the consignors to pay the cost of this advice, resistance to this measure continued for a long time, for fear of introducing new complications in the station service where there are already so many details which have to be attended to. Some administrations have, however, recently decided to make a trial, and this trial is at present going on: it will be interesting to know what results are obtained.

The question of charging on a lower weight than the consignments actually have at the start, in order to allow for the ice melted on the way, is answered in the negative by the majority of the administrations who adhere to the general rule of charging on the actual weight at the start.

No doubt they have thought that a derogation from this general rule would give occasion for other similar demands in the case of other goods; without however attacking this principle, the question could be solved otherwise by a modification of the tariff itself.

In the answers sent to this special question, there are only some German systems, among them the Prussian State and the Bavarian State, which mention that in the case of consignments of fish packed in ice, an allowance of 5 per cent is made in the initial weight.

This question of allowance in the weight to be charged arises in a perhaps more importunate form in the case of live fish conveyed in water, as the dead weight represented by the water necessary is very considerable. The answers of the different administrations give no information about the importance of this special traffic. But if one may judge from the details of the uniform regulations which the different railways of Central Europe have taken the trouble to draw up, we may assume that such traffic is at least fairly frequent.

In France, it is limited to a few consignments of fresh-water fish sent in metal tanks filled with water.

In no case is any reduction made for the weight of the water, and these consignments are charged at the rates of the ordinary tariff for fish.

The uniform regulations mentioned above which exist in Central Europe only include a reduction of 2 pfennigs per kilometre (0·39*d*. per mile) in the fare of the attendant in charge when travelling in the special wagons for looking after the air-circulation mechanism.

Certain administrations draw distinctions between the different kinds of fish, according to their value, and apply more or less reduced rates accordingly.

In Germany for instance the series of exceptional tariffs S 18, for consignments from German ports to the western districts, includes a tariff S 18*b* applying to *herrings*, with rates which are materially lower than those for others kinds of fish.

For instance, the rates from Kiel to Frankfort (chief station) are 25·20 and 21·30 marks per ton (£1.5*s*. 7·25*d*. and £1.0*s*. 9·95*d*. per English ton) in tariffs S 18*a* (fish generally) and S 18*b* (herrings respectively.

On the Russian railways the divisions are more numerous.

In fact it seems anomalous to charge fresh herrings, which have an average selling price not exceeding 0·25 franc per kilogram (1·09*d*. per lb., at the same rate as turbots and soles, which sell at 2·50 and 4·00 francs per kilogram (10·89*d*. and 1*s*. 5·42*d*. per lb.).

The *octroi* offices moreover draw this distinction between the various kinds and generally divide sea-fish into two or three classes on which different duties are paid.

But except in the case of herrings, in which there is considerable traffic at certain times of the

year, the consignments generally consist of different sorts: in consideration of the conditions under which the consignments are dispatched at the forwarding stations, it seems practically impossible to ask these stations to do the work of checking the consignments in such a way as to prevent wrong duties from being charged.

It is remarkable to note that the wishes of the congress referred to above, do not contain any reference to refrigerator vans.

Besides the advantages inherent to the use of such stock for an article of food so eminently perishable, there is in this case the very special advantage of a reduction of weight in the ice placed in the packages and of a corresponding economy in the cost of purchasing and carrying this ice.

But in the home traffic of each country the actual time required is generally so short that this use does not seem necessary.

We have however seen in the chapter dealing with the means of conveyance, that trials are actually being made by various administrations. Traders on their side also show tendencies to utilize these wagons in the case of long-distance international traffic, and these tendencies are naturally to be encouraged.

The use of refrigerator vans is especially very advantageous in the case of crustaceans; in the case of consignments sent from the south coast of Brittany to Belgium, their use has made it possible to reduce very materially the mortality of these animals, a mortality which was often very high when they were carried under the ordinary conditions.

As regards the use of cold for facilitating and regularizing the development of this sea-fish traffic, wishes have been expressed in favour of installing cold storage at the fishing ports.

These stores should receive the fish and store it in dry air with a temperature sufficiently low to preserve it, but not to freeze it, as this would depreciate its value on the European markets.

Instead of the sudden rushes which now result from the daily chances, sometimes favourable and sometimes otherwise, of the fishing, the sales could then be regularized, the excess on days of abundance being stored to supplement the deficiency on days of scarcity.

We can understand that the railway administrations would undertake on their own account the construction and the management of such stores, with a view to the development and the regularization of their traffic. The Orleans Railway studied the question closely in connection with the fishing ports on the south coast of Brittany. It has abandoned these projects, at least provisionally, owing to the difficulties and the want of success it expected to encounter through the indifference of the dealers.

APPENDIX III.

Fresh-cut flowers.

Fresh-cut flowers are essentially a long-distance traffic; thus they are quite the opposite of milk, which as we have seen is nearly entirely a short-distance traffic.

It is perhaps the most delicate article among all the articles carried, the least alteration removing all its value; it requires all the more speed and care, as this traffic is chiefly carried in winter, a season which is particularly dangerous to flowers.

It is only owing to this care and to the speed given to it everywhere, that this comparatively recent (1) traffic has been able to assume the importance it has now assumed, as shown in the following table applying to the systems more especially interested in this traffic.

Tonnage (in tons).

YEAR.	South Russia.		Italian State (Liguria).		Paris-Lyons-Mediterranean. (Provence).

(*) Russo-japanese war.

(1) It was in November 1871 that the first package of flowers intended for sale was sent from the Mediterranean coast to Paris. The invoice price was 4·50 francs (3*s.* 7 1/2 *d.*), and the carriage cost 3·65 (2*s.* 11 1/2 *d.*); total, 8·15 francs (6*s.* 6 1/2 *d.*). It was sold at the market for 84 francs (£3.7*s.* 2 1/2 *d.*), and this was the starting-point of this flower trade which has taken such an extension by now.

As regards the international traffic, the following table gives the imports into England and Germany; the figures are taken from the customs returns of those two countries :

YEAR.	England, value (in pounds sterling)				Germany, weight (in tons)			
	from France.	from Holland.	from other countries.	total.	from France.	from Italy.	from other countries.	total.
1900	125,229	5,496	1,117	131,842	...	...	...	...
1901	139,089	6,236	1,091	146,416	1,021	226	252	1,499
1902	158,883	7,253	1,053	167,189	1,330	401	323	2,054
1903	159,602	6,056	1,145	166,803	1,449	514	376	2,339
1904	144,521	5,676	644	150,841	1,752	552	393	2,702
1905	101,185	5,574	300	107,059	1,440	410	680	2,530
1906	128,184	7,573	346	129,093	1,903	561	449	2,913
1907	120,867	4,251	198	125,316	1,920	506	463	2,889

Thus in addition in the consumption of flowers also, which are an article of luxury, pure and simple, a nearly-certain index of the prosperity of a country, we again find the very characteristic progress of Germany which we already noticed in the case of perishables.

In England, under reserve however of any alteration in the system of valuation adopted by the customs, the imports dropped materially in 1905 and have not yet reached their former level.

In the case of this traffic, it is evident that the rates for carriage are but of secondary importance; however, on account of the extreme subdivision of the consignments they can nearly all benefit by the reduced home or foreign parcel post rates.

A common quick-freight tariff, No. 414, exists for flowers carried from the Riviera by the *trains de luxe* of the international Sleeping Car Company to Vienna, Oderberg, Warsaw, St. Petersburg and seventeen German towns; but according to the answer supplied by the Paris-Lyons-Mediterranean Railway this tariff is used but little.

In the ordinary course of practice, the international consignments are however not sent as postal parcels direct; most of them are sent from the points of origin to transit agents established at Petit-Croix and Cologne for Germany, and at Boulogne for England; these transit agents devote their whole attention to the prompt re-dispatch and conveyance of these packages to their ultimate destinations.

This is another example, in addition to that of the refrigerator vans, that in the case of traffic requiring special care, the public prefers to deal with special enterprises, in spite of greater cost, rather than with the official services of the railway administrations.

In the case of this essentially-delicate merchandize, quickness and care are in fact of paramount importance.

It is largely to an increase in this care and attention that the Italian State Railway attributes the considerable increase in the season 1907-1908 as compared with the season 1906-1907.

We can get a notion of the difficulty of this work if we consider that on certain days, the Paris-Lyons-Mediterranean Railway receives and loads up as many as 20,000 packages of flowers at its stations on the Mediterranean coast.

In 1908, the arrivals at Paris above-mentioned amounted to 86,400 packages in November and to 98,835 packages in December; the maximum on any one day was 5,100 packages on 23 December 1908.

In that same month of December, about 55,000 packages going to Germany passed through Petit-Croix and Cologne.

About the same number was received at Boulogne for transmission to England; as many as 6,000 have been received at London in one day.

In order to do this work, the Paris-Lyons-Mediterranean Railway runs every day a pick-up train which starts from Nice at 1 p. m. and arrives at Marseilles at 5:30 p. m., collecting at the intermediate stations the flowers which are handed in between noon and 2 p. m.

The consignments are placed as collected in specialized vans which at Marseilles are attached to the corresponding fast trains.

This special service makes it possible to deliver flowers, dispatched in the middle of the day from the Mediterranean coast, to the flower shops at Paris on the next day, between 11 a. m. and noon.

By this exceptional use of quick trains, the time required for the journey on the railway has been reduced; thus consignments from Nice, for instance, take 21 hours 15 minutes to Paris, 24 hours to Petit-Croix, 28 hours 20 minutes to Boulogne, 45 hours 43 minutes to Frankfort on the Maine, about 30 hours to London; and when the *trains de luxe* are used, 29 hours 16 minutes to Berlin and 70 hours 55 minutes to St. Petersburg.

This very important service is moreover carried out with the utmost regularity, and a Paris merchant was able to state that out of 35,000 packages sent to him in the winter 1907-1908, nine only failed to arrive.

Although through carriage is in question, without transhipment, and these packages tempt thieves less than articles of food, this result is none the less worthy of notice ; it proves at the same time that proper care has been devoted to the carriage itself, to the quality of the packing and the labelling, both by the railway and by the consignors.

Nota. — The annexes mentioned in this report are published in the *Bulletin of the Railway Congress*, No. 6, June (1st part) 1910, p. 2445.

SECTIONAL DISCUSSION

Meeting held on 11 July 1910 (morning).

MR. COLSON, IN THE CHAIR.

The President. (In French.) — I call upon Mr. Culp to give a summary of his report.

Mr. Culp, *reporter for all English-speaking countries.* — This report does not deal with the question of rates, which from the information obtained from replies received by your reporter, are regulated by commercial conditions, competition and the value of the service to the shippers and receivers, even where the Government authorities fix the maximum rates.

The report deals chiefly with measures to preserve the perishable traffic as nearly as practicable in its original condition even for distances as long as 3,200 miles and for shorter distances. It treats of methods of refrigeration, insulation, ventilation and of the heating of the cars. It furnishes information showing the variations of temperature under methods of refrigeration, insulation, ventilation and heating.

This report deals with the handling of all fresh meats and products of packing houses, with dairy products, such as butter, cheese and milk; poultry, various kinds of fruits and vegetables (sub-divided into highly perishable fruits and vegetables and ordinary perishable fruits and vegetables), with oranges, bananas, pine-apples, fish, and beer in wood. It deals with the methods employed for the preservation in transit of all these various articles to destination in their original conditions as nearly as practicable. It gives a description of the manner in which these articles are prepared for shipment, and shows the details and results of interesting and instructive experiments by the Department of Agriculture of the United States Government in connection with citrus fruits from California to the Atlantic Seaboard.

Reports have been received from the Argentine, England, India, South Africa, Australia and Mexico. Information has been obtained by your reporter from railways of the United States and from other sources in that country. The English-speaking managements, outside of the United States, have not given as complete information as to the refrigeration, insulation, ventilation and heating requirements in their respective countries as might be desired, and this has obliged the reporter

*

to limit his suggestions to practices prevailing in the United States.

The reports from some of the countries named are very complete and elaborate as to methods of loading, description of cars, lists of perishable articles transported, and contain valuable information for which your reporter returns thanks.

Descriptions of various types of refrigerator cars and ventilated cars, and diagrams illustrating the results of the use of these cars in the development of meat, poultry, fruit, vegetable, milk and dairy product traffic in North America are shown. In some instances the increase in the traffic named is very striking.

The report gives descriptions of the kinds of cars and the practices of English-speaking managements of railways other than those in North America.

In the Argentine, the movements are for short distances, and existing facilities are felt to be adequate. No information is furnished as to the measure of refrigerator cars, methods of stowage, or rules for the general conduct of perishable traffic.

The English railways in addition to full description of cars used for the transportation of perishable traffic, give their rules and practices, and report that present facilities appear to be adequate for existing requirements, and no suggestions are offered by those railways looking to further improvements for the increase of the traffic.

Replies from India indicate that the managements of the Indian railways feel that for present demands, their traffic does not require the use of other than ventilated vans or waggons, handled on passenger train schedules, which is their present practice.

Replies from South Africa indicate satisfaction on the part of the shipping agents and the receiving public, from which the conclusion may be drawn that the subject of facilities has received, and is receiving, attention at the hands of those railway managements with the object of fully developing the traffic in perishable goods.

The Australian railways give descriptions and diagrams of refrigerator cars used, also information as to the encouragement of the perishable traffic by the government through the provision of cold storage depots, and by private firms also, and state that the carriers by concessions in rates on fertilizers and manures, are stimulating the production of perishable articles.

Reports from Mexican railways state that the railways use their own refrigerator cars, charge for ice at actual cost and for the actual weight of the load, but offer no suggestions for any change in their present methods and practice. Refrigerator cars are used chiefly for the transportation of beer. Pulque, which is a native vegetable liquor and highly perishable, is nevertheless shipped in cars which in their construction are similar to ordinary live stock cars in use in the United States and Canada.

When the data for this report were procured, arranged and published, the system of cooling fruits and vegetables in the car before the journey had begun (in other words pre-cooling fruit), may be said to have been in the experimental stage. Since that time, much progress in the matter of this system of pre-cooling has been made.

The intermittent vacuum principle or system (known in the United States as the

Sprague system) is referred to in the report, but improvements have since been made in that system, and it is in successful operation at two large fruit shipping markets on the Southern Pacific Railway.

Another system, that of forcing a current of air through the car, driving cold air in through one duct and drawing the warmer air out through another duct, until the car and its contents are properly cooled which is known as the "Gay system of pre-cooling", is in operation on the Atchison, Topeka & Santa Fe Railway. Both of these systems, so far as your reporter can learn from information and examination of the plants and by witnessing the operation of one of them, would satisfactorily provide for the delivery of fruit and vegetables and other perishables at destination over long distances in nearly, or quite, as good a condition as when loaded into cars.

An improvement in connection with the refrigerator car has likewise since this report was published, been devised. This is a collapsible ice tank or bunker, known as the "Bohn" Collapsible Tank Car. It has been installed on a number of cars on the Western railways in the United States. This tank when not in use may be moved to the top of the car and to the ends of the car and fastened there until it is desired to again use the tank, thus increasing the capacity of the car for ordinary freights, it is said 11 per cent for every time used, with an increase in the original cost of the car, including the device, of 10 per cent over the ordinary refrigerator car. This latter expense once made is of course made for the life of the car or of the device.

The report describes an apparatus for heating cars in which is oil used as fuel. Since the report, there have been at least three heaters invented using oil as the fuel, which, it is claimed, are all improvements on the apparatus described in the report. There has likewise been invented and put in use a charcoal heater, known as the "Baxter Heater", which is claimed by at least one very large system using it, to be superior to all the other heaters.

Descriptions, diagrams and photographs of the two systems of pre-cooling, the collapsible ice tank, and the four styles of heaters are in the possession of the reporter, who will, if the Section or the Congress think it of sufficient importance, be pleased to furnish them to the Congress, or make a supplementary report containing information respecting the same. (See appendix.)

The following are the conclusions deducible from my report :

1° That it is essential that the carriers should do whatever may be reasonable to aim at delivering the perishable traffic at destination in good condition, and to accomplish this they should endeavour to have, especially over long distances, thorough expulsion of heat from all highly perishable animal and vegetables substances, exc ept bananas and pine-appels, before shipment;

2° They should aid in the dissemination among producers and handlers of all classes of perishables, of information, of suggestions of improvement in methods of preparation, packing, hours for delivery to the carriers, and reasonable provisions against all possible contingencies of transportation and delivery to the consumer ;

3° That the railways should provide, as far as may be reasonable, the most improved class of vehicles and methods of refrigeration, insulation, ventilation and heating. The tendency

in some countries, notably in the United States, through either governmental requirement or commercial competition, is to require the railways to do this.

Under existing laws in the United States, railways are required to provide refrigeration as a part of the transportation, and while it is at present chiefly done by private companies through arrangement with the railways, the responsibility for furnishing these items of transportation rests with the railways.

If means are adopted to preserve the perishable traffic in transit, the making of reduced rates to stimulate this traffic is unnecessary, and the necessity for moving the trains containing these perishable articles at higher speed becomes of secondary importance, enabling the carriers to reduce the cost or prevent its increase through higher speed, and lessening the grounds for complaint by shippers and receivers as to the condition of perishable goods on delivery at the point of destination.

Mr. Bloch, *reporter for all countries except those using the English language.* (In French.) — The question runs as follows : *Suitable measures for developing the traffic in perishables packing, refrigerator vans, appliances for keeping temperature constant, etc.*

The question may be understood in two different ways : either as including all the questions involved in this particular traffic, or else as limited to the points specially mentioned, namely packing and rolling stock.

In the latter case, the limited results observed in countries other than those using the English language, would have led to drawing up a report of hardly any size.

Therefore it seemed to me more in agreement with the real intentions of the Permanent Commission to take the wider interpretation and study this traffic as a whole. All the more so as Mr. Culp's report, which for many of us is a sort of revelation, gives very complete and interesting details about refrigeration.

My report is divided into several chapters, the titles of which indicate sufficiently the contents : I. Traffic. — II. Tariffs and conditions of liability. — III. Trains and accelerations. — IV. Means of conveyance, refrigerator vans, constant-temperature vans, etc. — V. Settlement of claims. — VI. Various measures, packing. — VII. Propaganda for the development or improvement of production.

Three appendices, which I will not deal with in this summary, consider more especially and investigate, as examples of particular traffics, the cases of milk, sea-fish and fresh-cut flowers.

I. *Traffic.* — This chapter, compiled with the help of the custom-house statistics, studies more especially the international exchanges, that is to say, one of the chief fields of activity of railways.

Examining in succession the traffics of exporting countries and those of importing countries, it deals, chiefly graphically, with the following classes of the more important perishables : butter, eggs, fresh meat, poultry and game, fish and shell-fish, fresh vegetables, fresh fruit.

Summing up the detailed analysis of these different traffics, it is shown that they have grown rapidly under the influence of the development of the prosperity, of the growth of wealth and of population and of the greater facilities given by the railways.

This trade in perishables is still greatest in England; its progress in Germany is also considerable. Its development is specially marked in the case of such produce as fruit and vegetables, in which the outputs of the different countries are to some extent supplementary, and the importing of which accordingly does not meet with any serious opposition.

The same is the case with farm produce, butter and eggs; the growing need for these in industrial districts exceeds the amounts that can be produced in those districts and makes it necessary to go further and further afield.

In the cases of sea fish and of meat, on the other hand, attempts are made nearly everywhere to protect home produce; moreover, especially in the case of meat and of poultry, the risks of conveyance are greater and the producer is not anxious to expose these expensive goods to the risks of long journeys, in rolling stock not fully equipped for the purpose.

All this traffic in perishables, the importance of which is shown in the report, its progress and its tendencies, depend in the long run chiefly on the care bestowed on such transport.

II. *Tariffs, rates and conditions of liability.* — The report shows that the various administrations have generally taken two different points of view. Some, taking into consideration the difficulties of conveying perishables and the extent of the risks run, offer the public reduced rates in exchange for reduced liability; others, in France especially, assume that the value of those perishables is due nearly entirely to the conveyance itself, and accept more limited liability while, on the other hand, keeping the rates sometimes a little high.

In order to decide between these two systems, there is a *judge*, namely the trade itself. That, at least in France and until quite lately, does not ask for reductions in rates, but lays stress on speed and regularity.

There is a *criterium*, namely the results. Now French trade does not play a poor part in the international markets.

Independently of these considerations other reasons, the geographical position for instance, may influence railway rates.

After these general considerations, the report successively considers in detail the tariffs of the different countries, both the home tariffs and the export or international tariffs.

It sets forth more especially the essential difference between the French tariffs, which classify the goods according to their approximate value, applying rates which decrease with the value, and the simpler tariffs of other countries where there is most frequently only one class, sometimes with a few exceptions, as in Italy, in the case of certain articles which are carried at reduced rates.

As regards French tariffs, the report draws special attention to the clause concerning the "specially-designated" trains, which defines the liability of railways in case of delay of trains actually carrying the perishables, and also to a special clause that it should be desirable to give the public the right, in the case of international traffic of this kind, to ask for *the quickest route*, paying of course the rates charged for the distance reckoned for that route.

The chapter concludes with a summary investigation of the influence of reduced tariffs on the development of the traffic;

an analysis of the results of the important general reductions made in France in 1892, in the case of all quick-freight goods and of perishables in particular; the somewhat doubtful results of the 50 per-cent reduction introduced in 1907 in the tariffs for meat in Germany and Austria. All these and other facts lead to the conclusion that general reductions in the rates made *a priori* can only give mediocre or poor results.

At the end of the chapter, the question of the return of empty packages in the different countries is dealt with, and the complications which arise in international traffic in consequence of variations in the exchange.

III. *Carriage. Trains used. Acceleration.* — Subject to the reservation that most of the administrations, except in France, do not enter into any real engagement to carry goods in a given time, all try to reduce this time as much as possible.

Regulations or special provisions for carrying perishables exist in sundry countries. In Italy, in particular, there is a very good organization of special trains for carrying perishables as well as for the conveyance of full wagon loads of these goods.

As a special example worth imitating, I may mention the sending of the way-bill in duplicate, one copy being carried in the wagon containing the goods, the other being used, as in the usual practice, for different operations *en route*.

At the end of the chapter, there is a table compiled from official documents of the various administrations, which shows the mean inclusive speeds of such transports in different countries on a certain number of lines, and illustrates the efforts made in France from this point of view.

IV. *Means of conveyance (special refrigerator vans, etc.).* — Fixed or movable equipment in wagons of ordinary type (shelves, trays, movable cross-beams with meat hooks, etc.) is only used to a rather limited extent; is it either owned by the railways themselves, who place it at the disposal of traders, or else it is owned by the traders.

Except in special cases, the system of carrying this equipment free forwards and backwards seems unfair from the point of view of other traders using the ordinary means, and consequently compelled to pay for the carriage of their packing, which has to be stronger and consequently heavier.

Some of the railways, in particular the Italian State Railway, the Paris-Lyons-Mediterranean Railway and the Orleans Railway, use for this traffic wagons with double walls with a layer of air in between, ventilated by means of openings at the lower and upper parts of the end and side faces.

The Italian State Railway has a type ventilated by means of covered openings extending over the whole height, at the two ends of the side walls, and these openings can be closed by sliding doors.

But do not these large openings allow dust to enter and damage the goods? It would be interesting to have information about this point or about the means employed for preventing this.

Owing to the difficulties which result from the differences of language, of regulations, of custom-houses, etc., the use of refrigerator vans is practically limited to the home traffic of the different countries,

and the total stock of such wagons, in Europe, excluding Russia, does not exceed 1,100 wagons.

That is a very small number as compared with the 60,000 wagons of the United States.

Only in Russia and Siberia, where this traffic is facilitated as in North America, by being under one rule, is this traffic quickly becoming more and more important in the case of butter.

This conclusive result seems to show that the only way to develop this very desirable refrigerator-van traffic is for the different countries in Europe to adopt uniform and common regulations.

A basis for useful and efficacious work from this point of view is to be found in quick-freight tariff 121, which has lately come into force after long investigations, made by the French railways, relating to this special traffic.

In this question of refrigeration, the chief interest now seems to be in the precooling processes which Mr. Culp has mentioned. A trial of them will shortly be made at Château-Renard (Bouches-du-Rhône) by the French section of the International Refrigerator Association.

Mr. Culp, in his report, has given very interesting information which is confirmed by a note sent to me by Mr. Pike, secretary of the Refrigerator Service Association, Chicago.

The resulting tendency is to simplify the cooling operations *en route* and to replace them by cooling at the starting-point. In this way, a very considerable saving has been effected in ice, and there is hope that methods will be found to eliminate the use of ice altogether in the case of short-distance traffic.

V. *Claims.* — This chapter sets forth more especially the different points of view in the different countries : resistance to the claims of the public in the countries with a State system and a strong administration ; augmentation, on the other hand, of the liability of railways in the countries where there are chiefly company railways.

The legal times of delivery in France, Italy and Germany are compared and note is taken of the greater liabilities undertaken of late by the French railways.

As regards damage, the report sets forth the difficulties which cause disputes in connection with waste due to the nature of the goods and with the diversity of the rules applied in determining that waste.

Seeing the growing importance of the international traffic in perishables, the summary rules laid down in article 32 of the Berne International Convention and in paragraph 8 of the executory provisions have become insufficient; the wish is expressed that a well co-ordinated list, taking into account the nature of the goods, the size of the consignments, the length of the journey and the season, should be established, so as to serve as a guide and support to the railway administrations.

VI. *Various measures. Packing.* — This chapter is divided into two parts, concerning respectively the measures to be taken by the railway themselves and those to be demanded from the public.

The former include in particular the labelling of the packages and wagons, which everywhere are made the object of special recommendations in the case of this urgent traffic.

The correct transmission of the papers

is also specially necessary in the case of this traffic, particularly in the case of international traffic, for any delay in the papers, preventing or delaying delivery on arrival, frequently causes trouble.

The practice of the Italian State Railway, to place in the wagons duplicates of the way-bills, is to be recommended. The railway delivering the consignments might also be asked to exercise their discretion, in the case of such a delay, and to deliver the consignments to well-known traders who show sufficiently clearly that they are entitled to them.

As regards the public, proper labelling is demanded and also proper packing, so as to protect the goods both against damage and against theft.

In this case, one recognizes the difference between the State systems, on the one hand, sufficiently armed with their general regulations, and whose demands meet with no difficulties from a better-disciplined public and, on the other hand, the private companies, less protected, who are led to specify in detail, in the conditions of their tariffs, the chief rules which are to be observed by consignors in the labelling and packing of their consignments.

VII. *Propaganda of the railways for the development or improvement of production.* — In all countries, except in France, the care for such propaganda is left to the authorities and to the agricultural societies; in France, the Paris-Lyons-Mediterranean Railway and the Orleans Railway have shown great activity in addition to that of the Minister of agriculture and the farmers' societies.

Dr. Wiedemann, *secretary-reporter*. (In French.) — Mr. Bloch, reporter, proposes some conclusions which differ from those given in the printed report. I have just been informed that they will not be read out, as it is desired that they should first be printed in the *Journal de la session*.

Gentlemen, with the permission of the President, I propose to make two short statements to supplement the very interesting and clear report of Mr. Bloch, concerning the difference of principle specified in the report, in two places, as existing between privately-owned railways and State railways.

In chapter V, which treats of claims, Mr. Bloch takes a first group of countries, with strong governments, where most of the railway systems are operated by the State, and where the claims of the public meet resistance; then he takes a second group, including principally the Latin countries, where the railways are still chiefly in the hands of private companies and where laws and precedents enhance the liabilities of those companies.

In Switzerland, the *legislation* concerning the liability of the railways in cases of delay, loss and damage has remained the same in principle now there are State railways as when these were privately-owned railways. It applies at present alike to the State railway and to private railways. Similarly, the practice of the claims departments, both as regards the home services and the international services, has in no way altered the position of claimants since the State took over the railways. The law department of the general administration of the Swiss Federal Railway, in particular, which has to deal with the application of the International convention for the carriage of

goods on railways, tries, by the equitable settlement of claims, to establish good relations with the public, because it considers it undignified for the State to settle these claims merely from the point of view of self-interest, and because it has been found that traders are then less likely to make claims in cases of minor importance. Nor has Swiss *jurisprudence* become modified since the nationalization of the principal railways. It is, however, observed, at least in French Switzerland, that jurisprudence has become slightly more strict towards the Federal Railway than it was in the case of the private companies.

In the sixth chapter, which deals with miscellaneous measures, packing, etc., the reporter again states that one finds a difference beween State railways and private companies, as regards the labelling and packing of consignments. The State railways are said to be protected by the general regulations laid down by law, the application of which is not opposed by the public. The company railways, the report alleges, are much less protected by the State, and are consequently compelled to issue rules detailing the obligations of consignors as regards labelling and packing.

I consider that that remark also does not apply to Switzerland. Article 11 of the act of nationalization stipulates in fact that the federal legislation concerning railways is applicable to the Swiss Federal Railway, in so far as that application is compatible with the provisions of the said law. The latter is accordingly under the same laws as the company railways. The same is the case from the material point of view : the Swiss traffic regulations and the general provisions of the Swiss law concerning the labelling and packing of merchandise, are obligatory as regards the Federal Railway as much as regards the companies.

It seems to follow from these two remarks that in Switzerland at least the relative position of the State and of the company railways does not show such differences, as regards perishables, as certain parts of Mr. Bloch's report might lead us to believe. Matters must be similar in other countries, and it may be assumed that the State administrations and the company administrations can, on the basis of the conclusions proposed, cooperate, with success, in improving the conditions of carriage of perishables both as regards home traffic and as regards international traffic. It is all the more desirable to arrive at this result, as it is not merely a question of the carriage of *articles de luxe*, but also of really necessary articles (milk, meat, eggs, etc.) intended for poorer people.

The obligation of bringing these articles to their place of delivery in good condition is hence not only a question of increasing the revenue of railways, but also an important proposition from the point of view of public health; and this offers, to all the parties concerned, a field of activity capable of giving much satisfaction.

Mr. Lüttke, Prussian State Railway. (In German.) — In the first place — and I do so with much pleasure — I wish to compliment Mr. Bloch on the very great and frequently admirable care with which his report has been worked out; I will also not criticize it by noting the slight inac-

curacies it contains in connection with the German tariffs and regulations.

The report deals largely with the state of affairs existing in Germany, and I will therefore allow myself to explain, in connection with what is stated in the report, the point of view of the German administrations.

I think the report lays too much stress on the importance of the guarantees given by the railways as regards the speed of the transport, and, on the other hand, it fails to recognize the full importance of cheap rates for certain kinds of perishables, as far as Germany is concerned. The German public, taking it altogether, wishes to have a good transport service at moderate rates. It must be remarked that most of the perishables which are conveyed in that country are generally not of high value, while France exports articles of high value and very perishable (for instance, flowers and grapes). There is also the difference of climate. The German railways, State railways, have, as regards their smaller traders, the duty of making moderate rates for articles of food. The German public, the great majority of it, attaches much greater importance to cheapness as well as to quickness and regularity of transport, than to any greater guarantee of a very short time of delivery. Consignors who wish for such a guarantee must pay the higher rates fixed for express packages. In these cases, the German railways guarantee delivery within a very short time. But most of these goods cannot stand such high rates. Such goods are carried in large quantities. Frankfort on the Main for instance receives and dispatches every day about twenty full quick-freight trains, chiefly loaded with articles of food. It would be absolutely impossible to carry these articles by passenger trains only.

What is considered most important in Germany, I repeat it, is that the perishables should be carried *with great regularity* and with sufficient speed, so that any delays which occur, not as compared with specified times for delivery, but as compared with the shorter times which the public knows by experience, are very rare exceptions. With this object in view, a special service has been in existence for many years. Following the example of Prussia, all the German State railways have now created transport departments, who see that all slow-freight and quick-freight consignments are carried with regularity and with the greatest speed possible, and who look after connections. This department must not be confounded with that charged with drawing up the time-tables; the latter is quite distinct. Excellent results are obtained with this system in Germany and it may be asserted that the public does not ask for greater guarantees, as it knows by experience that the times are sufficiently short and are kept to in most cases.

In order to give an instance of the time within which such transports are affected (it is not exceptionally short, nor is it particularly long), the carriage of ordinary quick-freight consignments, most of which are carried at slow freight rates, only takes twenty-four hours from Frankfort on the Main to Berlin, a distance of 540 kilometres (335 miles). That the cheapness of the rates can contribute largely to the growth of the perishables traffic is also proved by the 1907 tariff for fresh meat, which, according to the report, only gave

mediocre results. I must remark that the reporter, when he drew up his report, could not have had the most recent figures before him; for, thanks to this tariff, the traffic in meat in Prussia increased from 32,000 tons in 1906 (that is, before the tariff was introduced) to 58,000 tons in 1910, and so has nearly doubled. Similarly, from the economical point of view, the adoption of this tariff was not a mistake. The German chambers of commerce are in fact of opinion that it prevented a further rise in the price of meat.

As regards rolling stock, I wish to add a few words to what is stated in the report. The Prussian-Hessian State Raailway owns a large number of wagons equipped, for this traffic, with fixed or movable boards. In particular, good results have been obtained with wagons equipped with hinged flaps which can be folded back against the walls and are arranged in several stories, so that the same wagon can successively be used for fruit, for milk and for other perishables, and also for all other goods.

These special wagons are, however, not placed, in Germany, at the disposal of those who send full wagon-loads, and who in fact hardly ask for them, for such consignors have their own wagons and see themselves to the proper regulation of the temperature, by means of ice or movable stoves, especially in the case of transports going abroad.

On the other hand, the Prussian railways have for some time been running refrigerator vans, in the interest of smaller traders. These vans run regularly every day, on the trunk lines, in certain quick-freight trains. The same rolling stock is used in winter, and it is equipped with steam-heating apparatus or stoves. Such vans run between Berlin and Frankfort on the Main, between Berlin and Hamburg, between Cologne and Frankfort on the Main, and on other important lines. Every quick-freight train here includes a wagon which is heated in winter, and cooled in summer, in which small packages can be shipped. It is self-evident that these wagons can also be used for international traffic, for carrying small quick-freight packages.

Mr. Elsner, ministry of public works, Germany. (In German.) — Gentlemen, allow me in my turn to make a few short remarks about the two reports which I consider extremely interesting; I wish more especially to say a few words about Mr. Bloch's report.

This reporter criticizes, from the point of view of equity, the fact that in Germany for instance — there are also other countries — the railway administrations do not pay any hire for the use of private wagons. I may remark, as against this, that in Germany private wagons, which run empty, have nothing to pay. That is a favour which in my opinion is at least equivalent to that granted by certain railways, the French companies for instance, who pay hire for the use of private wagons.

In the second place, it is claimed that in Germany the rules regarding liability, and especially those regarding compensation for delay in delivery, are more advantageous to the railways, and consequently less advantageous to the public, than those in force in the international service. That is not the case. In Germany every care is taken, and the higher authorities themselves see to it, that the

home traffic should not be treated less favourably than the international traffic. There is no exception to this principle.

The only instance quoted by the reporter in support of his statement, is paragraph 94 of the German traffic regulations, together with article 40 of the International convention for the carriage of goods on railways.

It must be admitted that calculating the time of delivery by tenths is more favourable to the consignor than calculating it by the complete day, as specified in the German regulations. But, on the other hand, it must not be forgotten that the German regulations give compensation for exceeding the time for delivery, not only when no damage has been proved, but also when there has been no damage. The railways hence cannot raise the defence, sometimes very troublesome for the consignor and accepted by many courts of law, that no damage has been caused by the delayed delivery.

Moreover, under paragraph 94 of the same regulations, the compensation for delay in the delivery can be added to that for loss or damage of the goods.

To sum up, my opinion is, that the public is no worse off under the German regulations than under those of the international convention.

Moreover, I think that the provisions of the latter, at which I have had the honour of collaborating during many years, are quite equitable, and equally protect both the consignor and the railway.

Next I wish to say a work about the conclusions enunciated in Mr. Bloch's report. I know well that the reporter intends to present them to us tomorrow in a new shape; but throughout his report we find the assertion that the cost of the carriage — the tariffs are evidently meant — is only of secondary importance in the case of perishables. I cannot agree with this opinion, at least not in this general form. It is possible that it may be true as regards articles of great value, such as flowers, early vegetables, etc., which form in France the greater part of this traffic. On the other hand, it cannot be asserted, and this has already been remarked, that in the case of articles of smaller value, the cost of the carriage, namely the rates, only play a secondary part. On the contrary the public, especially the poorer people in large towns, have great interest in having as cheap rates as possible for such goods, for milk for instance. It is self-evident that the speed and the regularity of the transport must not be sacrificed in order to obtain reduced rates.

Hence, I desire to amend in the following way the conclusions given in Mr. Bloch's report, the first three clauses of which I wish to retain.

The fourth clause should in my opinion run as follows :

" Rather it must be a strife of emulation, in which besides the qualities peculiar to the producer : selection, preparation, condition of the produce, the success will depend in the first place on the care devoted to the carriage, on the speed above all, on the use of suitable packing and on the guarantees given to the consignors by virtue of the conditions of the tariffs. The amount charged for the carriage (rates) only plays a secondary part, as long as merchandise of high value is concerned. The railways will accordingly do well, both in their own interest as well

as in that of its poorer customers, to devote particular attention to this question."

The conclusions contained in the American report can be accepted with some slight modifications, for in America, and probably also in Russia, particularly in Siberia, the conditions are quite different owing to the enormous distances the goods are carried.

The President. (In French.) — I propose to you to continue this discussion this afternoon; but as the Permanent Commission meets at 2 p. m., I have been requested not to start the sectional meeting before 3 p. m.

On the other hand, several members have asked that the conclusions should be printed before they are put to the vote; we could finish the discussion and proceed to vote the conclusions on Tuesday morning. (*Signs of approval.*)

It is accordingly understood that the discussion will be resumed at 3 p. m. this afternoon and that the vote on the conclusions will be taken on Tuesday morning.

Meeting held on 11 July, 1910 (afternoon).

The President. (In French.) — Mr. Pichler von Deeben will now address the meeting.

Mr. Pichler von Deeben, Austrian State Railway. (In German.) — While congratulating the reporter on the very interesting and complete report he has presented, I think I must support the remarks made by the delegates of the Swiss and the German railways. There can be no question of difference of treatment between State railways and the railways of private companies as regards carriage and packing regulations.

I will be brief; it is enough if I mention that as regards all the points here in question, the Austrian traffic regulations agree word for word with the German traffic regulations. Moreover, the packing regulations are on the whole the same. As regards international traffic, the regulations in force are those of the international convention.

The question of the tariffs applying to perishables which are of importance to the majority of the population in Austria also does not play a secondary part, and thus I fully approve the criticisms made by Mr. Elsner and his proposed amendment to Mr. Bloch's conclusions.

Mr. Silva-Freire, ministry of public works, commerce and agriculture, Brazil. (In French.) — The reports presented to us form the elements of an investigation of a kind enabling us to do useful work, taking as our basis the long practice in the United States.

This question of the perishables traffic has been treated from the point of view of the European railways by Mr. Bloch in all its details; and I only wish to address the meeting in order to draw your attention to the question of the carriage of tropical fruit, especially bananas and pineapples.

The report records that in the United States in 1903, the import traffic alone amounted to three milliards of bananas, and this traffic has increased considerably since.

The banana is found in abundance in tropical countries and it is only the question of transport which hinders the growth of the consumption of that fruit in Europe.

The example of what has happened in the United States shows what results can be attained in a short time, if the interests of the railways and those of the public march hand in hand.

It has to be remembered that there is a season of the year when fresh fruit is lacking in Europe, and if bananas could be carried cheaply as far as the centre of Europe, the railway would have a new traffic, and consequently new resources, and the new trade which would result in consequence would not clash with the trade in European fruit, seeing that the times at which fruit ripens in Europe and in South America are widely different.

It would be easy, if an agreement were made about the carriage of tropical fruit, to find new markets for the latter with considerable profit. It seems to me that from the point of view of railways, that it is a question worth considering.

For several years, we have been finding that transport by refrigerator vans is taking a great development, and one may say that it will develop still further if better-designed vans become available.

When the European railways are in possession of a large quantity of such rolling stock, it is probable that that rolling stock will not be utilized sufficiently at the times when no fruit is gathered in Europe.

That will be the time for using these refrigerator vans for the carriage of tropical fruit.

An agreement from this point of view would be desirable between the carrying companies, and even the governments should help the development of the consumption of bananas, which are whole some fruit.

In the United States, a considerable part of the population in the south lives on bananas. In Brazil, they are also largely consumed; it is a fruit which is recommended by physicians.

The Brazilian government considers this question of exporting tropical fruit a very important one, and has come to an agreement with several shipping companies which on their side propose to help the government and promote the export of tropical fruit.

A trial has been made, and it is stated that a good result can only be arrived at by means of an agreement between shipping companies and railways.

The ports in the south of Europe are more especially those which are able to develop this trade.

You now see how this trade might be extended by means of an agreement which would not only benefit carrying companies, but also at the same time serve economic interests.

The phenomena we have observed in the United States might also be produced in Europe, if we remember that the fruit of the countries in the southern hemisphere can replace in Europe the fresh fruit just at a time when it is not available.

Mr. Timonoff, ministry of ways of

communication, Russia. (In French.) — Mr. Bloch's very interesting report is of special interest to the delegates from my country, for it records the great development which the perishables traffic has made in Russia.

Mr. Bloch does us honour in pointing out that the different special measures taken in Russia for the carriage of Siberian butter have given the desired results and that the way in which this traffic is conducted can be taken as a model.

I should, however, like to be allowed to correct some inaccuracies in the report, and this seems to me all the more important as the perishables traffic in Russia is continually growing.

In order to give you an idea of this, I need only give you some figures. According to a careful investigation made by Mr. Pétroff, the quantity of articles of food, such as fruit and vegetables, carried in 1906, amounted to 155 million poods (2,498,861 English tons), representing a value of 330 million roubles, that is to say, about 40 million pounds.

These figures are enough to show that these articles of food are not exclusively intended for the rich, but also for the middle and to a certain extent also for the poorer classes.

This traffic is in part international traffic, for a great quantity of Russian butter goes abroad, and certain countries, such as Denmark and England, have a particular interest that these goods should be carried under good conditions.

The railway regulations concerning carriage generally and especially the carriage of perishables are extremely strict in Russia. In fact, while the ordinary slow-freight consignments are carried at the speed of 150 versts (100 miles) per twenty-four hours, perishables are carried at that of 400 versts (265 miles).

The regulations are applied with strictness. If the perishables have deteriorated, their price is repaid by the railway and if there is delay, the companies pay compensation.

The government does not favour the railways; on the contrary, it is those who are interested in the consignments, the owners of the merchandise, who are favoured.

In case of any dispute before the courts of law, the railways have to prove that they are not in the wrong, and the courts generally have a tendency to be on the side of the public rather than on the side of the railway.

No difference is made between the railways operated by companies and those operated by the State; both of them are treated in the same way.

The tariffs for the carriage of perishables have been considered with great care both by the railway companies and by the Russian ministry. Attempts were made to favour this long-distance traffic, by applying the principle that traffic should not pay more than it can bear, and thus the result has been arrived at of carrying fruit as quick freight while only charging slow-freight rates.

The sole object of my observations is to show that in Russia the perishables traffic is operated in a way which evidently represents some improvement and that there is reason to believe that if we proceed further in the same direction, we shall succeed in making this traffic grow, which is not only national, but also tends more and more to become international.

Mr. Bloch, *reporter*. (In French.) — I begin by thanking the speakers for the praise they have bestowed on my work. I have tried to contribute my stone towards our common edifice and I am glad I have succeeded in doing it. I still have to answer several criticisms and to clear up a misunderstanding. I never said that in the countries where there are both railways operated by the State and others operated by companies, the powers that be apply different rules. On the contrary, I am convinced that in all the States represented here, everybody has equal justice.

Only in the countries where the railways are chiefly State railways, the regulations contain as a rule conditions which are stricter as regards the public and easier as regards the railways. The German regulations and the Austrian regulations have been mentioned; I think that the difference is a minimum and that the States in central Europe have in reality regulations very similar to those of the Berne International Convention.

In France, on the contrary, we of the railways would be very happy to benefit by such a regime.

Mr. Lüttke has reproached me with laying too much stress on the liability and too little on the effect produced by lowering the rates.

He thinks that the rates of carriage may have a considerable influence on the cost of articles of food consumed by the public, and that it may be advisable to apply reduced rates to the articles of more ordinary quality.

I wish to inform you that in France also we have done much in the way of such reductions in the case of ordinary articles of food.

I now will answer Mr. Lüttke, who has referred to what I have said regarding the effects of the 50-per-cent reduction in the fresh-meat tariff in Germany at a critical period.

I knew nothing of this reduction and I had no idea of the existence of this tariff and I was only informed of it by the answers received to the questions I addressed to the different railway administrations.

Question II-*b*, of the list of questions addressed to the different railway administrations was worded as follows : *Have reductions of any importance been recently made in the tariffs? To what extent? With what object? With what conditions? What result have they given?*

Two or three administrations of German and Austrian railways stated, in answer to this question, that the 50-per-cent reduction in the meat tariff had given no result.

The Austrian State Railway even added that this reduction in the rates, which came into force in 1907 I think, was done away with three months later, on account of the insignificant results obtained.

It is possible that the fresh-meat traffic has taken a certain development since, but what I can definitely state, is that in my report I have in no way modified the bearing of the information supplied to me.

In conclusion, I may mention that in the first paragraph of the conclusions we propose to the section, we consider the rates for perishables intended for popular consumption and we recognize that it can be advantageous, in certain cases, to allow material reductions in the rates.

The President. (In French.)—Mr. Haines, who has put his name down, is not present, and as nobody else wishes to speak, I propose to adjourn the meeting.

It is understood that we meet on Thursday to discuss and put to the vote the conclusions which by then will have been printed in three languages. (*Approval.*)

Meeting held on 14 July 1910 (morning).

The President. (In French.) — We resume the discussion of question XVI : " Perishable goods."

Mr. Bloch will now address the meeting and read out the new proposed conclusions which he has drawn up.

Mr. Bloch, *reporter.* (In French.) — Gentlemen, the conclusions which I have the honour of bringing before you differ appreciably from those I have previously proposed. I have modified the latter to some extent, taking into consideration the remarks made during our last meeting, in particular by our German colleagues.

This is the new draft :

" The Congress records the great and general increase in the perishable-goods traffic, which is largely due to the special care which all railways devote to these very delicate goods.

" The discussion on this question led to the following conclusions :

" 1° Although carriage rates can eventually appreciably influence the traffic in cheaper perishable goods chiefly intended for popular consumption, yet as regards the more expensive classes, and particularly those of international commerce, the development of the traffic depends chiefly on the care taken to ensure that such goods arrive at their destination in the best possible condition. The railways could eventually give guarantees concerning this care under strictly-defined conditions and within strictly-defined limits.

" 2° A very important part of this care is however a matter for the producers, who should deliver their produce to the railways in the best possible condition as regards selection, preparation, condition, etc.; in this connection it may be useful for railway administrations to disseminate among producers information regarding the kinds of fruit in demand at the different markets, the best methods of preparation, packing, etc.

" 3° As regards the acceleration of consignments, it is desirable that appropriate rates or special rules should be inserted in the regulations of international conventions, so as to give consignors the option of choosing the routes giving them the quickest transit rather than the shorter routes, the consignments being charged at the rates fixed for the routes asked for.

" 4° Although transport with refrigeration or with special ventilation or with heating can be undertaken successfully by railway administrations in very large countries, such as the United States of America or Russia (including Siberia), yet conditions are far from being the same in the case of States of much

*

smaller area, such as those in Europe, for instance.

" In the case of transport in the interior of these countries, on account of the short distance and the quickness of transit, the use of these improved methods, even though it can always be recommended, has not, to anything like the same extent, the same character of necessity.

" Their use appears to be greater in the case of international traffic, generally over greater distances; and it is desirable that the administrations of the European railways should agree to common regulations in order to give such shipments in refrigerator vans all the facilities compatible with the requirements of their services.

" Moreover, owing to the very variable and special attention these shipments require during their whole transit, and owing to the participation of a number of administrations, it appears probable, at least in international traffic, that the operation of refrigerator vans would be managed under better conditions by private persons, working for this purpose by agreement with the various administrations cercerned.

" 5° On account of the difficulties caused by the return of empties, it would be of interest, both to the railways and to the future of the traffic, to promote the development of the custom of using packages which are not returned, known as " *non-returnable empties.*"

" On the other hand, it seems advisable to specify in the tariffs the conditions which packages in general must satisfy, so as to protect the goods as far as possible against thefts and the normal risks of carriage.

" 6° In order to prevent or diminish difficulties with consignees, resulting from waste ascertained on delivery in the case of goods specially liable to such waste, it would be desirable to supplement the summary rules of article 32 of the Berne convention and of paragraph 8 of the executory provisions, by more complete directions suited to the nature and the conditions of this particular traffic. »

Mr. Pichler von Deeben. (In German.) — It was only immediately before the meeting that the new proposed conclusions were distributed; there are six conclusions, all very important, and requiring careful consideration. It is hardly possible for me, and the same no doubt applies to other members, to check the agreement of the German text with the French text, and above all to grasp the full bearing of those conclusions. I feel sure that an hour or half an hour would suffice for this examination and I accordingly request you to give us the time necessary to form our opinions.

The President. (In French.) — We have before us a motion for adjournment. I must remark that the text of the conclusions just handed to you was sent to the printers the day before yesterday and we certainly hoped it would appear in the *Journal* published yesterday morning.

But finding this was not the case, we had off-prints made which were placed in the boxes. As our German colleagues think that they have not had time to grasp the full bearing of the new proposed conclusions, I think it would be advisable, in their interest, to adjourn the meeting for one hour.

Mr. Pichler von Deeben. (In German.) —

That time is long enough for us; I wish to thank the President, in the name of my colleagues as well as in my own, for kindly granting our request.

Mr. Elsner. (In German.) — In my opinion, the proposed conclusions which have just been distributed give rise to many objections, both as regards form and contents. I will mention the last paragraph, which is particularly important. It is a question of expressing the wish that paragraph 32 of the Berne Convention, which corresponds to the prescriptions of the codes of commerce of most of the countries belonging to the convention, and to their home regulations, should be modified. I therefore here declare, that I intend later on to bring forward again the proposal I made Monday last, of retaining the conclusions again in Mr. Bloch's printed report, with the amendment I proposed at the last meeting.

In my opinion, if we start the examination of new projects, it will take several days before we are finished, so important do these conclusions seem to me as to contents, and so difficult as to form.

The President. (In French.) — Is the meeting of opinion that it should adjourn for an hour? (*Yes, yes.*)

— The meeting is adjourned and will meet again at 11 a. m.

The President. (In French.) — Gentlemen, our German colleagues have not yet attended the meeting, but as Colonel Haines wishes to make a communication to the meeting, I propose that he should be heard at once. (*Approval.*)

Colonel Haines, United States Government. — I desire to express my thanks for this opportunity to offer some remarks as to the transportation of perishable products; and I shall address myself principally to the railway administrations of Continental Europe.

The official positions which I have occupied in the United States enabled me to gain much experience in this matter and, during a residence for several years on the Riviera, I have observed with surprise the apparent lack of interest in the development of traffic of this character in a region whose products are so well suited for it. Yet the railway administrations of France and of Italy, of Switzerland and of Germany, should draw substantial benefits from such traffic; for I believe it to be possible by cooperation among them to arrive at results similar to those that have been realized in the United States, where the revenue from the traffic in perishable products now amounts to many millions of dollars.

The report of Mr. Culp, whose competence in this matter is generally recognized with us, is replete with valuable information. I will refer to two of his principal conclusions :

1° The thorough expulsion of all heat from highly perishable animal and vegetable substances, before shipment;

2° The dissemination, among producers and handlers of all classes of perishables, of any and all suggestions of improvement in methods of preparation, packing, hours for delivery to carrier, and reasonable provisions against possible contingencies of transportation and delivery to consumer.

I admit that the European railway managements cannot make use of refrigerator

cars of the character that has been specially adapted to the long distances over which this traffic is conducted in the United States. The freight cars in the European service might however be better utilized in this traffic if provision were made for the reduction of the heat inherent in perishable products before their transmission. By this precaution, the development of the germs of fermentation is arrested and the traffic is made more remunerative to the producers and to the railway lines.

In the United States, this service is performed by private enterprises, which employ their own plant in refrigerator cars and in cold storage depositories.

In the ordinary refrigerator car service, the packages of perishable products are loaded into the cars with all their inherent head and moisture. Upon the reduction of temperature in the closed cars, the moisture which contains the germs of fermentation become congealed and are deposited upon the surfaces of the food products, to be revived into activity when they are again exposed to the external atmosphere. Under the preparatory or " pre-cooling " method, the germ-laden moisture is expelled from the closed car before its departure, and its contents remain in a dry and sterilized condition until the car is opened at destination. Not only are the perishable products delivered in a more marketable condition but much less ice is required in transit.

I would impress upon the continental managers here present the value of this traffic in perishable products to the railways of the United States; a value so great that lines have been constructed especially to provide facilities for its development in regions well situated as to soil and climate for such industries. The perishable products of the State of California are shipped in train-loads across the continent to the North Atlantic coast. Along the east coast of the peninsula of Florida there is a strip of land lying between extensive swamps and the sea, nowhere more than ten miles in breadth, which was but thirty years ago almost uninhabited. Now it is traversed for over four hundred miles by a railway line, whose principal traffic is in perishable products. From eighty miles of this line, in 1909, there were shipped about 2,000,000 packages of perishables valued at $2,500,000. I mention this particular instance for the reason that it may be compared in some respects with a like distance along the French and Italian Riviera. If similar results could be obtained in that region, profitable occupation could be offered to an industrious agricultural population, who are now expatriating themselves to seek subsistance elsewhere.

The success that has followed upon the introduction of improved methods for protecting perishable products from decay in transit, has cheapened the cost of such commodities in the northern cities of the United States to such an extent that they are now brought within prices which invite their consumption by the masses, with a corresponding extension of their profitable production. In this respect, we may also compare a similar traffic from the Riviera to Central and Northern Europe; a traffic which is specially favoured by the considerable reduction in the average winter temperature that accompanies the transit to these regions beyond the Alps.

I will conclude my remarks by expressing the hope that the railway administrations of Continental Europe will further the amelioration of the agricultural population along the Riviera by such co-operation with the producers of perishable products in that region as will develop this traffic to the extent which has resulted in the United States from similar co-operation. I take this opportunity also to express the interest which I feel in any measures that may serve to increase the prosperity of the European railways. (*Applause.*)

The President. (In French.) — As our German colleagues have finished their meeting, we will resume the discussion of the conclusions.

According to what Mr. Bloch has just said, our German colleagues agree to accept the proposed conclusions he has read out, subject to some modifications.

Mr. Bloch, *reporter.* (In French.) — I will give you in succession the different modifications which our colleagues propose to make in the conclusions which have been brought before you.

As regards conclusion 1, instead of saying :

" The railways could eventually give guarantees concerning this care under strictly-defined conditions and within strictly-defined limits"

we are going to say :

" It may be advisable from this latter point of view, that railways should give guarantees under strictly-defined conditions and within strictly-defined limits."

— The conclusion as amended is adopted.

Mr. Bloch. (In French.) — There is no amendment to conclusion 2.

The President. (In French.) — I accordingly declare it adopted.

Mr. Bloch. (In French.) — In conclusion 3, our German colleagues wish to strike out the words " than by the shorter routes ".

It seems to me that we can give them this satisfaction. (*Approval.*)

— The conclusion as amended is adopted.

Mr. Bloch. (In French.) — Conclusion 4 should be divided into two parts. This is how we propose to word conclusion 4-*a* :

" Although transport with refrigeration, or with special ventilation, or with heating, can be undertaken successfully by railway administrations in very large countries, such as the United States of America or Russia (including Siberia), yet conditions are far from being the same in most of the smaller countries, such as those in Europe.

" In the case of transport in the interior of these countries, on account of the short distance and the quickness of transit, the use of these improved methods, even though it can always be recommended, has not, to anything like the same extent, the same character of necessity. "

Littera *b* comes next, and runs as follows :

" In the case of international transport, it is desirable that the administrations of the European railways should agree to common regulations in order to give such shipments in refrigerator cars all the faci-

lities compatible with the requirements of their services.

" Moreover, owing to the very variable and special attention these shipments require during their whole transit, and owing to the participation of a number of administrations, it appears probable, at least in international traffic, that the operation of refrigerator vans would be managed under better conditions by private undertakings, working for this purpose by agreement with the various administrations concerned."

— Conclusion 4 as amended is adopted.

Mr. Bloch. (In French.) — No amendment to conclusion 5 is proposed by our German colleagues.

The President. (In French.) — I accordingly declare it adopted.

Mr. Bloch. (In French.) — Finally, we have agreed to draw up conclusion 6 in the following terms :

" In order to prevent or diminish difficulties with consignees, resulting from waste ascertained on delivery, in the case of goods specially liable to such waste, it is desirable to supplement, as regards the proportion of waste allowable, the rules in the international agreements. "

— Adopted.

The President. (In French.) — We have thus successively adopted the different conclusions concerning question XVI.

These conclusions will be submitted to the general meeting.

Gentlemen, we have completed our labours. Before closing the meeting, I wish to thank you for your attention and for the information you have given during the discussions. I also wish to thank the secretary-reporters and especially Mr. Etienne who is not only member of the organizing committee but spontaneously offered to join the bureau of the 4th section in order to perform the ungrateful task of acting as translator. (*Applause.*)

Mr. Timonoff. (In French.) — Gentlemen, it was been our good fortune to have as our president an eminent man who was able to fulfil his task with remarkable tact and courtesy, and I accordingly propose that the section should express to him our warmest thanks.

— This proposition was adopted with applause.

DISCUSSION AT THE GENERAL MEETING

Meeting held on 16 July 1910 (morning).

MR. P. WEISSENBACH, PRESIDENT, IN THE CHAIR.

GENERAL SECRETARY : MR. L. WEISSENBRUCH.

FIRST ASSISTANT GENERAL SECRETARY : MR. MÜRSET.

SECOND ASSISTANT GENERAL SECRETARY : DR. A. BONZON.

Mr. Bloch, *principal secretary of the 4th section*, read the

Report of the 4th section.

(See *Journal quotidien de la session*, No. 11, p. 10.)

" Mr. CULP described the main features of his report; he showed that the railways in the United States, which had to convey perishables over very great distances, up to 5,150 kilometres (3,200 miles), were compelled by the American laws to apply the most improved methods for bringing such produce to the points of destination in as nearly perfect condition as possible.

" The different countries to which he had sent his list of questions had to meet very different requirements, and consequently, needed such improved methods to very varying degrees.

" In the United States, there was at the time being a tendency to eliminate or at least reduce the refrigeration service on the road, by applying more and more improved methods, either by precooling the loaded cars, or by simple cooling, either by the vacuum process and by drawing in cold air, or by driving out the warm air by a reverse process.

" The reporter then read out his conclusions.

" Mr. BLOCH then gave a summary of his report. After a short description of the situation and the tendencies of the European market, he considered in succession the tariffs applied in the different countries and the conditions of liability which many of these tariffs involved. He then described the organization and the speed of these transports in different countries, and entered upon the difficult question of the rolling stock, particularly of the refrigeration stock, which was still in a very elementary state in the European countries. He noted the varying tendencies of the different laws and customs in connection

with the settlement of claims and the questions of packing; he then mentioned the propaganda of some of the railway administrations for the development of production, and finally submitted his conclusions in which those of Mr. Culp had been taken into consideration.

" During the discussion, Mr. WIEDEMANN (*secretary-reporter*) in the first place disputed that in countries where there were both State railways and privately-owned railways, there was any difference between the rules applied in the one case and in the other. He noted that in Switzerland the law had not been modified since the State purchase. Dr. ELSNER (*German government*) remarked that the home railway regulations in Germany were not more restrictive than those of the Berne International Convention. Mr. LÜTTKE (*Prussian State Railway*) added that the reductions of the tariffs could have a useful influence on the traffic of cheaper perishable goods chiefly intended for the poorer classes.

" Mr. PICHLER VON DEEBEN (*Austrian State Railway*) confirmed the statements made by the representatives of the German railways, as the conditions of the traffic and the regulations were approximately the same in Austria.

" Mr. SILVA-FREIRE (*Brazilian government*) drew attention to the traffic in tropical fruit, especially bananas.

" Mr. TIMONOFF (*Russian government*) drew attention to the development of the fruit and vegetable traffic in Russia, due to improvements in the tariffs and in the regulations of railways.

" The discussion was closed by the reporter's reply; among other things he stated that he had never expressed the opinion that different rules were applied in any country to State railways and to privately-owned railways, and that the advantage of reductions in the tariffs for cheaper produce also seemed apparent to him.

" Finally, the 4th section unanimously adopted the reporter's conclusions, amended in accordance with the import of the remarks made during the discussion, the following being the text proposed."

The President. — The following are the

CONCLUSIONS.

" The Congress records the great and
" general increase in the perishable-goods
" traffic, which is largely due to the special
" care which all railways devote to these
" very delicate goods.

" The discussion on this question led to
" the following conclusions :

" 1° Although carriage rates can even-
" tually appreciably influence the traffic
" in cheaper perishable goods chiefly
" intended for popular consumption, yet
" as regards the more expensive classes,
" and particularly those of international
" commerce, the development of the traf-
" fic depends chiefly on the care taken to
" ensure that such goods arrive at their
" destination in the best possible condi-
" tion. It may be advisable from this
" latter point of view, that railways should
" give guarantees under strictly-defined
" conditions and within strictly-defined
" limits.

" 2° A very important part of this care
" is however a matter for the producers,

" who should deliver their produce to the " railways in the best possible condition " as regards selection, preparation, con- " dition, etc.; in this connection it may " be useful for railway administrations to " disseminate among producers informa- " tion regarding the kinds of fruit in " demand at the different markets, the best " methods of preparation, packing, etc.

" 3° As regards the acceleration of con- " signments, it is desirable that appro- " priate rates or special rules should be " inserted in the regulations of interna- " tional conventions, so as to give con- " signors the option of choosing the " routes giving them the quickest transit, " the consignments being charged at the " rates fixed for the routes asked for.

" 4° *a*) Although transport with refri- " geration or with special ventilation or " with heating can be undertaken suc- " cessfully by railway administrations in " very large countries, such as the United " States of America or Russia (including " Siberia), yet conditions are far from " being the same in most of the smaller " countries, such as those in Europe.

" In the case of transport in the interior " of these countries, on account of the " short distance and the quickness of " transit, the use of these improved me- " thods, even though it can always be " recommended, has not, to anything " like the same extent, the same character " of necessity.

" *b*) In the case of international trans- " port, it is desirable that the administra- " tions of the European railways should " agree to common regulations in order " to give such shipments in refrigerator " cars all the facilities compatible with " the requirements of their services.

" Moreover, owing to the very variable " and special attention these shipments " require during their whole transit, and " owing to the participation of a number " of administrations, it appears probable, " at least in international traffic, that the " operation of refrigerator vans would be " managed under better conditions by " private undertakings, working for this " purpose by agreement with the various " administrations concerned.

" 5° On account of the difficulties caused " by the return of empties, it would be " of interest, both to the railways and to " the future of the traffic, to promote the " development of the custom of using " packages which are not returned, known " as " *non-returnable emptics.*"

" On the other hand, it seems advisable " to specify in the tariffs the conditions " which packages in general must satisfy, " so as to protect the goods as far as pos- " sible against thefts and the normal risks " of carriage.

" 6° In order to prevent or diminish diffi- " culties with consignees, resulting from " waste ascertained on delivery, in the case " of goods specially liable to such waste, " it is desirable to supplement, as regards " the proportion of waste allowable, the " rules in the international agreements."

— These conclusions were confirmed by the general meeting.

APPENDIX

[625 .244 & 656 .235.7]

ADDENDA TO REPORT N° 1

(Countries using the English language)

By J. M. CULP,
VICE-PRESIDENT, SOUTHERN RAILWAY.

CHAPTER I.

Additional matter regarding Kosher meat : Vegetables requiring refrigeration; Description of ice tanks in beef car; Results from pre-cooling furnished by Roy.

Fresh meats, products of abattoir, etc.

A fact interesting to Jewish patrons is the careful attention paid, not only by Packers but by Transportation Lines, to the preparation and shipment of meat bearing the approval of the duly constituted authorities of the Jewish Religion. After this meat receives the stamp of the Rabbi, it is not differently handled in any material sense from other classes of fresh meat, but to comply with requirements, the meat must be delivered to consumer within seventy-two hours of its slaughtering. This means it cannot be retained in the coolers at Packing Houses for the full time required for complete chilling, dependent always, of course, upon the estimated schedule to the consuming market.

The chilling of the meat is therefore continued during transit and necessitates closer attention to icing of cars, both at packing houses and in transit, than is the case where meat is loaded in a perfectly chilled condition.

While meat for ordinary American trade, which has been chilled by ordinary

processes, moves into market within sixty days of its slaughtering, it sometimes happens that the meat is held as long as ninety days and still delivered in edible condition.

—

Consideration should be given to the efficiency in the preparation and transportation of fresh meat of pre-cooling systems now being employed by carriers in handling of fruits and vegetables. It is claimed for one of these systems, namely, the *Intermittent Vacuum or Sprague System* (Southern Pacific), that meat may be cooled down to the required temperature of 30 to 34° in two hours, as against estimated requirement of forty-eight hours under the present plans. Our investigations do not develop that this experiment has actually been made.

—

Descriptions furnished of cars for handling fresh beef and other meats under ice, allude to a system of ice tanks over a drip pan connected by a pipe and trap with the outside, permitting the outflow of the drippings. This description may be amplified by stating that the drippings which flow into the pan under the ice tanks come from moisture precipitated upon the side of the tanks, usually in the shape of frost. The overflow of the contents of the tanks takes place through a tube arranged inside of one of the four tanks situated in the ends of the beef car. These four tanks are connected by a small pipe, and as the liquid brine is formed in each tank by the melting of ice, it rises to the same level in each of the four tanks. The overflow of this brine escapes through the tube just alluded to, which discharges through the same outlet in the floor of the car as provided for the escape of the drippings from the outside of the tanks. A valve is provided at the bottom of the tank containing the overflow tubes to permit the complete emptying of all the tanks.

Fruits and vegetables.

Cantaloupes are usually shipped under ordinary icing, the same as provided for other highly perishable fruits and vegetables at a temperature of about 45 to 50°.

We find, on investigation, that there is no vegetable in America which is invariably shipped under refrigeration, but those most commonly requiring refrigeration are : lettuce, celery, spinach, asparagus and radishes. All vegetables except ordinary perishables, are shipped under refrigeration at times. The practice of one of the largest carriers of vegetables indicates that about 60 per cent of the vegetables move under ventilation at all times; about 40 per cent will require more or less ventilation.

The Bohn Collapsible Ice Tank applied to Refrigerator Cars.

A very interesting improvement in transportation appliances which has come to our attention, is the Bohn Refrigerator Car, equipped with collapsible ice tanks, the essential feature of which is the movable partition, or wall of the ice tank inside the car. When this wall is in position (fig. 1) to receive ice in the bunkers, it affords a receptacle for the ice, not essentially different from the stationary ice

tanks in the ordinary refrigerator car for fruit and vegetable movement, and that is a zinc lined compartment (expanded metal) with grates at the bottom, underlaid by a drip pan with the usual discharge pipe for the overflow. The movable partition or wall described above, can be lifted up (fig. 2) and fastened to the top of the car (fig. 3); and the grates are also folded up, and there is added to the cubic contents of the car for the loading of ordinary fruit not less than 11 to 12 per cent. This device has already been adopted by the Union Pacific & Southern Pacific Lines in the construction of about twelve hundred Pacific Fruit Express refrigerator cars. Chief Freight Traffic Officials of those lines are enthusiastic over the results. The addition to the initial cost of the equipment is about 10 per cent. The increase in the dead weight is 1,000 lb. but the increased loading capacity for the character of freight transported in refrigerator cars, completely offsets the additional cost and the increased dead weight. Furthermore, there is an advantage from readiness of cleaning, the car with the ordinary ice bunker requiring considerable effort and time to effect thorough cleansing, whereas with the collapsible tank, permitting access to the remotest corner or crevice of the car, a thorough cleansing is possible.

Pre-cooling.

Our attention was drawn to results of experiments on pre-cooling as now conducted by Pacific Fruit Express Management in California.

In the case of vegetables, experience has proved that the pre-cooling of celery added to its value in Eastern markets about 50 dollars per car, as against ordinary icing; pre-cooling of cauliflower added 300 dollars per car.

Shipments of strawberries precooled and shipped under initial icing only, were transported 1,000 miles to Salt Lake City and kept in good condition five days after arrival exposed to the air.

A comparison of shipments of celery, one pre-cooled under initial icing, the other under standard icing presented the following results :

At the end of the second week celery shipped under standard icing showed some signs of deterioration, at the end of the third week the shipment had to be sold immediately to prevent entire loss; on the other hand, at the same time, the contents of the pre-cooled car showed absolutely perfect condition and sold for 1 dollar per crate more than the shipment under standard icing.

The Intermittent Vacuum principle serves to withdraw impurities, including the inherent germs of decay, while it supplies the chilling effect. The elimination of impurities is shown by the intensely foul air observable at the discharge pipes during the operation of the suction or vacuum process.

The Intermittent Vacuum principle contemplates the application of a blast of cold air for a period of five minutes followed by the suction or withdrawal of air from the contents of the car for a period of three seconds. It is during this period of suction that the bad odors are observable. No deterioration in texture or taste has been observable as the result of the expulsion of the impurities by the suction process. On the contrary, fruit can be allowed to remain on trees to point of

full maturity before gathering. This possible benefit has already been alluded to in the report.

Experience shows no loss in weight from the application of pre-cooling.

In the case of cabbage shipped under ordinary icing reaching destination in four or five days, the hatches were hard to hold down because of gases from deterioration and decay. A pre-cooled car for the same distance showed no impurities or gases.

A shipment of cantaloupes from an outlying district of Los Angeles was pre-cooled before shipment to 38°. It was handled into Los Angeles, held there a period of three days, at the end of which time fifty boxes of oranges were inserted in the car; the car closed up and held one day. When the car was opened at the end of the fourth day the oranges were found to be cool. The major part of the load of cantaloupes was taken out and shipped to Goldfield, Nevada, a distance of 531 miles, and exposed on the stands of fruit sellers for seven days, when they were found to be perfectly sound and in cool condition.

The appliances lowering the temperature of pre-cooled cars are regulated by a thermostat insuring the production of the temperature desired.

Advocates of pre-cooling claim no initial icing will be required for distances calling for three and a half or four days' movement. They further claim that intermediate icing may be entirely done away with. This latter statement is borne out in a case of shipment of oranges from Los Angeles to New York, which moved under initial icing only, and it was found that the temperature at destination had risen only 2°.

Extracts from annual reports of chief of Bureau of Plant Industry, 1901-1908, United States Department of Agriculture.

During the year 1904, an investigation of the causes of the decay and softening of perishable fruits, like the peach, during transportation to market was begun. It has been discovered that a large part of the difficulty is due to bad handling or improper condition of the fruit before it is placed in the refrigerator car. Through the co-operation of the Hale Georgia Orchard Company at Fort Valley, Ga., a number of carloads of peaches were forwarded to northern markets and an accurate record of the condition of the fruit in different parts of the cars was made. The fruit was packed in the six-basket carriers commonly used for peaches in that State, the carriers being loaded five tiers high in the refrigerator cars in the usual way. It was found that under the conditions experienced at Fort Valley, the fruit often has a temperature of 90 to 95° Fahr. when loaded. Under present practice, the ice in the refrigator car is expected to do the initial cooling as well as to maintain the desired low temperature afterwards. Early, tender-fleshed varieties, like Carman and Waddell, and firmer kinds, like Belle, Thurber, and Elberta, were included in these tests. The early, tender-fleshed varieties often showed from 5 to 20 per cent of soft and decayed fruit in the two upper tiers in the car, while the three bottom tiers arrived in the northern markets in sound condition. This unequal condition on arrival is unquestionably due to the more rapid cooling of the fruit in the bottom of the car, and emphasizes the conclusion previously reached in these investigations, that quick cooling after picking is a fundamental requirment in successful cold-storage operations. To test the accuracy of this point,

Intermittent Vacuum Faget Precooling System Co.

a temporary cooling plant, consisting of two refrigerator cars, was devised in an ordhard of the Hale Company. In each of these, half a carload of fruit was placed for cooling prior to loading in cars for shipment. These coolers were refrigerated by using ice and salt in their ice bunkers, the temperature of the fruit being in this way reduced to about 40° Fahr. in about twenty four hours. Fruit loaded at at the same time into refrigerator cars with ordinary icing did not reach a temperature of 40 to 50° Fahr. within three to five days. After the fruit in the coolers had reached a temperature of about 40° Fahr., it was transferred to a refrigerator car and sent North under regular icing. *Nine* carloads of *peaches*, or about 6,000 packages, were forwarded under these conditions, with the result that practically all of the fruit arrived in New York and other northern markets in sound condition, with no loss even in the upper tiers of carriers. Recording thermometers showed that under these conditions the ordinary icing of the car maintened in transit the low initial temperature of the fruit. Peaches handled in this way can be left on the trees until much riper, and therefore until they possess finer flavor and higher color than is possible with ordinary shipments, and still will arrive at destination in perfectly sound condition. After removal from the car, such fruit remains sound longer than the prematurely picked fruit shipped under ordinary icing.

Milk shipments.

We find that small shipments of milk are being made from time to time from Chicago to New Orleans, a distance of 921 miles, the movement taking place under ordinary refrigeration.

CHAPTER II.

Pre-cooling, as developed and practiced by the Southern Pacific Company, in California.

This company uses what is known as the " Intermittent ", or Sprague-Edson system, and has spent considerable time and money in developing this. In general, the process of pre-cooling, is to rapidly refrigerate fruit, vegetables, melons and other perishable goods, at the point of shipment, in the cars in which they are to be transported. There are several advantages in this process, of which the most important is that the fruit, etc., so pre-cooled may be allowed to become thoroughly ripe before shipment; and the transportation of any fruit or vegetable, however delicate it may be, for long distances, becomes feasible and practicable, so that at the point to which it is consigned it will be received in practically the same condition as that in which it was shipped. The well-known method of shipping fruit in ice-cooled cars is, of course, a vast improvement on no refrigeration at all, but it is open to the very great objection that the temperature of the

car is so gradually reduced by icing that it takes two or three days before the entire contents of the car are cooled down to a point at which decay is arrested, for which reason it is necessary to ship perishable goods in a more or less unripe condition to allow for further ripening in transit. It is evident, therefore, that any process, which can greatly expedite the initial refrigeration of a car will permit of the shipment of fruits, melons, etc., in just so much more perfect condition as regards ripeness. This is precisely what pre-cooling does; that is to say, that by the use of this method, a carload of fruit may be so quickly brought below the point at which decay is arrested, that the contents may be absolutely ripe when shipped, and may be delivered to the consignee in practically the condition in which they were picked.

Besides the element of temperature, the emanations from the fruit itself are aids to decay and it has been found to be of great advantage to be able, not only to lower the temperature of the contents of the car, but to withdraw therefrom the heated air given off by the contents, and supercharged with foul gases and emanations; so that the " Intermittent " system in use by the Southern Pacific Company is devised to accomplish both these results; namely, refrigeration and purification. The apparatus for this purpose consists in forcing air through a false door, or other aperture, at, or near the middle of a car, and distributing this air through the boxes of fruit packed in the car, by means of suitable deflectors and baffles. The cool air passes into the car in a continuous stream, and is withdrawn from the end hatches by means of temporary connections. At suitable intervals the inlet is closed for a brief time and an exhaust maintained in the outlet pipes, so that a partial vacuum occurs in the car. During this part of the process, the exhaust air is discharged into the open air, or vasted. The inlet is then opened and the exhaust into the outer air closed, so that a circulation of cold air through the car is resumed. The cold air after circulating through the car, is passed by suitable fans over and through a coil of cooling pipes so as to condense moisture or essential oils emanating from the fruit, or rather, that small portion of these which is left in the air after the vacuum process. The amount of vacuum, the frequency of its application, and the length of time during which it is maintained, should vary with the kind and condition of fruit, vegetable, etc.

To sum up, by this process not only are the contents of the car refrigerated, but they are also surrounded by sweet, clean air, sterilized by refrigeration. After pre-cooling, the cars are fully iced as usual, so as to maintain a low average temperature during shipment. This preserves the delicate flavor of fruits, berries, and vegetables shipped for long distances, and they arrive in a condition not heretofore possible under ordinary refrigerating methods; and there is evidence to show that the contents keep better when exposed for sale than fruit which has been shipped in the ordinary way.

In reference to description of Plant at Colton, would say that the Plant was originally installed for a 200 ton ice making Plant. However, with recent improvements we have been able to bring

this up to approximately 300 ton per day of twenty-four hours; this while not precooling, as the precooling itself takes quite some little power and of course, reduces the ice making capacity in proportion.

The Boiler Plant is of 1,000 horsepower capacity, divided into three units, two of which are in constant use and one in reserve.

The precooling portion of the Plant consists of two precooling sheds, each being of sufficient dimensions to permit of the precooling of twenty cars at a time, or a total of forty cars.

The double shed being for the purpose of facilitating the handling of the connections to cars, as immediately after one set has been precooled, the other having been attached no delay occurs, or in other words, the precooling could be continuous, and would therefore permit, with the present size of Plant, of precooling between one hundred and sixty and one hundred and eighty cars per day of oranges and of approximately four hundred cars of vegetables, this reducing the temperature from 80 to 40° Fahr., with an actual running time on each set of (20) cars of about two hours and one-half to three hours. The total amount of air circulated per minute when handling (20) cars is approximately 200,000 cubic feet, this is a velocity varying from 6,000 to 8,000 feet per minute.

The inlet and outlet connections to cars being so proportioned that immediately upon entrance of air into body the pressure drops. In other words, we retain the quantity of air and the velocity and reduce the pressure in the car to that practically of the atmosphere. This so as to prevent either the ingress of hot air and the egress of cold air, this to minimize the refrigeration losses as much as possible.

To further carry out this idea each precooling station is divided into two units, each unit in itself being divided into two parts, thereby enabling us to handle any number of cars from one up to the maximum capacity of the plant with practically the same efficiency.

The intermittent Vacuum System has now been arranged so as to operate entirely automatically. During the first hour, the valves being opened every five minutes and remaining open for a very short period, this sufficiently long to discharge the fruit emanations and to replace it with fresh cold air; during the second hour this operation taking place every ten minutes, and so on throughout the entire precooling period according to conditions.

The figure 4 shows the delivery and exhaust system, direction arrows showing movement of air currents.

For cars with different sizes of openings, there has been designed an independent plug into which a regular plug attached to flexible connection is inserted, which permits the meeting of almost all conditions. The joint in the plugs on the outlet as well as the false door in the inlet side being arranged with inflated tubes and canvas so as to make a practically tight joint with car body. The connections themselves are made up of several layers of rubber and canvas in " accordion " fashion, with an annular air space and which, while being very flexible and taking care of almost every possible condition, also prevents refrigerating losses; in fact, it has been worked very successfully. Each inlet and each outlet are also constructed with

a specially designed valve so that any car can be cut out (without interference to the others) and which is done when three or four cars are precooled.

As to any dead portions of car, it is stated that the quantity of air and the velocity which we use, and which is the only method by which we could use such low temperatures and precool in a length of time satisfactory to the Transportation Department, entirely prevents any possibility of their being a portion of car body in which there is not a rapid circulation.

There are two sections of the Coil Box where the air is cooled, both containing Ammonia Coils through which the air from the Fans is blown, the air first going into the upper section from the Fan, thence down into the lower section and through the series of Valves and Connections into the Inlet Duct marked « *Cold Air to Cars* », thence through the Flexible Connections and False Doors into the car body and out from both ends at the top through the Flexible Connections into the Return Air Duct which is shown on one side (fig. 4) to better illustrate and from the Duct back into Fan again and so on, thereby forming a continuous circulation of cold air.

The arrangement of the Valves for operating Intermittent is shown on figure 5. The idea being that the apparatus being all worked through gearing and shafting operates simultaneously. That is, the Valve on Inlet Air Duct marked No. 2 and the Valve marked No. 1 would simultaneously close with the opening of Valve No. 3. The closing of Valve No. 2 prevents any cold air passing from Coil Box into the Cars and the Closing of Valve No. 1 prevents any air from the Fan being discharged into the Coil Box so that the Fan is simply drawing the air from the cars and discharging it through Valve No. 3 into the atmosphere, thereby producing a partial vacuum in the car bodies, as Valve No. 2, being closed tight, will not permit any air to enter through the Inlet Duct. In other words, the whole and entire apparatus is made so that when Valves No. 1 and No. 2 close, No. 3 opens, thereby stopping the current of cold air from entering the cars, the Fan then drawing the foul gases from the cars and blowing it into the atmosphere.

The method of operation being to make all the connections to the cars and then exhaust the air from the cars for the first few minutes, discharging this through Valve No. 3 into the atmosphere. The opening of Valves No. 1 and No. 2 and the closing of Valve No. 3, thereby blowing the air from the Fan through the coil-box in through the cars drawing this air into the Fan again and through the Coil Box and so on indefinitely. The automatic operation of the Valves takes place every five, ten or fifteen minutes according to the condition of fruit whereby the flow of air into cars is cut off and this vacuum process gone through and so continuously throughout the entire precooling period. These Valves automatically open and close thereby discharging a certain quantity of air into the atmosphere and replacing it with cold fresh air. In other words, the Intermittent Process is worked at the time given and this according to the condition of the fruit itself. The flexible connections

shown are worked on Swing Joints on the Outlet from cars so that they can be swung out of the way the moment car has been precooled and is ready for icing. The same thing being done with the False Door, where the cold air enters. The idea being to handle the cars as quickly and with as little labor as possible.

CHAPTER III.

Precooling as developed and practiced by the Atchison, Topeka & Santa Fe Railway, in California.

In addition to the Sprague or Intermittent Vacuum System of precooling, there has been developed since the preparation of the original report a system which may be called the Gay, invented by Mr. C. M. Gay, and described briefly as follows :

A fundamental feature of the Gay system of precooling is a rapidly driven current, or blast, of cold air, in the application of which to the space enclosed by the walls of the car the excess over normal atmospheric pressure in the delivery or blast duct is equalized by a corresponding deficit below normal atmospheric pressure in the exhaust or return duct. The balance thus effected occurs exactly at the center of the car, and, it is claimed, the penetrative efficiency of the blast is fully maintained, with minimum loss of refrigerating energy due to unavoidable leaks in the car.

This balance of pressure is preserved by a valve located in the partition between the blast duct and the exhaust duct at their common extremities, and operates automatically.

The blast and exhaust currents are created by fans; one situated at the entrance to the blast duct and delivering thereto cold air from the cooling room; the other situated at the end of the exhaust duct, drawing the air therefrom after it has performed its cooling function, and returning it to the cooler room to be re-cooled and again started on its circuit.

Another primary feature of this system is the large intake valve to permit replenishment of atmospheric contents of the system. This valve is situated in the outside wall at the extreme end of the exhaust duct and so adjusted by tension spring to automatically admit air from the outside, when the inside atmospheric pressure goes below that determined by the differentiating valve described in the foregoing paragraph.

This system has been adopted by the Atchison, Topeka & Santa Fe Railway in connection with an ice-making and precooling plant at San Bernardino, California, which was in course of construction when inspected by us. No photographs were available, but blue prints showing essential features are submitted (figs. 6 to 8).

The combined ice making and precooling plant of the Santa Fe Railroad at San Bernardino, California, is a reinforced concrete structure with a total length of

1,360 feet, or something over a quarter of a mile. The ice making capacity of the plant is 250 tons per day of can ice with a day and winter storage whose combined capacity is 30,000 tons. The power plant is equipped with three 350 horse-power Stirling boilers and two cross compound, duplex, Vilter, refrigerating machines each of 300 tons capacity. The ammonia condensing system is of double pipe type placed over a concrete reservoir 80 feet square and 10 feet deep. A water supply of about 500 gallons per minute is furnished from an artesian well whose flow is accelerated by air lift to the required amount. A large day storage, 120×142 feet, gives a capacity of 900 tons of ice when covered by one tier of 300 lb. blocks on end. The winter ice storage is divided into four rooms of something over 7,000 tons storage capacity for each room.

The precooler equipment (figs. 7 and 8) extends from the end of the winter storage and is equipped for handling thirty-two refrigerator cars at a setting. The main air ducts of the precooler are of concrete and form the support of the car icing platform. The precooling system has been installed by Mr Gay under his designs and patents.

The air is cooled by galvanized brine pipes located in coil chamber at the end of the winter storage. The brine used is taken from the ice tanks by electrically driven pumps sent through its refrigerating circuit and returned through a 200 ton double pipe brine cooler which together with the circulating pumps is located beneath the day storage. A double deck tunnel or passage-way of reinforced concrete extends through the winter storage from the precooler to the day storage where the tunnel continues as a single tunnel beneath the day storage to the double pipe cooler rooms.

All of the ice is handled by direct conveyor passing the day storage and through the upper section of the tunnel through the winter storage where it may be diverted to the storage rooms or carried on to the car icing dock as required. The lower compartment of the tunnel is used for the brine mains running to the winter storage and to the pre-cooler coil chambers.

The whole storage house is insulated with " Nonpareil " cork board, the floors being made of concrete covered with cork board and a finishing floor of asphalt. The roof is insulated with " Linofelt " and air spaces. As all the ice is handled through the central tunnel of the day and winter storage room there are no outside openings or exposures whatever.

The air circulation in the main precooler ducts is accomplished by eight No. 11 Sirocco fans with a combined capacity of 300,000 cubic feet of air per minute. The concrete main air ducts are internally insulated throughout with cork board and " Linofelt " and the main air ducts are themselves piped with 50,000 feet of $1\frac{1}{4}$ inches galvanized brine pipe.

Four of the Sirocco fans are used to exhaust from the upper main duct delivering the air to the coil chamber. The other four draw the air from the coil chamber and deliver to the lower or main pressure duct. Extending from these ducts the lateral air pipe connections are fitted with liquid sealed revolving joints in such a manner that connection can be made to a whole train of cars without uncoupling or spotting the cars and whether the cars are of uniform lengths or not.

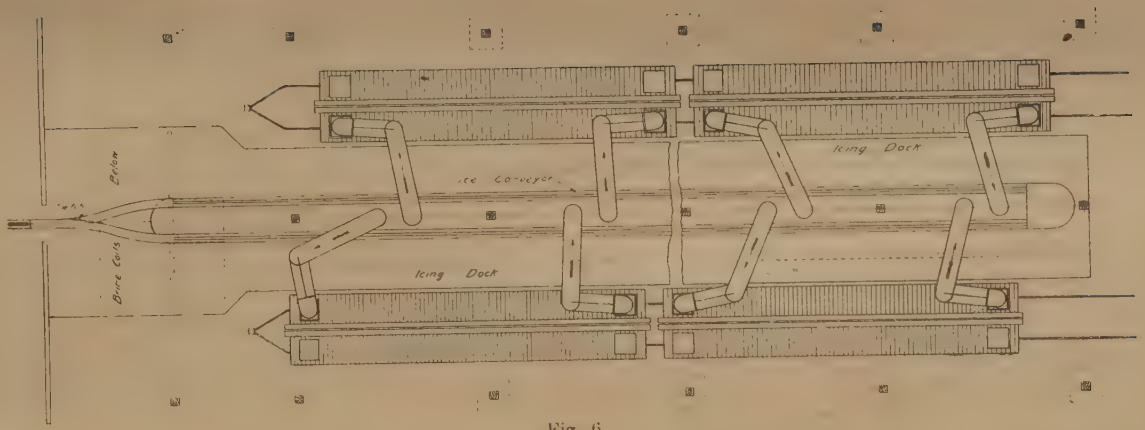

Fig. 6.

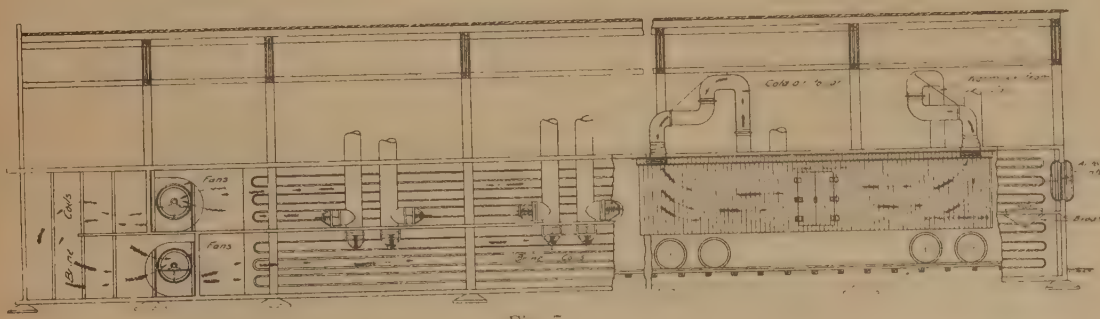

Fig. 7.

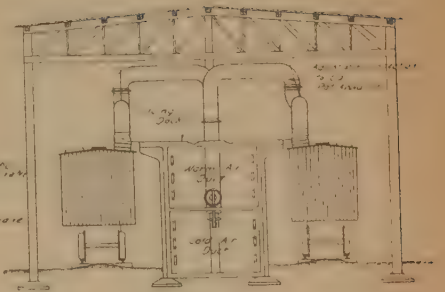

Fig. 8.

Figs. 6 to 8. — Gate City ice and precooling plant, San Bernardino, Cal. — Gay patent precooling system.

At the extremity of the main air ducts furthest from the coil chamber, a large automatic valve connects the pressure and vacuum ducts and by regulation of the tension at which this valve is held closed the pressure at which the air is delivered to the cars and the suction at which it is withdrawn from them is regulated at will.

At the extreme outer end of the main suction duct is also located an automatic intake valve for replacing any air lost from the system by blowing the warm air from the cars. This valve is regulated at a differential pressure as between the external atmosphere and the slight vacuum held in the low pressure duct so that when the total amount of air being circulated is reduced, this valve immediately opens to supply such deficiency at the beginning of the refrigerating circuit. Such air must then pass the full length of the main refrigerating suction duct through the coil chamber and be delivered back to the high pressure duct before it can enter the cars. Each lateral pipe has a valve opening into both the high pressure and low pressure main ducts. These valves in the respective ducts are controlled by the same lever or crank thus securing the effects of cross connection and reversal of air current without cross connecting the laterals. To summarize the novel and striking features of this system as installed at the San Bernardino plant we have :

The combination of main air ducts and car-icing platform and ice-carrying tracks all in one structure.

The refrigeration of the main ducts from the coil chamber to their extremities keeping the circulating air under refrigeration at all times except when passing through the short lateral connections extending to and from the car.

Liquid sealed revolving joints on lateral connections give universal horizontal adjustment in connecting to the cars.

Automatic by-pass valve at extremities of main air ducts capable of being regulated to secure any required differential pressure as between the high and low pressure main ducts.

Automatic intake at beginning of refrigerating circuit to insure the proper cooling of any outside air brought into the system during operation.

The prime object aimed at is to secure the circulation of a very large amount of air through a car without loss by forcing the cold air to the outside or drawing warm air in from the outside through the car itself.

Mr. Gay's experiments proved conclusively that all refrigerator cars are far from being tight. Experiments on a large number of cars showed that with a car closed as tightly as possible, an air pressure equivalent to $^1/_2$ inch of water would result in a loss of air through unseen openings of from 800 to 2,000 cubic feet per minute, and that an equivalent vacuum would produce practically the same result in the amount of air drawn in from the outside. Consequently, in order to perform the function of precooling in an efficient manner and without great loss of refrigerating capacity it was highly necessary that exactly as much air be withdrawn from the car as was being forced to it and that the system must be so balanced that the point of equalization between the pressure coming from the main pressure duct and the suction coming from the main return ducts, should be as nearly as possible in the center of the car.

To accomplish this, the two sets of fans were installed, the function of one being to blow from the cooling chamber directly into the main pressure ducts, and the function of the other being to withdraw the air from the vacuum duct with the same amount of differential below atmospheric pressure that is shown in the pressure duct above atmospheric pressure, thereby insuring the point of equalization as between the high and low pressure sides being maintained at practically the center of the car. So nicely can this be balanced that the side doors of a refrigerator car may be opened during the process of precooling without any blast of air being felt going out or coming into the car although 6,000 to 8,000 cubic feet, of cold air per minute is passing through the car.

It is the practice in refrigeration, to connect the pressure duct to the bunker openings first, opening the valve allowing the air pressure to drive out the warm air in the car, and as soon as the warm air has been expelled, to attach the return or suction connection at the opposite end of car and open the valve communicating with the main suction duct; thus completing the circuit of the air through the car. It is evident that in displacing the warm air in the car before connecting the suction duct, that an equivalent amount of air is withdrawn from the refrigerating system thereby lowering the pressure in both of the main ducts. The automatic intake valve is so regulated as to respond to the lowered pressure admitting an equivalent amount of outside air at the beginning of the refrigerating circuit. Were it not for the location of this valve providing for taking the air in at the beginning of the circuit, it would naturally come in at any place past the centre of the car towards the return side where the pressure would naturally be lowest. Such air coming in at this point in the car itself would naturally have the effect of nullifying the refrigerating effect of the air circulation and lowering the efficiency correspondingly, besides having a tendency to precipitate moisture in the wrong place instead of precipitating moisture on the cooling pipes in the main ducts and cooling chamber. Closing connection between the lateral air pipes and the car bunkers is effected by a bellows joint which preserves the entire area of the pipe under all adjustment.

The lateral pipes have an internal diameter of 22 inches.

The amount of air which can be circulated through each car is about 8,000 cubic feet per minute with thirty-two cars connected at once. The maximum amount allowed for cooling these cars is four hours, which together with the icing which is performed with the cars in the same position gives a total time of less than five hours per setting. This gives the San Bernardino plant a maximum precooling capacity of thirty-two cars every five hours.

In this plant provisions are made for complete metering of all brine used in precooling and for cooling the ice storage rooms, and with thermometers giving the temperature of the metered brine. Main air ducts and laterals are provided with barometric columns showing pressures at which air is circulated and returned and instruments are also provided for measuring the velocity of the air in both feed and return laterals giving opportunity for keeping a complete refrigeration record

on every car that is cooled. In addition to this long test, thermometers will be used extending to the center of boxes in car showing the temperature to which the fruit is cooled during the operation.

This means instruments provided to show : 1° air pressure by barometer; 2° the velocity of blast of air passing through car; 3° the temperature of the fruit in the car.

CHAPTER IV.

Description of Garland improved ventilated refrigerator car.

We have personally inspected improvements which have been made in the Garland Ventilating Device, resulting in a combination of ventilation, refrigeration and steam heating described as below and illustrated in figures 9 and 10.

The Garland refrigerator car. — This car is designed to protect shipments of fruits, vegetables and other perishable freight at all seasons of the year, the arrangement being to furnish ample refrigeration, ventilation, or heating as may be required.

The car is constructed with the usual ice tanks (figs. 9 and 10) at each end of the car with hatch openings, plugs and hatch covers. The drip pans are raised about 15 inches from the floor of the car and the ice grates are about 12 inches above the drip pans. Inside of each ice tank, in the center, and next to the end of the car is an air duct 10 inches square (inside) extending from the top of the pan to the floor of the car, opening at the bottom towards the body of the car.

At the upper end of the duct is a square opening through the end of the car. A padded hinged door is fitted to this opening on the outside of the car and over this door is a galvenized iron duct or air in-take which extends above the roof of the car, and at one side of the running board. On the upper end of this duct is a reversible hood which is ajusted to take in air when the car is running in either direction. This hood is placed in proper position at loading point and is not changed unless the car is turned while en route.

On the roof of the car near the center are placed two exhaust ventilators with square openings down into the car. At the underside of the openings are placed padded plugs which fit into the openings and are opened or closed by means of levers on the roof.

On the floor of the car is placed a slatted flooring which is divided into five sections, two sections at each end and a center section. The end sections are divided at the center and are hinged at each side permiting them to be raised up against the sides of the car. The center section is not hinged, but is held in place by the end sections when down.

There is a space of five inches between the regular floor and the slatted floor. In

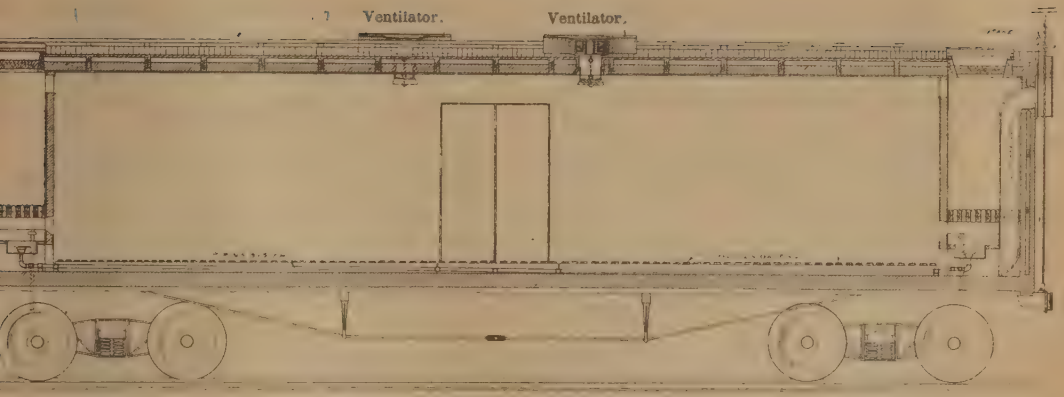

Fig. 9. — Longitudinal section of car.

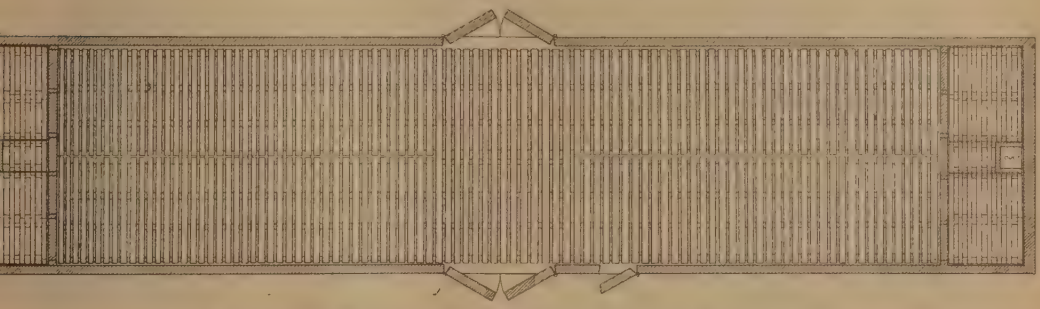

Fig. 10. — Floor plan, showing floor and ice racks in place.

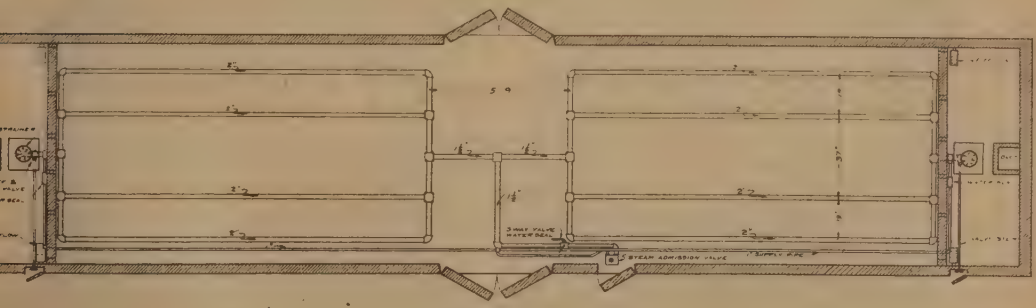

Fig. 11. — Floor plan, racks removed, showing piping system.

Figs. 9 to 11. — Garland system of refrigeration, ventilation and heating of refrigerator cars.

this space is placed iron piping (fig. 11) resting on the lower floor and arranged for heating and cooling. The vapor system of steam heating used on passenger equipment is applied to this car. With this system there is no steam pressure in the pipes inside of the car, the pressure being on the train line only. The controlling valves are located under the slatted floor at one side of the car, being accessible through a small door in the side of the car.

Connected with the pipes at each end of the car is a drain from the drip pan under the ice tank. This drain is arranged to receive the water from the melting ice, when the car is under refrigeration and conveys it to the same pipes used for heating. The cold water flows from each drip pan through the piping and is discharged at the center, and to one side of the car. The water is trapped at the center to keep the pipes full all the time the car is under ice.

At each end of the piping in front of the drip pan and under the slatted floor, are valves attached to the drain pipes from the drip pans. An extention handle is attached to each valve running through the side of the car, so they can be operated from the outside of the car.

At the side, accessible through the small door is a three-way valve to regulate the discharge of ice water, either through the trap under the car or through the goose-neck outlet. To keep the pipes filled with ice, water the handle of three-way valve should be turned crosswise with the car; the water will then discharge through the goose-neck. To drain the pipes of ice water, turn the three-way valve lengthwise with the car; the water will then discharge through the trap under the car.

In the wall of the car on one side, is placed a thermometer, the bulb being located in a pocket exposed to the inside of the car, while the registering plate is located flush with the outside of the car over which is a heavy glass and iron slide. The temperature inside the car may be read from the outside.

Car under refrigeration. — When the car is to move under refrigeration, the ventilators on the roof at the center should be closed and the air intakes at each end should also be closed, except as noted below. The drain valves at each end of the car in front of the drip pans should be opened, and while the car is under ice, the three-way valve should be turned crosswise with the car, so the pipes will remain full of ice water and discharge through the goose-neck outlet. When the car is unloaded or ceases to be kept under ice, the three-way valve should be turned lengthwise with the car, so the water in the pipes will drain off.

When the car leaves shipping point with a load of fruit, berries, etc., it is desirable to have a circulation of air through the car for the first one hundred miles or more, in order to carry off the heat and gases generated by the lading. It is therefore advisable to open the center ventilators and intakes at the end, until the load has become thoroughly cooled.

Car under ventilation. — When car is to run under ventilation without ice or heat, the exhaust ventilators on the roof at the center should be open and also the air intakes *at each end of the car*, care being

taken to see that *the hoods at each end face the direction the car is to move.* Air will then be taken in at each end of the car, passed down through the ducts, under and through the lading and out through the ventilators at the center. As each ventilator and air intake has a separate controlling handle or lever, the amount of ventilation required may be obtained by opening one or two ventilators in the center and one or two of the air intakes.

Car under heat. — When the car is to be heated, the valves at each end of the car connected with the drains from the drip pans should be closed. The three-way valve should be set lengthwise with the car and the steam control valve at the side opened. Hose connection is made at either end of the car the same as with passenger equipment.

It is not necessary that the car should have a constant supply of steam by running it next to the engine, *i. e.*, by having connection with steam supply from engine. While the car is being loaded, or after loading, steam connection should be made with a yard steam plug or other steam supply, keeping steam on until the temperature inside of the car is raised to the proper degree according to the kind of freight loaded. The car can then be safely run for twenty-four or more hours without steam. The thermometer at the side of the car will indicate when the car requires more heat.

CHAPTER V.

Additional matter regarding car heaters: Milwaukee heater, Economy heater, Peerless heater and Baxter charcoal heater.

Since submitting the original report, we have had our attention drawn to the following named appliances for artificial heat in cars during cold weather:

The Milwaukee heater. — Constructed on the principle of the oil lamp, with oil reservoir, rectangular in shape, surmounted by a burner and solid metal chimney, with supports for suspending from a ceiling of the car, and with flat the bottom permitting placing on the floor; burns "Headlight" oil, and can be charged to last forty-eight to seventy-two hours, dependent upon supply of oxygen in the car to be heated; two dimensions of wick, namely, 3 inches and 4 inches in diameter. The distinguishing features: 1° metal hood projecting from the chimney near the top radiating and forcing downward the head; 2° rectangular construction of reservoir, permitting location immediately in the corner of the car when suspended, minimizing jars from oscillation; 3° cushion springs as a part of suspensory supports equalizing vertical jars which might extinguish the flame. See cuts below showing heater complete

(fig. 12); also showing the heater in position for lighting suspended in the corner of car (fig. 13).

This heater is made in two capacities, namely; 5 and 6 gallons, and is listed at $15.

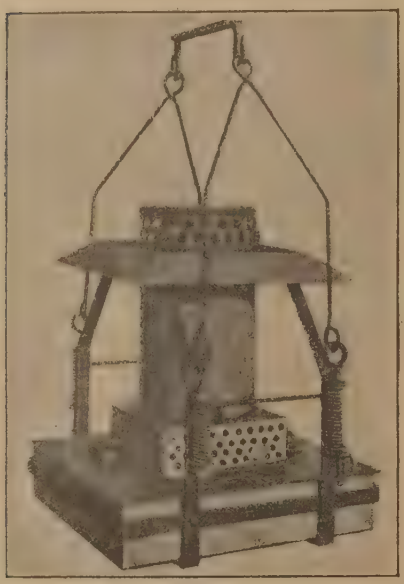

Fig. 12.

Fig. 13.

The Economy heater. — Constructed on the principle of the oil-burning lamp, with circular base and reservoir, surmounted by circular metal chimney; suitable for suspending from the ceiling of cars or placing on the floor; body of heater 17 1/2 inches in diameter, 9 1/2 inches high; metal stack or chimney 7 inches in diameter, 10 inches high; burner 5 inches in diameter, using cylindrical wick; burning head-light oil 150 proof; capacity of oil reservoir 2 gallons, lasting about twenty-four hours; capacity of water reservoir not shown. The distinguishing features : 1° location of reservoir containing water from which water is conducted to a tube 3 inches in diameter inside the burner, intended to cool metal parts and extinguish the flame in case of overturn; 2° construction of baffle plates inside of both water and oil reservoirs preventing the swashing and spilling of liquid. See cuts below showing heater open and closed (figs. 14 and 15).

The Van Evera Peerless heater. — We have not inspected one of these heaters and have only a description indicating that the heater is portable or stationary, and can be located in the car

or under the car; is built for a capacity of thirty-six hours, or more; burners and tanks supported by springs to equalize jolt and jar; tank to be refilled en route, or exchanged for tank filled and ready for use kept at convenient stations en route; construction designed to distribute heat at even temperature to all portions of the car by means of piping securing a greater draft.

Fig. 14.

Fig. 15.

The Baxter charcoal heater. — Designed and patented by W. H. Baxter; circular in construction; 37 inches high by 28 inches diameter; to be located only on the floor of cars; appliance consists of two parts; a magazine or receptical for the fuel (charcoal) with funnel-shaped bottom causing gravity feed; this magazine surmounts a cylindrical fire-box with conical grates and ash pans and provision for passage of air through holes in the sides (fig. 16). A competent authority describes the heater as follows :

A heater designed to burn charcoal and continue operation without attention, for a pre-determined length of time. The degree of temperature is regulated by varying the thickness of fire and not by changing the draft passage areas. This tends to keep a constant temperature which a change in draft would not do so well because the thickness of fire is more constant. The grate and ash-pan are both conical in shape, which insures a proper distribution of the fire and sloping down of ashes clear of the draft passages. The ash-pan will hold ashes of two weeks operation and the magazine (charcoal feeder) has a capacity of fifty to fifty-five hours and possibly sixty hours if the

charcoal is crushed fine enough. This is accomplished by putting it through a common corn-sheller.

Distinguishing features : 1° adjustment to operate for pre-determined length of time by regulating thickness of fire; 2° simplicity of construction eliminating largely risk of injury to heater and contents of car from mal-adjustment; 3° char-

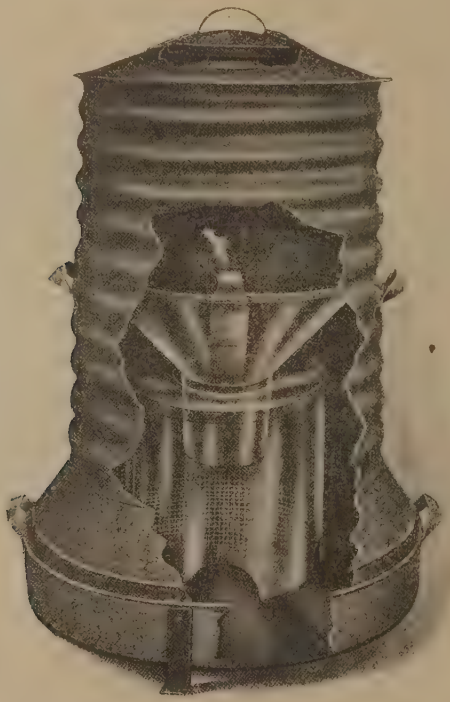

Fig. 16.

coal fuel, eliminating fumes of oil and danger of explosion; 4° automatic extinction of fire if overturned, through solid construction of fuel magazine and tendency of charcoal under ignition to be extinguished when draft is removed. This heater is listed to cost $15 to $20.

We observe that with respect to the oil burning heaters above described, the same have been utilized extensively in certain sections of the United States and have served a useful purpose. The two first described, adaptable either to hang from ceiling or placing on floor of car, the

details which we have explained above, show that in the main the attention needed en route is the same as would be given to an oil-burning illuminating device. On the other hand, actual experience has shown that less attention is required in the case of the Baxter Charcoal Heater, and there is smaller danger of explosion, deleterious odors and gases or damage by fire.

5TH SECTION — LIGHT RAILWAYS

OPENING MEETING

4 July 1910, at 5 p. m.

PROVISIONAL PRESIDENT MR. ERNEST GERARD,
MEMBER OF THE PERMANENT COMMISSION OF THE CONGRESS.

The President. (In French.) — Gentlemen, as I am the temporary president of this meeting, I have the honour to bring before you the proposals which the Permanent Commission has asked me to submit to you, relating to the appointment of the bureau of the 5th section. It is of course understood that you are at liberty to modify these proposals or to supplement them, if for instance you think that it is advisable to increase the number of vice-presidents or of secretaries.

I accordingly propose to you to appoint :

1° As president : Mr. G. BEHRENS, director of the Midland Railway (England), member of the Permanent Commission of the Congress, who is perfectly familiar with the three languages most used in our discussions. (*Applause.*)

2° As vice-presidents : Mr. C. DE BURLET, inspector-general of bridges and roads, general manager of the Belgian National Suburban Railway Company, member of the Permanent Commission of the Congress ; Mr. A. CAMPIGLIO, engineer, president of the Italian Union of railways of local interest and of tramways, director of the Milan Northern Railway, member of the Permanent Commission of the Congress ; and Mr. E. VON ZIFFER, engineer, president of the Lemberg-Czernowitz-Jassy Railway (Austria), who has done distinguished work about sundry questions. (*Applause.*)

If you wish to propose anybody else as vice-president, kindly let me know.

As nobody wishes to speak, I declare the proposals of the Permanent Commission adopted.

Provisionally, only one member has been proposed to act as principal secretary, namely Mr. JESSER, inspector, Austrian Southern Railway Company. Mr. Jesser, who is present, has kindly undertaken thesse duties. (*Applause.*)

Gentlemen, I declare the bureau formed and I vacate the chair which will now be taken by Mr. Behrens, who will

*

propose to you the appointment of the other officers of the bureau, namely the secretaries and secretary-reporters

Mr. Behrens. (In French.) — Gentlemen, in taking the chair and thanking you warmly for the honour you have bestowed on me in appointing me to preside over your labours, I wish to claim your kind indulgence if I do not always express myself correctly in French and in German, as English is my real mother-tongue. (*Applause.*)

— On the proposal of the president, the SECTION then appointed the other members of the bureau and drew up provisional agenda.

SECTION V : LIGHT RAILWAYS

[656 .27] QUESTION XVII

LINES BELONGING TO MAIN RAILWAYS BUT HAVING NOT MUCH TRAFFIC

(3rd and 5th SECTIONS MEETING JOINTLY)

Simplification in operating lines belonging to main railways but having not much traffic.

Reporter :

All countries. — Mr. Quarré, chief engineer, assistant traffic manager of the French Midi Railway.

[656 .27]

REPORT

By Mr. QUARRÉ,

CHIEF ENGINEER,

ASSISTANT TRAFFIC MANAGER OF THE FRENCH MIDI RAILWAY.

This question has already been discussed at three previous sessions of the Congress : at Milan in 1887, at St. Petersburg in 1892, and at Washington in 1905; but in neither case was it limited, as now, to lines not having much traffic, but belonging to main railways. On the one hand, it included the examination of the simplifications obtainable on lines of local interest; on the other hand, economic methods applicable even to main lines themselves were considered. Moreover other relative questions were also discussed at different sessions : Rolling stock for lines with little traffic (1892); Relaxation of normal requirements for light railways (1895); Automotor vehicles (1900 and 1905).

Thus all the economic methods of operation known, used or suggested, have already been considered in detail and repeatedly, and for all classes of lines.

When first discussed, this question was very much a question of the day. The development of the secondary or light lines of the trunk systems was already great, and the principles of their construction and operation, which were still the same as those laid down originally for the main lines, involved unnecessary limitations and expenditure all the more felt as the new lines yielded but low returns. It was therefore essential to compare the different investigations made by the administrations interested, with a view to placing the legislative provisions, the regulations and the methods of operation in harmony with the real requirements of the case; and to lay down the simplifications considered admissible by a body of undoubted authority, the decision of which could afterwards be invoked in favour of the modification of rules of excessive strictness.

*

This task, vigorously pushed forward, led on the whole to a satisfactory result. A number of countries today possess a light-railway legislation which is sufficiently liberal and which the railway administrations declare is satisfactory. It is true that there are still to be found legislations which do not draw all the distinctions desired between lines of the different classes; but it is easy to ascertain, by comparison with what has been done elsewhere, what improvements can be introduced. On the other hand, the known methods of simplified operation are sufficiently varied and numerous to make it possible to operate economically lower-class lines, in such a way as to satisfy both the requirements of safety and the convenience of the traffic. Thus it certainly seems that the study of the subject is nearly exhausted, as far as generalities are concerned; it can at present hardly consist in more than trying to investigate improvements in points of detail and examining the conditions now existing in the different countries; unless indeed, be it of course understood, some new process or method were evolved in addition.

In 1905, at the Washington Session, Mr. J. Rocca, reporter for all countries except America, Austria-Hungary, Germany and Holland, after remarking that the examination of economic methods of operation for lines not having much traffic (the question then referred to all lines not having much traffic, whether belonging to main railways or not) had already given rise to two important discussions, nevertheless considered it advisable to take up the question anew. It is to be observed that the last time the Congress had considered it was in 1892. On the other hand, Mr. Cornel de Tolnay gave similar information about the other countries, America excepted.

In spite of the ample material provided for discussion, if we refer to the reports of the meetings of the 1905 Congress, we find that no remark, no proposition, was brought forward on the subject of the different simplified methods of operation, and that the discussion at once took the form of an exchange of views on the possibility of running automotor cars on such and such gradients.

There is no doubt that at that time general attention was above all drawn to this subject of automotor cars, which were looked upon as capable of transforming the whole system of operation of light railways (1). This was evidently the only side of the question which led to its retention in the agenda of the Congress.

Be this as it may, and given the state of the question, taking into consideration also the very complete reports presented in 1905, we thought that it would suffice if we noted the particular points or changes which have taken place in this short

(1) We do not forget that certain automotor cars, such as the Belpaire cars, had been in use or had been tried on some lines quite a long time ago; but their use had not become extended. There is no doubt that it was the development of automobilism on highroads and highways which again drew attention to such cars; and in fact the problem could almost be considered a new one, as conditions were very different from what they had been previously. On the one hand, great improvements had been made in certain motors, on the other, there was the possibility that light railways would have to fear the competition of motor-car transport on the public roads.

period of time, paying however particular attention to everything connected with the utilization of automotor cars. With this object in view, we prepared a list of questions (see appendix), which was sent to 152 railway administrations. We received a comparatively large number of answers (68 altogether), but most of them were either purely negative or were limited to the statement that no modification had taken place, since 1905, in the methods of operating lines not having much traffic (1). These answers bear out the statement made above, that there is but little interest in taking up the discussion again, except as regards automotor cars; and as regards these, a larger number of the administrations of main railways have as yet not used them (even experimentally) on their secondary lines.

The field of our investigations was moreover too vast, and the time at our disposal too limited, to enable us to undertake long supplementary enquiries. Where we thought we could find data of some value, we nevertheless tried to obtain them, but such information has remained very incomplete. Thus our report practically only includes the information obtained in direct answer to our list of questions.

On the other hand, we have left out of consideration everything referring to narrow-gauge or electrified lines. The former, although administratively connected, in cases, with main railways, are necessarily operated separately, and enter rather into the class of lines belonging to a secondary system; as regards the latter, very few in number among these we are considering, they would not in any way contribute to a general and comparative examination of the subject, as exceptional causes have led to their electrification and to the peculiarities of their service. We should, moreover, have but few new or interesting particulars to present about these different lines. *A fortiori*, and for similar reasons, we have left out of consideration the particulars relating to railways belonging to any extraordinary class, such as the agricultural district railways known as *pioneer* railways in Australia.

Finally, we should have liked to collate statistical data on the results of operating some of the secondary lines of main railways, either operated according to a special system or by ordinary methods. We have received a certain number of figures, but the different railways have such different methods of accounting, and the information supplied is so incomplete, or in cases so involved, that we have been unable to draw up any instructive comparison. We will therefore limit ourselves, in this connection, to the statement which we shall now make at once, without returning to the subject later on, that there is nothing in any of the documents we have examined, enabling us to conclude anything as to the superiority of any one or other method of economic operation.

---

(1) We have received no answers from the administrations of the railways of the following countries : Brazil, Canada, Egypt, Spain, Greece, Mexico, Dutch Indies, Rumania and Servia. As regards the following countries : Argentine Republic, Belgium, Bulgaria, Algiers and Tunis, Norway, Portugal, Sweden and Turkey, the only answers which we received from some of the principal systems, were limited to the statement that there was nothing new or of interest to record.

As our report will form an extension of those presented at the last Session of the Congress, we are naturally led to adopt the classification of the Report presented in 1905 by Mr. Rocca, namely : 1° Legislation; 2° Lines economically operated; 3° Methods of economic operation.

We will consequently examine these different points in succession.

1° Legislation.

In the list which follows, we have only included these countries where legislation has been recently modified. In the case of the others, the state of affairs is the same as in 1905, with the possible exception of those about which we have received no information, their administrations not having answered our list of questions.

We would note that what we are considering here is not the legal phraseology of the concessions, or the administrative, financial or economic laws; what we wish to consider are the laws which distinguish between main lines and lines of a lower order, from the points of view of construction and of operation.

Finally, among such legal provisions we include all acts, decrees, etc., in fact all the orders issued by the superior authorities and which the operating administrations necessarily have to obey.

Germany.

A new *set of regulations on the construction and operation of railways* was issued 4 November 1904, and came into force 1 May 1905; this replaced the older regulations and more especially those concerning secondary railways, which had been in force since 5 July 1892. The principal alterations made in the older regulations are explained in the *explanatory remarks* annexed to the regulations.

Finally, on 1 August 1907, the following came into force : the *signalling regulations*, including the regulations proper, followed by the *executory prescriptions*, and the *prescriptions concerning the train service*. The principal modifications made in the older regulations are also explained in the *explanatory remarks*.

The new texts have been worked out principally from the prescriptions already in force, with some changes of wording to avoid ambiguity, and the matter treated is classified better. The actual innovations made on this occasion are but few in number, and are really only improvements in detail. The prescriptions concerning the train service, and the signalling regulations, do not include, as far as secondary lines are concerned, any alterations worth mentioning.

The regulations of 1 May 1905 authorize having the driver alone on the locomotive of a train; subject to the condition that a guard either comes on to the footplate while the locomotive is running, or that matters are so arranged that he can pass from his van to the cab of the locomotive, while this is running. This is a condition which is met with very frequently, when such an authorization exists.

This arrangement had been recommended, from 1886 onwards, by the technical commission of the German *Verein*, and it had been specified in the *fundamental principles* laid down by the general meeting of the *Verein*; but these *fundamental principles* only formed a common programme, and had no obligatory character.

Under the old secondary-railway regulations, the maximum train-speed authorized was 40 kilometres (24·8 miles) per hour, and this was only allowed in the case of passenger trains equipped with the continuous brake and having not more than 26 axles. It was permissible to add, at the tail of the train, cars not equipped with the continuous brake, but not more than 12 axles. Today, the speed may attain 50 kilometres (31 miles) per hour [1]. As for the maximum number of axles, it is fixed as follows :

80 axles, for speeds not exceeding 30 kilometres (18·6 miles) per hour ;
40 — — between 31 and 40 kilometres (between 19·3 and 24·8 miles) per hour ;
20 — — exceeding 40 kilometres (24·8 miles) per hour.

The two latter limits can even in certain cases be extended to 48 and 30 axles. Moreover, the regulation limits can be exceeded by 2 axles, for every 6-axle car contained in the train ; this provision is intended to promote the adoption of such cars, as their use is considered desirable and as contributing to increased safety.

It is permitted to hang on, at the tail of a train equipped with continuous brake, a greater number of cars not so equipped, than formerly. The maximum fixed for such extra cars is at present as follows :

30 axles, for speeds not exceeding 30 kilometres (18·6 miles) per hour ;
20 — — between 31 and 40 kilometres (between 19·3 and 24·8 miles) per hour.

No car not equipped with the continuous brake may be added to trains having a speed exceeding 40 kilometres (24·8 miles) per hour.

Finally, the brake tables have been revised, as regards the number of brakes the train must have; but the brake principles remain unaltered.

Austria.

The act of 24 December 1905, and that of 29 December 1908, extended the validity of the railway act of 31 December 1894 pending the promulgation of a new act concerning secondary railways.

---

(1) But only with the consent of the superior authorities of the country, and with the following restrictions : the cabins at the ends of the sections must be interconnected by telegraph ; the lines must be equipped with alarms or appliances for informing the gatekeepers when trains start ; junction stations must have entrance signals ; the level crossings without gates and not visible from afar, must be guarded when the trains pass ; finally information as to the starting of trains must be given by telegraph, in cases where no block system exists.

New regulations for operating railways of local interest were published, on 11 December 1905, in the form of an order issued by the Ministry of railways, and came into force 1 October 1906. The majority of the fundamental provisions is not affected, but the executory provisions are materially altered.

Signals ordering the drivers to sound their locomotive whistles must be placed near level crossings not provided with gates and placed in unfavourable or frequented portions.

The rules in connection with the coupling and uncoupling of cars have been made less strict. The employees are allowed to go between two cars, if these are moving slowly.

It is not necessary to intercalate a buffer car in the case of trains with speeds not exceeding 45 kilometres (28 miles) per hour (this limit was formerly 25 kilometres [15·5 miles] per hour).

The telephone may be used for transmitting orders and information concerning the train service.

The limits of the speeds of trains at switches, both at stations and on the line in the open, have been modified.

A locomotive may be used to push trains on certain sections, after authorization given by the Ministry of railways. Trains pushed by an extra locomotive (having one locomotive at the head and one at the tail), must not exceed a speed of 30 kilometres (18·6 miles) per hour.

The drivers of all the road locomotives may also act as chief conductors.

One important change in the train service consists in replacing the interval of time, between two successive trains running in the same direction, by an interval of distance (from station to station). No train is allowed to start from any station before information is received from the next station that the preceding train running in the same direction has arrived. This need not be done in the case of lines operated with one locomotive only. When no such information as to arrival can be obtained, a train may not be despatched till after the time normally required by the preceding train for the journey has elapsed, with a minimum of ten minutes. Moreover, in such a case, the driver must receive an order to proceed carefully, going at a sufficiently-low speed to enable him to stop in time in case of any obstruction of the track. Such an order of careful running is however not necessary if it is certain that the track is clear to the next station (for instance, when a train going in the opposite direction has just arrived).

The regular passing-places of trains cannot be altered unless a complete understanding has been arrived at by the stations concerned. The use of bell signals is not sufficient warning.

The cars can be left standing on the open track, for loading or unloading operations, provided the necessary safety measures have been taken. The first train which passes them takes these cars to the sidings of the nearest station.

New bases have been adopted for the braking, specifying the weight to be braked, according to the total weight of the train, the speed and the gradient.

Connecting the wagons by two side chains is no longer necessary. It is permissible to place two wagons without brakes behind the brake van carrying the signals, if the last of these two wagons is equipped with the signals necessary.

Where conditions are favourable, trains can run on lines of local interest not equipped with gates, at a speed of 40 kilometres (24·8 miles) per hour and in certain cases at even greater speed.

In the case of passenger or mixed trains running at speeds exceeding 30 kilometres (18·6 miles) per hour, the locomotive, the luggage vans and the passenger carriages must all be equipped with the continuous brake. When the speed does not exceed 30 kilometres (18·6 miles) per hour, a number of unbraked wagons may be added to such a continuous-brake train. The regulation proportion, of weight braked to total weight, is the same whether the vacuum brake or the hand brake is used. In the case of speeds exceeding 30 kilometres (18·6 miles) per hour, the addition of wagons not equipped with brakes is only authorized if the weight of the vehicles equipped with the air brake is sufficiently great to obtain, for the whole train, the proportion desired. The number of brakesmen is fixed, in accordance with the speed, as shown in the brake tables. When the weight of the wagons equipped with the hand brake only is greater than one fourth of the total weight of the train, the brakesmen are distributed, preferentially, over those parts of the train which are not acted on by the continuous brake.

Hungary.

New regulations on the operation of railways of local interest were issued in 1904, but the alterations are unimportant. An act concerning railways of local interest is in course of preparation, but its chief object is to revise the system under which concessions are granted and the conditions under which they are operated by the State; the principles of operation are to remain the same.

Great Britain.

The only thing we have to record is the answer sent by the management of the Lancashire & Yorkshire Railway, to the effect that fas ar as automotor services are concerned, the Board of Trade has made the provisions referring to the construction of the track and of the buildings, at stopping places between two stations, less strict.

India.

In 1907, the Government of India issued regulations concerning the train services on all the railways. These regulations include no particular provisions tending to simplify the operation of lines having but little traffic.

Australia.

An act modifying the government railways legislation was issued in 1907. The only detail to note is that locomotives are authorized to run tender forwards, whether running light or hauling a train, on district lines.

Italy.

Mr. J. Rocca in 1905 announced that the fundamental act of 20 March 1865, concerning railways, was to undergo a total reform, which would result, in the case of lines with but little traffic, in a profound modification of the act of 9 June 1901. While the latter only conceded certain facilities of operation in exchange for an increase in the number of trains per day and a decrease in the rates, the project which was being prepared included a number of liberal measures (1), applicable as a matter of right to all secondary lines, and even exceptionally to main lines. Mr. Rocca observed, with reason, that the facilities granted, being based on sound technical sense and on the progress made in the science and industry of railways, should not be made a matter of haggling, and sold to the companies at a correspondingly high price.

This reform, which certainly appears justifiable, has not yet been carried out. An act of 30 June 1906 was passed, but this upholds the principles of the act of 9 June 1901. According to the latter, trials of an economic service were authorized on lines or sections of lines of local interest having mean gross receipts not exceeding 10,000 lire per kilometre (£643 per mile) per year; and the corresponding reductions in the rates were to be 30, 35 or 40 per cent respectively, according as these lines yielded per year and per kilometre (per year and per mile), either more than 7,500 lire (£483), or from 5,001 to 7,500 lire (£322 to £483), or less than 5,000 lire (£321).

In the 1906 act, the above limit of 10,000 lire (£643 per mile) was replaced by one of 7,000 lire (£450 per mile) of receipts from passengers, luggage, dogs and bicycles, and the reductions in the rates only apply to these classes of traffic. These reductions are 30, 35 or 40 per cent respectively, according as the receipts in question, per year and per kilometre (per year and per mile), are either greater then 5,000 lire (£321), or between 4,000 and 5,000 lire (between £257 and £321), or less than 4,000 lire (£257).

This latter act is no doubt a slight improvement on that of 1901. It was logical to limit oneself to reductions in the tariffs in the case of the only classes of traffic

(1) Such as : doing away with fencing and with gates at level crossings, except in certain special cases, subject to the condition that the speed of the trains does not exceed 60 kilometres (37·3 miles) per hour, if they are equipped with the continuous brake, and 45 kilometres (28 miles) per hour, if not so equipped; the use of the telephone instead of the telegraph; the inspection of the track once per day.

which could grow in consequence of the conditions imposed, namely an increase in the number of trains. Moreover, this measure eliminated the complications which arose in connection with the goods-traffic accounts.

But the reform expected in 1905 is still far off, and so the anomaly continues to exist, that economic methods, having as their motive the smallness of the traffic, are only admitted subject to conditions tending to develop that traffic, and consequently to make those methods less justifiable.

United States of America.

The only point we have to record is the information supplied by the Central Office of the *Pennsylvania Lines West of Pittsburg*, that the provisions of the laws recently promulgated on the subject of the block system, do not apply to secondary lines on which the passenger receipts are less than a fixed minimum amount.

Switzerland.

An order concerntng the construction and operation of secondary railways was issued 10 March 1906, but it does not contain any simplification of the prescriptions which were then in force.

We had asked whether other laws or regulations, more especially those fixing the conditions and the hours of labour of the employees, and several of which have been issued lately, had any effect on the methods of operation previously adopted. As a general rule, such laws, while materially increasing the expenses of the railways, do not appear to have made it necessary to reorganize the existing services. In the third part of our report, we will however mention one particular measure (closing small stations at certain hours) taken in consequence of such legislation by the French Western Railway (now incorporated in the State system).

The railways of the United States of America complain very generally of the difficulties which arise from the application of the federal law issued 4 March 1908, which limits the hours and fixes the conditions of service of telegraphists, locomotive men and other employees. This law requires, for instance, that there should be a fixed interval between two consecutive runs, so that if a train arrives late at a terminus station, it must in cases start correspondingly late on the return journey, in order to enable its staff to have its legal period of rest (1).

This summary of the recent modifications made in legislation, in the different

---

(1) The Union Pacific informs us that this law has increased the expenses on secondary lines by about 10 per cent.

countries, appears to show clearly that a certain settlement in this fundamental part of the question has been arrived at. For very few laws or regulations have appeared during the last five years, and these are mostly coordinations, with variations in the details only, of existing prescriptions. However, most of the administrations in question, who have expressed their opinion on the subject, declare themselves satisfied with the existing state of affairs, which seems to them to be in harmony with a rational operation of the secondary lines of their systems.

We must, however, except the managements of the railways of the United States of America, which differ from what is the more general opinion, and think that the laws and regulations controlling them are much too stringent in the case of minor lines, and quite uselessly increase the cost of working. We think it of interest to quote some of the most striking answers on this point :

Boston & Maine Railroad. — American railroads are at present suffering from too much legislative provision which, while undoubtedly in many cases originating in a desire to rectify obvious faults, owing to lack of proper understanding of railroad conditions, is so framed as to but imperfectly accomplish the end desired while it entails large expense on railroads in complying.

Toledo, St. Louis & Western Railroad and *Chicago & Alton Railroad.* — Drastic legislation has made it impossible to effect any economy in operation of branch lines.

Delaware & Hudson Railway. — The present legislative provisions are obnoxious; less interference by the government in the handling of railroad facilities would save expense and facilitate the operation. The cost of making the reports demanded by national and state laws has alone enormously increased our operating expenses.

We may add that the legislation of the United States does not draw any distinction between main lines and secondary lines, but the railway administrations, taking into consideration the tendencies of the moment, do not show any desire for an alteration in the regulations in force, as they fear that instead of any alleviation there may be an aggravation in the burdens placed on them.

2° Lines economically operated.

In accordance with the preceding reports to which we refer, and although there is no accurate definition of lines economically operated, it is advisable to include, under this head, two kinds of lines :

1° In Italy, those with an *economic service*, specified by the legislation which treats them separately, only authorizing the facilities of operation granted under certain conditions (reduction of rates and increase in the number of trains); this prevents these facilities from being used on other similar lines, reasons of a technical character not entering into consideration;

2° In other countries, those which are classified separately from the neighbouring

lines, and which have a special administrative organization. This usually consists in entrusting their management to one sole manager who looks after all the service, and is only under the control of the central administration of the system. They remain subject to the general rules of technical operation of that system, and there are applied, there as well as elsewhere, different methods of simplified operation which are authorized and made possible by the existing special conditions.

These two classes have not actually, as between themselves, any close relation. The exceptional system of lines with *economic services*, instituted in Italy by the legislation, no doubt makes it evident that these are the object of special study, but in other cases, as regards lines *economically operated*, the real question is the method of simplified operation, the examination of which should, more logically, be dealt with in the subsequent part of our report. It would seem that it is only the similarity of the words which has led to this divison of *economic service* and *economic operation*. Moreover it is really of no importance, and having made this remark we will now continue.

As regards the former lines, the Italian State Railway has, since 1905, only established economic services on the Lecca-Francavilla-Fontana line, and on its Narda-Galatone branch; these were opened in May, 1907.

As regards the others, and excepting the Erie Railroad which has made trials of economic operation, but up till now without success, the railway administrations which already had such methods of economic operation, have simply continued them in those places where adopted, without further developing them; the reason being because they either have not come across new suitable adaptations of such methods, or perhaps because any very definite advantages had been realized in the trials already made. The Orleans Company (France), which had formerly declared that it would extend such methods, applied already to 237 kilometres (147 miles) of its lines, has done nothing in the matter. Similarly, the French Western (now part of the State System) which in 1905 had 1,242 kilometres (772 miles) of economically-operated lines, forming 23 sections, also remained unchanged. It must however be admitted, if we examine its railway system, that it appears to have adopted such methods, from the start, on nearly all the sections which were suitable for such special classification. This company estimated at about 15 per cent the saving in the cost of staff, which resulted from such an organization, but it is evident that this estimate refers to the whole of the measures taken, and not to those which, strictly speaking, constitute economic operation.

This measure is moreover of somewhat limited application, for it is necessary to find, in the first place, a group of minor lines, close together, sufficiently extensive to justify their management by an official of considerable capacity, such as is required for the purpose. Forming such a group also tends to the specialization of the employees, of the rolling stock, etc., and this may occasion difficulties. It

may even be asked if certain economies, either actually realized on those lines, or which are shown by the methods of accounting adopted, are not counterbalanced by increases, less direct and evident, but existing nevertheless, in the general expenses of the railway system.

In any case it must be recognized from the answers which we have received, that the situation, as far as economic operation is concerned, has hardly varied since the last Session of the Congress; and that at present the administrations of the great railways are not actively engaged in this direction in trying to find out how to effect savings in the expenses of their minor lines.

3° Methods of economic operation.

As regards the majority of these methods, such as : doing away with fences and gates at level crossings; doing away with alarms and distant signals, giving stations a limited service only, running shuttle services, having a female staff, reducing the number of passenger classes, etc., the administrations questioned have mostly limited their answers to the statement that they had not recently introduced any material changes in their methods of operation.

The general tone of these answers may be gathered from the following reply given by the Orleans (France) Company :

" No material modification has been instituted, since 1904, in the operation of lines with " little traffic. The former methods : running light trains, shuttle services, giving stations " a limited service, etc , have simply been either extended, or reduced, in accordance with " the variations in the traffic on the lines in question. "

The only actual points, more or less definite, which are noted are the following; they call for no remark and we only quote them for the purpose of being recorded :

The *Austrian Southern Railway* have adopted the normal system of main-line operation on certain local lines connected with main-lines, on which the traffic had grown considerably.

On the line from Steinbruck to the Hungarian frontier, there has been inaugurated, as regards the permanent-way service, a new system consisting in a complete separation of the level-crossing gate-keeper service and the line service. It is proposed to extend this system generally; it is expected that it will cost less and that the track will be looked after better.

The *company operating the Dutch State Railway* has extended its system of economic operation to the following lines : Coevorden to Gasselter-Nyeveen (55 kilometres [34 miles]), Assen to Bladskanaal (27 kilometres [17 miles]), and Marienberg to Almelo (19 kilometres [12 miles]).

The *Danish State Railway* has on one line only, that from Viborg to Herning (opened in 1906), entrusted the service at several stations to a female staff. Shunting operations at these stations are controlled by the train staff.

Finally the *Union Pacific*, in consequence of a great reduction in the traffic, has had to reduce the service on little-frequented lines, to the extent dictated by the circumstances. Trains have, for some time, only been run three times per week. Moreover, on the sections where the passenger traffic has shrunk, the trains have consisted of automotor cars.

This company remarks incidentally that in the United States of America, it is above all the main lines which have had their system of operation improved, by installing the block-system, strengthening the tracks, etc.

The same has also been the case in other countries, owing to the continual growth of the long-distance traffic; and this has no doubt contributed to the lesser attention paid to the service on lines with little traffic. More especially as regards the organization of local trains, with special stock, such as light locomotives and cars or automotors, it is evident that such an organization is rendered much less opportune by the fact that new locomotives and cars are obtained for the important trains, and consequently a number of the older locomotives and cars become available for use on such local lines.

Moreover, as we have already seen, the legislation having changed but very little and the methods of operation being already established, in many cases, in accordance with the facilities granted by such legislation, it is evident that for that reason also these methods were only liable to very limited modification. If in the United States of America, more especially, the stringency of the legislative provisions makes it useless, a priori, to try to find out how to effect savings by means of simplified methods of operation, it may be considered that in other countries the inverse is the case, that is to say there is already a satisfactory operation of lines of this kind.

However that may be, it is certain that if we pass today in detailed review all the methods of economic operation adopted, there would be much repetition. We will therefore only mention the following points, which in the present state of the question have appeared the only ones sufficiently interesting to place on record :

1° Use of the telephone.

The substitution of the telephone for the telegraph is becoming more and more general on the secondary lines. None of the administrations who have allowed this substitution mention that any inconvenience has resulted. This use of the telephone appears really advantageous, whether used by itself or together with the telegraph, according to circumstances.

2° Separation of the passenger and goods services.

The railway administrations have investigated the methods for realizing this separation, in order to make it possible, without excessive expense, to run quicker passenger trains more frequently.

These administrations however recognize that in spite of the new devices for reducing the cost per train-unit : reduction in the train staff, use of light rolling stock, automotor cars, etc., the system of mixed trains still remains in principle the most economic. They moreover consider that this system results in the best utilization of the goods wagons, thus resulting in very definite indirect advantages, which it is however impossible to calculate exactly.

The division of the quick-freight and slow-freight services no doubt tends to increase receipts from passengers, luggage and other accessory items, and consequently to counterbalance the increased expenditure which results, but we have not been informed of any conclusive examples in which this result, economic in the strictest sense of the word, has been attained; and finally it would seem that the considerations which have led to this separation are not the seeking for reduced expenses or increased receipts; it is rather the desire to satisfy the demands of the public, without any corresponding direct gain, to adhere to existing time-tables, to ensure connections with the main-line service, etc.

We will quote some of the answers on this points :

Bavarian State Railway. — The division has been carried out, so as to enable the goods services at smaller road-side stations to be attended to by the train staff, while the train stops at those stations. This system makes it unnecessary to keep a special staff at those stations; moreover, it makes it possible, under suitable conditions, to reduce to a minimum constructive works at the road-side stations of the local railways of recent construction.

This answer does not make it clear whether the solution adopted is economic or not. Moreover, it is to be noted that the results mentioned are obtained even with a service of mixed trains.

Wurtemberg State Railway. — Up to the present, we have not recorded any reduction in working expenses, resulting from the separation of the services. This organization, adopted on some secondary lines, has the object, principally, of enabling the passenger trains to keep to time. This separation has been carried out on some rather long lines with a considerable amount of passenger traffic, principally with a view to the acceleration of the faster trains, and in order at the same time to stimulate the passenger traffic. The working expenses have not been found to be reduced. Operation by mixed trains results in lowering the cost of traction; moreover, it makes it possible to move the wagons more quickly and more frequently, thus increasing the utilization of the rolling stock.

Austrian State Railway. — The separation of the services generally leads to increased expenses, for as there are but few passenger trains, it is impossible to reduce them still further. Under these conditions, every goods train run increases the number of trains by one. Running the latter makes it possible, under certain conditions, to develop the passenger traffic, but no particular economic advantage results. As a rule, separation is only effected if the mixed trains can no longer cope with the goods traffic. This system is also adopted when a line is connected with several foreign lines; this is the case with the local line Rakonitz-Pladen-Petschau, where the stops necessary at the stations resulted in lateness and in the missing of connections.

French State Railway. — The circulation of goods trains, instead of mixed trains, is dictated by considerations of convenience of service, and is generally not connected with the question of the receipts per kilometre.

Orleans Company (France). — We have tried to reduce, on some secondary lines, the number of mixed trains. The separation of the services on those lines appears to us to involve a greater cost of staff and greater general expenses, without appreciable financial gain to counterbalance this.

Paris-Lyons-Mediterranean Railway. — As a rule, the division of these services has not resulted in reduced working expenses. When we adopted this system, it was to improve the passenger service, by accelerating the trains, but such an organization is more rather than less costly.

Midi Railway (France). — Trials of separate services were made formerly, but are now abandoned as being too expensive, and not exercising an appreciable influence on the receipts.

3° The closing of stations or stopping-places at certain hours.

This measure has been adopted, more especially on the French Western Railway (now forming part of the State system), in consequence of the legislation on the conditions and hours of labour of the employees. It is worth mentioning, for when as a matter of fact excessive hours of labour do not result, it makes it possible to manage a station without extra staff, in the morning and in the evening; and at small stations, in between the times at which trains pass, there is no practical inconvenience in closing the stations during given hours, of which the public is duly informed.

4° Reduction in the train staff.

We will limit our examination to the case of a reduction of the number of employees on minor trains (called in the different countries : light trains, tramway trains, stopping trains, secondary trains) to two, only one being on the locomotive. This latter system, although it has now been authorized by a certain number of regulations for some time, is as yet very little applied and many administrations hesitate to adopt it in practice.

The principal reason for this hesitation is no doubt the obligation imposed on the driver to observe the track and the signals continually, but another reason is no doubt to be found in the rules for protecting a train which has stopped on the open track, accidentally. According to certain regulations, such a train must at once be protected at the tail by a train employee, whether the stop is short or long, and in many cases, that employee is not allowed to return to his place in the train, however long the stop may be. It follows from this that a light train, with a staff reduced to two men, is often, from this very fact, made incapable of resuming its journey.

Attempts have been made, in various ways, to overcome this difficulty. Thus, with the system adopted in Germany, and more recently in Austria, that is to say, with a service of trains going in the same direction separated by station-to-station intervals, which really forms a sort of telegraphic or telephonic block-system, it is evidently possible to simplify extensively the rules for protecting the rear of a train. Another system has been selected by the Orleans Company (France). It consists in increasing by fifteen minutes the regulation interval of time between a light train and whatever is the next train; this makes it possible to leave the former unprotected, in the case of any unexpected stop between two stations, during any stop shorter than that increase (1).

Without examining this detail more closely, we will now mention the applications already made by sundry administrations, either in current practice or as an experiment, of the system which consists of having one man on the locomotive only and thus makes it possible to reduce the whole train staff to two men.

Germany.

Alsace-Lorraine Railway. — In certain isolated cases, locomotives are used on which the whole staff consists of one driver only. These locomotives are designed so as to give access to the first car of the train, and arrangements are made so that the train is accompanied by a second employee, capable of driving the locomotive in case of necessity.

On the Bischweiler-Oberhofen line (passenger service only), the driver and fireman also act as conductor and guard, and there is no other employee on the train.

Baden State Railway. — Formerly the tank-locomotives of a local train service running between Carlsruhe and Ettlingen (main line) were managed by a driver alone. The chief conductor had access to the driver's cab, through a door in the back of the tank-locomotive. This system has been given up and there are now two men on each locomotive.

Bavarian State Railway. — By the application of the new regulations of 1 May 1905, there have been instituted, in 1905, on the main lines and in 1906 on the secondary lines,

---

(1) Another system which makes it possible to simplify these protective regulations materially, not only as regards a train, but as regards any other obstacle on the line, results from the acceptation of this essential principle, that the line is normally clear after a train has really passed, and up till the time the next train is actually due. This principle can of course only be accepted subject to the condition that no other extra train is despatched on the line, without having notified its times of running to all the employees concerned.

When this rule is accepted, it is not only possible to leave unprotected a train which has stopped on the track, until the moment of arrival on the next train, but also, to create some obstacle (replacing a rail, sundry repairs, etc.) without continually protecting it from a distance; and this results in a material saving in working expenses. It is even possible, under certain conditions, to run over the track, for instance on a tricycle trolley, which facilitates the inspection of the line. This system is in force on the standard-gauge system of the Landes Railway, a system which is of local interest, and as such outside the scope of our report, but which is closely allied with the French Midi Railway. Moreover nothing would prevent the adoption of this system on the secondary lines of main railways.

light trains for local traffic. On the main lines, these trains can only take 60 per cent of the load authorized for the locomotives hauling them; on the secondary lines, the maximum load authorized is 65 tons.

The light trains run at an average speed of 60 kilometres 37·5 miles per hour on the main lines and at one of 40 kilometres (24·8 miles) per hour on the secondary lines.

On the former, they are accompanied by either a driver and a fireman, or by a driver and a chief conductor. In the former case, the fireman carries out the duties of the conductor. This system is still in the experimental stage.

On the secondary lines, the train staff consists of a driver and a chief conductor. Tank-locomotives of recent construction are used, designed for automatic stoking. The chief conductor can, while the train is running, pass from the cars to the locomotive so as to stop it, should the driver become incapable of carrying out his duties (1).

It has also been recognized possible to have only one man on a locomotive, without any special arrangements, if the train load is such a reduced one that it is unnecessary to renew the fuel on the grate too frequently. It is moreover indispensable that the chief conductor should be on the locomotive while it is running, so as to assist the driver by keeping the track under observation, while the driver is engaged in the firing operations. In such a case, neither the locomotive nor the cars require any modification.

Saxon State Railway. – On the secondary standard-gauge line between Frohburg and Kohren (7·8 kilometres [4·8 miles]), which was opened 1 May 1906, the trains are hauled, as an experiment, by locomotives having a driver only, who is assisted, as far as possible, by a train-hand who understands the working of the locomotive sufficiently to be able to stop it. In order to give access from the cars to the locomotive, a passage-way consisting of a movable platform has been established.

Wurtemberg State Railway. — The system has not yet been tried, but experiments are going to be made shortly.

Austria.

Austrian State Railway. — The light locomotives, which are as yet used only to a very limited extent, are managed by a single man, if the following conditions applying also to steam motor cars) are satisfied (2) :

It is a general rule that the management of the boiler or of the engine must not prevent that employee from bringing to bear, on the observation of the track and of the signals, that attention which is required from the driver of a locomotive on which there are two men.

As regards steam engines, the fuel must be supplied automatically, or else matters must be arranged so that the whole of the stoking can be carried out during the stops. Devices which make it necessary to open the fire-door while running may not be used.

---

(1) It is to be noted that the Bavarian State Railway is carrying out these experiments on the reduction of the train staff, both as regards automotor cars on their main lines, and as regards light trains, composed of rolling stock of ordinary type, on those lines which have but little traffic.

(2) There are only three locomotives and one steam motor car equipped with a view to being driven by one man only. One of these locomotives is of ancient pattern and is equipped with a simple device for feeding the fire. The other two and the steam motor car are of recent construction and burn oil.

Moreover, on secondary lines, the engine must be so designed that while running it never requires more than momentary attention. All the appliances which the driver has to watch, must be visible to him when he is in the position he occupies when observing the track.

It is indispensable that there should be a means of communication between the locomotive and the cars of a train; or in case of an automotor car, between the driver's compartment, the other compartments and the trailers, if any.

When an automotor car, driven by one single man, is constructed in such a way that the driver cannot observe the track properly when he is in the compartment containing the motor, then the chief conductor, who then has to undertake this observation, must be able to operate the whistle (or the bell), the gear for stopping the motor and the brakes.

As a general rule, in the case of every train hauled by a locomotive driven by one man only, one of the other employees on the train must be acquainted with the duties of a driver.

Austrian Southern Railway. — On the Laibach-Oberlaibach line (11·5 kilometres [7·15 miles]) the locomotive is driven by a single man.

Hungary.

Hungarian State Railway. — Recently trials have even been made with small locomotives equipped with special stoking gear. On the automotor cars, on the other hand, in addition to the driver there is also a fireman or other assistant.

France.

Orleans Railway. — The system is not yet used, but the methods of applying it are being investigated.

State Railway. — In some cases there is one employee only on the locomotive. The design of the rolling stock has been modified so as to enable the conductor, who is in the first car behind the locomotive, to have an easy access to the latter by means of the footboards.

Paris-Lyons-Mediterrancan Railway. — Trials were made, and then given up.

British Colonies.

Central South Africa Government Railways. — The question is being considered and when certain difficulties of minor importance have been overcome, the system will be applied.

5° Use of special stock.

Such stock, whether locomotive or rolling stock, may be merely of ordinary type, but light and specialized for use on a minor line. In other cases, though of current type, it may have some peculiarities : cars with intercommunication, tank-locomotives designed or not designed to be operated by a single man, etc. Finally, the

stock may consist of automotor cars, that is to say, of cars where each car contains both its own engine and all or part of the rolling stock forming a train; in this class we may include the motor luggage-vans.

We will not repeat the arguments, often advanced, as to the advantages or disadvantages of specializing the rolling stock and of utilizing given cars, designed especially for a given service, on a secondary line or group of secondary lines. A very complete summary of them is to be found in the report of Mr. Sigismond Adeles on the rolling stock of lines with little traffic (1892 session).

In accordance with the plan we have set ourselves, we will only note the alterations since the last session of the Congress. With this object in view, and referring to the information given above as to the scheme of reducing the total number of train men to a minimum of two, we have nothing new of any importance to record, except as far as automotor cars are concerned. This could hardly be otherwise, as it is just with such cars that attempts have been made to improve local services.

That is therefore the only point to which we can attach importance, and we will only refer incidentally, or by way of comparison with the automotor cars, to the matters concerning light locomotives and carriages.

In the summary which follows, we only include those administrations who informed us that their stock for lines with little traffic included automotor cars, and that they had since 1905 more or less modified their system of operation by the use of such cars.

Although we deal exclusively with such lines, we have also referred to the use of such cars on other sections, particularly when any interesting general information resulted from such cases, or when the services organized were operated both on main lines and on secondary sections. Moreover in the case of certain answers, it was difficult to avoid confusion and to disentangle what applied to local lines only.

Finally, it is evident that we have not tried to describe in detail the types adopted, as this would have trenched on question XII (IV of the 3rd section) of the 1910 Congress, which more especially deals with the subject of automotor cars.

Germany.

Bavarian State Railway. — Several automotor cars are running, *but chiefly on main lines :* several suburban trains, on lines running out of Munich, consist of automotor cars.

At first, rather a considerable number of such cars had been put in use, but it was necessary to give them up because it was too often necessary to substitute trains hauled by locomotives. It may be stated, generally, that the automotor cars are laid up for maintenance or repairs during a considerable number of days; they are more frequently laid up than other stock.

Wurtemberg State Railway. — Leaving out of consideration a small narrow-gauge line, on which all the trains are composed of a steam automotor car, with or without

trailers, the Wurtemberg State Railway owns, for use on nineteen of their standard-gauge lines or branches, thirteen steam automotor cars (eleven running and two as reserve), and four benzene automotor cars (three running and one as reserve); but *these run nearly only on main lines.* When an automotor train runs on such a line, it simply continues on a branch line, when this continuation can be conveniently included in the run and no other rolling stock is required. There is only one daily run, in each direction, which is effected by one of the benzene automotor cars, and that is on a branch line, 16 kilometres (10 miles) long, starting from Lentkirch. In the case of steam automotor cars, these are only to be found on one section, 6 kilometres (3·7 miles) long, of the line from Plochingen to Kirchheim (five trips daily in each direction), and on the line from Reutlingen to Pfullingen, 5 kilometres (3 miles) long (two trips daily in each direction).

The Wurtemberg State Railway possesses altogether eleven secondary standard-gauge lines and five narrow-gauge lines.

The benzene automotor cars run without trailers and are only used in cases where there is very little traffic. They provide sitting accommodation for forty four passengers and standing room for eight, and there is no luggage compartment. The steam automotor cars are of two different patterns : one provides sitting accommodation for forty passengers and standing room for eight, and there is no luggage compartment; the other provides sitting accommodation for thirty-two passengers and standing room for four, and also has a small luggage compartment which can be converted into a passenger compartment with eight seats. It is the latter which are to be found on secondary lines. The automotor cars can take three trailers as a maximum, on certain runs. With two trailers, each with forty-four seats, they attain a speed of 50 kilometres (31 miles) per hour on the flat and one of 25 kilometres (15·5 miles) per hour on a gradient of 10 per mil.

During the working year 1906-1907, the steam automotor cars, taking main and secondary lines together, had to do an average daily run of 156 kilometres (85 miles) (maximum, 200 kilometres [124 miles]; minimum, 100 kilometres [62 miles]); and the benzene motor cars, one of 170 kilometres (106 miles) (maximum, 282 kilometres [175 miles]; minimum, 128 kilometres [80 miles]).

The stop which is necessary between two consecutive journeys, can be very short. The benzene automotor cars are always ready to start. The grate of the steam automotor cars is, as a rule, only cleaned out once, before the start, and keeping the engine in working order only necessitates one stop per day, in order to take in water; a supply of water is only required twice a day.

The whole service is never operated by means of automotor cars only; these only run in between the other trains. As there are only three reserve automotor cars, at Saulgau, Friedrichshafen and Tübingen respectively, it is necessary to substitute, the case arising, trains with locomotives; but as it is generally known in advance on what days there will be much traffic, those days are utilized for washing out the boilers and doing any repairs.

During the year 1906-1907, each of the twelve steam automotor cars which were then owned (there was no reserve) ran, on the average, on 204 days (maximum, 306 days), and the benzene automotor cars each ran, on the average, 195 days. Although these figures would appear to show that the automotor stock was laid up rather frequently, the administration of the Wurtemberg State Railway does not think that automotor stock is laid up more frequently than ordinary stock.

Finally, the management declares itself satisfied with this organization and considers it economic.

Austria.

Austrian State Railway. — Actually only two steam automotor cars, on the Komarek system, are used on the local lines Laun-Libochowitz and Cercan-Modran. Up to 1907, another steam automotor car, on the Komarek system, was run on the Wels local line, but is no longer used now.

The automotor cars are only used conjointly with ordinary trains. There is no reserve, and whenever necessary, trains with locomotives are substituted for the automotor cars.

The two automotor cars in use each have accommodation for eight second-class passengers, and for twenty-four third-class passengers, and also a luggage compartment, which can accomodate five passengers. They are reserved exclusively for the carriage of passengers and luggage. A trailer may be added.

Their regulation daily run was, in 1906 and 1907, 112 kilometres (70 miles) in the one case and 107 and 152 kilometres (82 miles) respectively in the other. They actually ran, on the average per day : the first 84 kilometres (52 miles) in 1906 and 65 kilometres (40 miles) in 1907 : the second 77 kilometres (48 miles) in 1906 and 82 kilometres (51 miles) in 1907. This represents a coefficient of utilization varying between 62 and 75 per cent.

These cars, when running by themselves, can attain speeds of 50 kilometres (31 miles) per hour on gradients of 9 per mil, and about 27 kilometres (17 miles) per hour on gradients of 25 per mil ; and if hauling a trailer weighing 10 tons, speeds of 30 kilometres (31 miles) per hour on gradients of 6 per mil and 25 kilometres (15 5 miles) per hour on gradients of 20 per mil.

If we take all the steam automotor cars into consideration, both on local lines as well as on main lines, the stop necessary between two consecutive journeys differs considerably ; it varies between 5 and 30 minutes.

When the automotor cars were first run, it was frequently necessary to substitute ordinary trains. It is evident that this entailed extra expense, so that the automotor cars did not give very brilliant financial results. It is true that these disadvantages have gradually been reduced, as more and more improvements were introduced in the construction of the motors.

Austrian Southern Railway. — On the one line from Barcs to Slatina, a steam automotor car runs 90 kilometres (56 miles) per day. One car is running regularly and there is another as reserve.

Each contains nine second-class and twenty-five third-class seats, and standing room for six passengers. They run normally with a trailer ; the gross weight of the train is 30 to 35 tons and the maximum speed on the flat is 45 kilometres (28 miles) per hour. The steepest gradient on which the automotor car can run by itself is 30 per mil.

The stop between two successive journeys is at least 30 minutes long.

The automotor cars often have to be replaced. They were laid up for repairs 116 days per year on the average, or 31·7 per cent of the time. This ratio is 21·6 per cent in the case of locomotives.

Hungary.

Among the railways of local interest operated by the State, there are thirteen operated by steam automotor cars since the end of 1907. There are twenty-two such cars; they are equipped with de Dion-Bouton motors. Normally they haul one trailer, and exceptionally two. There is accommodation for from 100 to 120 passengers. The maximum weight of a train is 40 tons. Taking into consideration the number of cars usually running, there is a reserve of about 30 per cent.

The average distance run by each car is about 30,000 kilometres (18,600 miles) per year. The shortest stop between two consecutive journeys is thirty to forty minutes.

When there is a sudden rush of traffic, trains with locomotives are substituted for the automotor cars. It often happens that such substitution is necessary, and this exercises an unfavourable effect on the results of this system of working. On the average, each automotor cars runs on about 180 days of the year.

It is to be noted that these automotor cars are driven by two employees, a driver and a fireman or motorman; but on the small locomotives which have lately been introduced and which are equipped with stoking gear, there is only one employee.

The matter is still in the experimental stage (1).

United States of America.

Among all the administrations which have sent us answers, there is only one, the *Union Pacific*, which owns automotor cars; and it declares that it is very satisfied with their working.

The following is a summary of the information supplied by that administration :

Nine cars with gazoline motors are in use and thirty-two more are being built. The first was constructed as an experiment. It has two axles and its weight is about 20 tons. It began, in August 1905, a regular service between Kearney and Callaway (Nebraska) and makes each day a trip in each direction (distance, 65 miles).

The others are on bogies, and have 6-cylinder gazoline motors, the power varying between 100 and 250 horse-power; their total length is about 17 metres (56 feet). They can carry from 57 to 80 passengers. They are built entirely of steel; the front is tapered off to form a wind-cutter, the roof is arched and the end is rounded off.

They are designed for high speeds, and can run up to 104 kilometres (64·6 miles) per hour.

In a few cases they run by themselves, but as a rule they haul a trailer which is intended for luggage, mails and express packages.

Their average daily run is 99 miles. Of the nine cars, three act as reserve.

---

(1) According to the most recent information, the Hungarian State Railway is now utilizing automotor cars on fifteen lines (we were unable to ascertain on what class of lines). On thirteen of these lines there are steam automotor cars; the power of the motors varies between 35 and 80 horse-power. There are fifty-two automotor cars available; fourteen of them serve as reserve and five are used for extra or special trains. On the other two lines there are petrol-electric cars, on the de Dion-Bouton system; on the one there are three automotor cars running, with one as reserve (power of the motors, 70 horse-power), on the other, there are two automotor cars, of 25 horse-power each.

If there is a rush of traffic, other trailers are hung on and it very rarely becomes necessary to substitute for them trains with locomotives.

The mean number of days on which they run is 25 per month; they are not laid up more frequently than other vehicles.

No change has been introduced, in consequence, in the general working regulations. Two automotor trains are run each day in each direction. Slow-freight packages and part of the quick-freight packages are conveyed by trains hauled by locomotives.

The staff on these automotor trains has been reduced from four to two men. The four men were paid 365 dollars £73 per month, and the two men replacing them only receive 170 dollars (£34) per month.

Taking it altogether, this organization, which has been extended to 40 per cent of the secondary lines, is on the one hand very economical, and on the other is much appreciated by the passengers.

We should have liked to obtain particulars of the conditions and of the traffic of the different separate lines or groups of lines on which this system of operation is in use, but we have been unable to obtain useful details on these points.

It may be noted, it is true, that the cost of staff was high and the cost of materials, tools and fuel comparatively low, so that it was possible to adopt gazoline motors of high power; thus there were very favourable conditions, which might be lacking in other countries. But it may be asked why other railways in the United States of America have not tried similar methods.

France.

Orleans Railway. — The Orleans Company is running steam automotor cars, on the Purrey system, on several secondary lines; but here is not a case where they are used not for light traffic only but also on lines with an ordinary amount of traffic (Vierzon to Bourges).

These cars are used on isolated sections, but these are grouped around four centres: Tours, La Flèche, Bourges and Le Blanc. They provide accommodation for fifty-five passengers, twenty-five first-class and thirty third-class, have a luggage compartment (10 square metres [108 square feet]) and a half-compartment for mails.

They are used either by themselves, or with one or at most two trailers: passenger carriages or luggage vans or parcels vans.

The daily runs are: at Bourges, 101 kilometres (63 miles); at La Flèche, 104 kilometres (65 miles); at Le Blanc, 115 kilometres (71 miles); at Tours, 220 kilometres (137 miles) (with two shifts of men).

They must stop at least one hour and a half at the station, after running 80 kilometres (50 miles) as maximum, so as to enable the grates so be cleaned out and the fires to be started afresh. This time must be extended to two hours at the terminus stations where the driver alone has to attend to the different operations, such as turning round the car, attending to it and preparing it for the return journey.

After running 30 to 40 kilometres (18 to 25 miles) as a maximum, it is possible to run the same distance over again, without completely drawing the fires and lighting up again, subject to the condition that the stop does not exceed from twenty to twenty-five minutes.

If the stop is to be longer, it is better to start the fires afresh, and then we again have the former case of a stop of at least one hour and a half or two hours.

The Orleans Company has nine automotor cars running and four as reserve, two of which consist of a motor truck only.

The number of reserve cars can probably be reduced in the future, when it is more definitely ascertained how many cars are really required.

The automotor cars must occasionally, in cases of a sudden rush of traffic, be replaced by ordinary trains. The increased expenditure which then results reduces the advantages obtained by means of the automotor cars. Each car is on the average laid up 93 days per year, or 25 per cent of the time. The average time the ordinary passenger locomotives at the stations where the cars are placed) are laid up is about 60 days per year, or 16 per cent.

The use of these automotor cars on lines with little traffic is as yet too recent to make it possible to give a definite opinion as to their merits.

French Northern Railway. — The French Northern Railway has made several trials of automotor cars. In 1895, it tried an electric car, with accumulators, with sitting accommodation for twelve first-class and thirty third-class passengers, standing room for sixteen passengers and a luggage compartment. In 1896, it built another electric car intended chiefly for mails, but also having sitting accommodation for twelve second-class passengers, and capable of hauling one or two passenger carriages. This car was then altered and trials were made with it, in 1901 on the line between Creil and Beaumont.

A steam automotor car, on the Serpollet system, was set running in 1897 on the Creil-Beauvais line.

A second steam automotor car was built at the same period, for suburban service. This consisted of three parts : in the middle, the driver's compartment, the boiler, the engine, and a small luggage compartment which could if necessary be converted into a third-class compartment for six passengers ; at one end, a third-class section ; at the other end a composite first-second class section. Altogether there was room for 82 passengers.

At present, the company is starting, as and when they are delivered, a series of eight cars of this type. These are at present being tried, provisionally and until sufficient experience has been obtained to prove that they can be depended on for definite suburban trains, for services where there is but little traffic. But they are already not considered as special stock for lines with little traffic only.

State Railway. — The State Railway some years ago tried two automotor cars, on the Purrey system, for the Bordeaux suburban service, between Bordeaux and St. André de Cubzac. It was not possible to carry out a continuous and regular service with them ; and they have now been stopped in order to be reconstructed. The administration of the State Railway is not able to give any definite information as to what will be done with them in the future.

On the other hand, this administration has given up the use of the locomotive-luggage-vans which had been built a certain number of years ago. This type of car had seemed very satisfactory as regards the desideratum of having the chief conductor and the driver who alone attended to the motor, close together, but the luggage-van space available had been too limited. At present, if it is desirable to design special stock for lines with little

traffic, the State Railway would seem to prefer small locomotives, capable of being driven by one man only, and light carriages.

Midi Railway. — The Board of Public Works has strongly recommended the French railway companies to adopt automotor cars on the secondary lines. In answer to one of these recommendations, the Midi Railway submitted, in January 1907, the following remarks which we think it will be of interest to reproduce here :

" From the point of view of the organization itself of the service, it is evidently of little " importance whether a train consists of an automotor car with or without trailer, or of a " light locomotive only hauling one or two carriages of ordinary pattern.

" In the absence of automotor cars and as a first experiment, we tried to operate two " of our lines, Carmaux-Rodez and Quillan-Rivesaltes, which seemed to us suitable for " the purpose, by means of tramway trains, which could very simply have been replaced " later on by automotor trains.

" This system has now been working for more than two years on the Carmaux-Rodez " line and for more than one year on the Quillan-Rivesaltes line. On the former, where " two tramway trains and two ordinary trains ran each day in each direction, the two " former had almost at once to be replaced by ordinary trains on Saturdays and on the " Rodez market-days; and also, during summer, on all Sundays, owing to the large num- " ber of tourists visiting the Viaur viaduct.

" On the Quillan-Rivesaltes line, there were also two tramway trains and two ordinary " trains each day in each direction; here one of the tramway trains had to be replaced by " an ordinary train during the whole grape season, that is during more than one month. " The same measure had to be taken on the Perpignan feast and market days.

" In spite of this, we have received numerous complaints in connection with the restric- " tions, on these tramway trains, to the admission of passengers, luggage and parcels.

" The difficulties which resulted from having to substitute ordinary trains for the " tramway trains would have been still more serious if automotor cars had been used.

" These difficulties, which as a matter of fact we had foreseen when we proceeded to " this special organization adopted on the Carmaux-Rodez and Quillan-Rivesaltes lines, " would arise everywhere else, on all of our other lines on which services or automotor " trains could be organized; they would even no doubt be more marked, as we natu- " rally selected, in the first place, those lines which seemed to us most suitable for such " experiments.

" It cannot be denied that the use of automotor cars is no longer practical, if it postu- " lates the necessity of having specially, and always, an ordinary train in reserve to deal " with sudden rushes of traffic on certain days.

" We may add that as the automotor cars are liable to numerous break-downs, their use " cannot be advisable except on lines near depots and workshops and grouped around one " centre, so that there need not necessarily be two automotor cars for each car that is " running, the second acting as reserve to ensure the running of the train in question. " Now on our railway system we have no points where all these different conditions apply.

" Taking it altogether, the experiments which we tried and which, as far as carrying " the traffic was concerned, exactly correspond with what would have resulted if auto- " motor cars had been used, gave but very mediocre results, giving but little encourage- " ment to the undertaking of other experiments of a similar kind.

" We therefore think, that taking into consideration the position, the conditions and the " circumstances in connection with our secondary lines, any improvement in the service " on these lines is not likely to result, at all events at present, from the use of automotor " cars."

In addition, a Purrey automotor car was tried in 1908 on the Bordeaux-Arcachon line, for suburban traffic; thus it was not a question of a line with little traffic. The experiment was given up, as the traffic varied so much that it was too frequently necessary to substitute an ordinary train for the automotor-car.

Paris-Lyons-Mediterranean Railway. — This company owns several automotor cars for use on isolated sections with little traffic. It has tried to group the automotor cars at points sufficiently near each other, but has not quite succeeded in doing so, on account of the difficulty of finding, in one and the same district, lines suited to such a system of operation.

It actually owns automotor cars of two types, both with steam motors on the Purrey system. In the first type the boiler and engine are carried on the underframe of the car itself; in the second, the boiler and engine are on a truck separate from the body of the car. The company has six cars of the first type and twelve of the second.

The cars of the first type have no luggage compartment. The motors are of from 130 to 140 horse-power. There is room for from ten to twelve first-class and from thirty-six to forty-one third class passengers, standing room for twelve on a platform included. The tare is 19 or 20 tons, and the weight when fully loaded, about 24 to 26 tons.

In the second type, the motors are of 150 horse-power, the tare is 30 tons and the weight, when fully loaded about 36 tons. There is room for twelve first-class and forty-seven third-class passengers, a compartment for mails and a compartment for luggage.

The original plan was that these cars should normally run without trailers. However a trailer is now added and in some cases a luggage van or goods wagon.

These cars run as follows :

—	Daily run.	Number of automotor cars running.
Alais to Ardoise	116 kilometres (72 miles).	1
Lunel to Sommières	91·8 — (57 —).	1
Uzès to Nozières	75·6 — (47 —).	1
Arcy-la-Tour to Gilly	85 — (52·8 —).	1
Beaune to Allerey	106·2 — (66 —).	1
Dôle to Poligny	119·1 — (74 —).	2
Mouchard to Salins	148 — (92 —).	1
Montbéliard to St. Hyppolyte	127·2 — (79 —).	2

When it is necessary to have two automotor cars at one point, there is generally one in addition, as reserve.

The minimum length of stop is as a rule dependent on the station installations and limited to the operations of turning the cars, taking in fresh supplies and attending to the engine; it varies on the different lines and on the length of the journey made.

In certain cases, the use of automotor cars has made it necessary to incur expense in the installation of turntables.

As a rule, the cars and ordinary trains run concurrently.

The fact that on days when there is a rush of traffic, the seautomotor cars have to be replaced by ordinary trains, materially reduces the advantages of this stock.

The Company states in conclusion that this organization has now existedbut a short time, and that at present it is still in the experimental stage, The automotor cars have not run sufficiently regularly to make it possible to give any reliable information as to the economic results given by this system.

Great Britain and Ireland.

Great Central Railway. — This company, for the service on some lines with little traffic, has three automotor cars proper, that is to say, cars containing their machinery. They are steam cars, with vertical-tube boilers carried on one of the bogies of the car.

A fourth automotor car owned by this company is really a bogie carriage coupled up with a small tank-locomotive, so arranged that the engine is always at the same end of the carriage, no matter which direction it is running in. The regulator, the reversing gear, the vacuum brake and the steam whistle, can be operated from a driver's compartment located at the other end of the car, whenever this is pushed by the locomotive.

These automotor cars are used with one or two trailers. They accommodate, according to type, from twelve to sixteen first-class and thirty-six to forty-eight third-class passengers, and have a luggage compartment.

Each of these cars is ordinarily running on the lines Barton to New Holland, Wrexham to Brymbo, Woodford to Banbury, Aylesbury to Verney, and there is no reserve. The service is operated on all these lines conjointly with trains hauled by steam-locomotives and when it is necessary, the automotor cars are replaced by ordinary trains.

As an example, we will take the car running on the Aylesbury-Verney line, which is satisfactory from the point of working; but allowing for the days on which it was not wanted, it was laid up 43 times to 270 days of work. It is thus evident that these automotor cars have to be laid up, for maintenance and repairs, more frequently than locomotives of the current types.

The use of these automotor cars does not seem to be very economical.

Lancashire & Yorkshire Railway. — On some of the branch lines, automotor cars are used consisting of a steam-locomotive joined to the carriage body and forming one combined vehicle. The weight of the motor, carried on bogies, is 14·5 tons empty and 16·5 tons in working order; the total weight of the car, loaded, is about 45 tons.

These cars provide accommodation for fifty-six third-class passengers. The luggage compartment has a capacity of 340 cubic feet. They run with a trailer, sometimes with horse-boxes containing horses, sometimes with a loaded goods wagon.

They only stop, between two consecutive journeys, during the time necessary for taking in water.

One or two automotor cars are required for the service, according to line. There is no reserve car. When required, a trailer is added, or else a train with locomotive is run.

The automotor cars are not laid up more frequently than other stock and their use is considered to be economical.

The lines on which they run have a total length of about 22 miles. The gradients vary between 1 in 50 and 1 in 90.

Midland Railway. — The Midland Railway, which has also electrified a part of its system, owns thirteen steam automotor cars : four with the engine at the head of the car, and nine with the engine inside the car.

These automotor cars run with one or two trailers. There is a small luggage compartment. They accommodate fifty-five passengers, all of the same class, and each trailer takes fifty-four passengers.

The distance run per day varies greatly. No minimum duration of stop between two consecutive journeys is fixed.

The automotor cars are used separately on their respective lines (1); there is no reserve If necessary, ordinary trains with locomotives are substituted.

These trials have been begun too recently to make it as yet possible to give any information as to the economical value of this stock.

British Colonies. — Empire of India.

East Indian Railway. — This company owns one steam automotor car, which runs between Agra and Tindla (Delhi district); but when the Patna-Gya line is completed, it is intended to operate a service there with another automotor car, conjointly with mixed trains.

The automotor car, which is on bogies, contains one first-class compartment (for 6 passengers), one third-class compartment (for 68 passengers) and a luggage compartment.

There is no trailer and it is only used to supplement a mixed-train service. Its daily run is 97 miles.

At present, this is only an experiment begun too recently to have any opinion as to its value.

The car is sent every ten days to Tindla to be overhauled. While it is laid up, the service is operated by a train consisting of a first-second class composite, a third-class carriage and a luggage van.

North Western Railway. — A steam automotor car, on bogies, tare about 20 tons, makes each day four runs of 1 hour 17 minutes each (distance, 27 miles), on a minor line. There

---

(1) Trent and Stanton Gate; Derby and Wirksworth; Derby and Ripley; Derby and Melbourne; Hemel-Hempstead and Harpenden; St. Albans and Luton; Bedford and Hitchin; Bedford and Northampton; Sheffield and Doncaster; Sheffield and Barnsley.

is a driver and a fireman (1). The car will take five first-class, five second-class and seventy-two third-class passengers.

This is only used for a supplementary passenger service. If necessary, an ordinary locomotive is substituted. It is certain that this substitution involves additional expense. The car is more frequently laid up than the ordinary stock; yet if we compare the receipts and expenses per train-mile, the result does not appear unsatisfactory.

Madras and Southern Mahratta Railway. — As an experiment, three steam automotor cars are being run, but on a main line. Each takes eighty-four passengers and can haul one or at most two trailers, so that a whole train can take 204 passengers.

British Colonies. — South Africa.

Central South African Railways. — Automotor cars are already running on two sections of the main line. The subject is now under investigation as far as secondary lines are concerned, on which automotor cars are going to be used before long.

Italy.

State Railway. — The system does not include lines on which passenger traffic can be conveniently carried by automotor cars only. The latter are more frequently to be found on lines of medium importance, where they run in between trains hauled by locomotives.

One trial only had been made between Cecina and Volterra, but it had to be given up owing to the difficulties which arose in consequence of the quality of the feed-water, difficulties all the more marked as the automotor boilers generally work at a higher pressure than locomotive boilers.

Nevertheless the question of organizing passenger train services by means of automotor cars, exclusively, is again under examination, in other cases which seem more suitable.

The automotor cars always haul light trailers, the number varying from two to four. The average daily run varies between 90 and 120 kilometres (between 56 to 75 miles). The shortest time of stop between two consecutive journeys is thirty minutes.

As the automotor cars, particularly at first, required more careful and more frequent maintenance than other stock, it was advisable to have a sufficiently large reserve. The proportion may be estimated at about one fourth.

Generally speaking, the automotor cars require repair more frequently than locomotives. The difficulties arising from replacing them by ordinary stock have up to the present prevented the extensive use of such stock for the operation of secondary lines.

In conclusion, and until more complete results are obtained, it may be stated that a service of automotor cars only, taking into consideration the condition of the lines and the variations in the passenger traffic, is not suitable unless the conditions are exceptionally favourable.

---

(1) On this railway system, there are three men on the locomotive: a driver, a fireman and an assistant to handle the coal. The same is the case on the other railway systems in the Empire of India; but at present trials are being made of having on the light locomotives two men only, driver and fireman.

Although this information is incomplete and rather heterogeneous, it nevertheless conveys a distinct impression that automotor cars have not been so successful as was expected some years ago, when there was a feeling that one was in the presence of a new evolution in the organization of passenger trains on secondary lines.

Mr. Cornel de Tolnay, in the report which he presented at the Washington Session of the Congress (1), quotes the opinion of an expert on the subject (2), who had recommended the system of separating passenger and goods trains, on minor lines, and had expressed himself as follows : " In order that this system may not cause any financial loss to the undertaking, it is necessary for the traction system to be modified radically. The steam-locomotive must disappear from passenger trains." Mr. Cornel de Tolnay added, it is true, that he did not quite share this opinion, which was perhaps a little hard on the locomotive.

Mr. J. Rocca finishes his report, drawn up in July 1904 (3), as follows :

" We think that the true solution of the organization of a cheap service on lines which carry little traffic will be found in the proper use of suitable automotor cars."

The experience of the last five years shows that too much was certainly expected from these cars.

In 1905, the problem of the automotor cars was still in the hands of the rolling stock and locomotive departments of the railways, for matters were still in an experimental stage; only isolated units were running, and these had been started principally in order to ascertain the cost of their working and the technical value of their design. This part of the problem, which required all the ingenuity of technicians to the highest degree, can be regarded as solved by now; perhaps the excellence and the originality of the patterns worked out even contributed to the optimism with which automotor cars were regarded.

It must be remembered that the original project of operation included essentially small trains, of a minimum dead weight, with engines of low power, better suited than steam-locomotives to the tractive effort required; moreover, as far as possible not more than one man should be required for driving any such engine.

When considering a given small amount of traffic, it was evident that the engine could be very small, of such dimensions that it was necessary to have a larger vehicle to contain it. It was in this way that the first conception of the automotor car arose; the type so designed is very useful and very advantageous as compared with ordinary rolling stock.

But as soon as it became necessary to construct more powerful motors, which normally required several axles for their support, it becomes less apparent why the

combined form of the automotor car was retained, which was by no means one of the essential conditions of the proposed project. Such a combination, even if slightly reducing the dead weight, on the other hand involved many difficulties. In starting in this way, that is to say in taking as basis the type of the automotor car, it was necessary to get all the constituent parts of the motor into as small a space as possible; and this, in spite of the ingenuity of the devices invented, could not but result in making these parts more delicate, more difficult to handle and to maintain. Combining the two separate parts, the motor and the body of the carriage, into one, also necessarily increases the time the car is laid up, as whenever one requires repair the other can also not be used.

Attempts have been made to overcome this latter disadvantage by mounting the motors on interchangeable trucks, easy to detach from the body of the carriage; but this does not alter the fact that the coupling up cannot be effected with any vehicle, but only with one special type of body, designed for the purpose; so that the number of interchangeable units necessarily remains limited.

As a matter of fact, the information supplied shows that, as a rule, the automotor cars have to be laid up more frequently than ordinary rolling stock, for examination, cleaning and repairs.

But the same information shows that the most serious defect of the automotor cars is their want of flexibility; they are unable to meet, from day to day, the requirements of a varying traffic, and so it becomes frequently necessary to replace them by locomotives and ordinary carriages. That is a practical point which perhaps escaped attention at the start, and was not considered by designers who each worked out types suited to their theoretical traffic requirements, which were fixed and definite in character.

We cannot assume, as our hypothesis, that as soon as there is a certain amount of traffic or as soon as there are rather considerable variations on lines constructed and operated economically, there should be an increased circulation of small-capacity automotor cars, for the original conditions of construction and operation limit absolutely the number of units which can be run per day. One is then often forced to adopt cars of greater capacity, with motors carried on several axles, which in fact become comparable with light locomotives, and are in sundry respects inferior to the latter; thus the advantages of the best type of automotor car are lost. It may be incidentally remarked that with the speeds usually adopted on the lines which we are considering, it is not of much importance, from the point of view of tractive resistance, whether we have several vehicles coupled up together or whether we have them combined so as to form one large vehicle.

It is also to be noted that as regards certain types of automotor cars it was desired to be able to run in either direction, without any necessity for turning the car round at the end of its journey, but this turning can equally well be avoided with small locomotives; the difficulties of construction appear in fact even greater in the former case than in the latter.

*

Finally, as regards having one man only to drive the motors, this is certainly an advantage offered by petrol-motor cars; but these, leaving exceptional cases out of consideration, belong to the class of small units, not suitable for work on sections with but little traffic; and if steam automotor cars are in question, it is not evident why arrangements cannot be made, not only with automotor cars but also with light locomotives, to satisfy all requirements (1).

Taking it altogether, the utilization of automotor cars, in order to be definitely economic, necessitates, in the first place, the conveyance of a regular passenger traffic by means of such cars; secondly, it must not be necessary to have types of large capacity and high power, in which the advantages of the combined type of vehicle are more or less lost. If therefore, this utilization is to take place on one section only, the traffic must be inconsiderable and but little variable. If it is possible to run a certain number of automotor cars, for the purposes of a regular service, on a group of minor railways which are close together, the difficulties and expenses which result from a specialized stock then become less, for it is then possible, without undue increase of reserve, to have several units in addition to those running regularly, so as to be prepared if any of the latter are laid up, or if a sudden increase in the traffic makes it desirable to run extra trains; nevertheless it is necessary that on the sections considered, there should be not much passenger traffic and that that should be fairly regular at all times, so as to make it possible to use small units without increasing the number of daily runs, for the latter would not be compatible with economic operation (2). Now it must be recognized that these conditions but rarely obtain in the case of secondary lines owned by the administrations of main railways.

These administrations have most certainly taken all these conditions into consideration. Not one of them has neglected the question, and it could hardly have been otherwise, considering all the inducements offered. For not only was there the possibility of improving, without excessive cost, the passenger service on their minor lines, at a time when competition by motor cars on the highways was to be feared; but there were also the expected advantages (increase in the number of trains, the use of new stock instead of the old generally placed on the section with little traffic) which the public was continually crying for (3). The higher authorities, in the presence of such an evident progress, insisted at the same time that this progress should be utilized, and it is hardly necessary to add that builders promoted this

(1) We have even recorded the fact that the Hungarian State Railway owns some light locomotives which are driven by one man only, while on the other hand there are two men for driving the motor of automotor cars.

(2) This increase moreover quickly increases the cost of the train staff, however few this may amount to per train-unit.

(3) On certain automotor cars there were disagreable vibrations which did away with some of the comfort which was expected from the new vehicles, but this detail remained rather unnoticed; moreover an instinct of simple curiosity increased the public favour for automotor cars.

general advance of opinion, by producing remarkable and seductive patterns of cars.

It is not surprising that when such a current of opinion set in, all in one direction, the mark was occasionally overshot. Nevertheless, in many cases, it was decided to reject the system, without even making trials ; in other cases, one has gone beyond this, it would seem, and accepted certain results only with the object of going as much ahead with the matter as possible. As regards the managements of great railway systems, but few in number, who have instituted regular automotor car services on the sections where there is little traffic, it is to be noted that the first experiments have occasionally resulted in the utilization of automotor cars outside those sections, the majority recognize, in their answers, the more or less definite want of success of these attempts, and it appears indisputable that they will be all the less inclined to extend or generalize this system in the future, as the lines experimented with at the start, were evidently those where conditions were most favourable.

On the other hand, it would no doubt be desirable to examine the few answers which record that successful results have been obtained with automotor cars, in order to ascertain what the determinating factors of these results have been, and in order to obtain at least an approximate estimate of the financial results attained. These answers are however unfortunately not explicit on these points, and are limited to simple affirmations, so that it is not possible to proceed even to a summary analysis. But out of all the conclusions which we are able to draw from our investigations, there is to be remembered this fact of capital importance, that in spite of the ardent desire of the administrations of main railways to organize automotor services, the latter have in the end only been instituted on very few secondary lines, and that most of these attempts have by no means given very satisfactory results.

In truth the objection might be raised that as a large number of the main systems has during the last few years had to expend considerable sums on acquiring rolling stock for their main lines, they thought it inadvisable to order at the same time automotor stock for their local lines, the more so as their purchases resulted in leaving a quantity of the older rolling stock available for the purpose. But we do not think that this reason would have sufficed to restrain the administrations from at least making trials, if they could have expected, after the trials, those extensive economies which it was at first hoped would be realized by the use of automotors.

Finally, it may also be argued that better chances of success would result if the number of automotor services were increased, so that a greater number of interchangeable units would become available. But in spite of all this, the difficulties described would not disappear completely, and those which experiment has revealed are in themselves sufficiently serious to prevent, in our opinion, any larger extension of such services on the lines we are considering.

If in order to render our investigations more concrete, we limit them to the great French railway systems, we find that two of them, the Eastern and the Western (now forming part of the State system) have given up all trials of automotor cars,

although in the latter case, more especially, the number and condition of the lines with little traffic had been the subject of most careful attention, and every attempt had been continually made to apply all possible means of economical operation. The State and the Midi railways, after some experiments, not on secondary lines however, gave up the idea of automotor operation. The Northern Railway has made experiments of different kinds and is continuing them without having as yet arrived at any definite system; it is trying to adapt such a service to its suburban sections rather than to minor lines. Finally, there are only the Orleans and the Paris-Lyons-Mediterranean who after the first trials made with single units, determined to run regular automotor services on some of their lines with little traffic; although, strictly speaking, these are at present only really trials, but on a more extended scale than at first. They certainly have not succeeded in realizing, by the methods adopted, any indisputable advantage, and they do not express the intention of generalizing, or even of extending this system, which taking it altogether seems to be of very limited application, at all events as far as France is concerned.

It is also necessary to record, at the present time, a certain reaction; and several railway administrations show a tendency to adopt, for minor railways, rolling stock of the ordinary type, rather than automotor cars.

Thus we have seen that the Bavarian State Railway, while running some automotos cars on their main line, have tried to operate the lines of local interest by means of light trains, hauled by locomotives designed to be run by one man only. This administration has also just instituted, on a main line (Munich-Nuremberg), but for local traffic only, a new organization of trains with special rolling stock, and is has decided on locomotives and carriages designed for this special purpose.

We have also quoted the opinion of the French State Railway, which seems to prefer, in such cases, light locomotives to automotor cars.

It is, moreover, rather a rare thing for administrations of important railways to have to consider questions of this kind, for as a rule they use up their old stock on the secondary lines; and cases where conditions were otherwise have no doubt been exceptional during the last few years; more especially, as regards secondary railways, as what was more particularly attempted was a transformation of the passenger services by using automotor cars only.

The problem thus arises more frequently in the case of secondary systems, when new lines are opened to traffic. As the latter are outside the scope of our report, we have not subjected them to investigation, although the factors concerned are very similar when it is a question of using specialized stock for the service on a given line, no matter what railway system it may belong to.

We may however state that the tendency mentioned exists in these cases also, and that we know of several recent cases where secondary systems which had to acquire new rolling stock decided on light locomotives and carriages of the current type.

We must in fact recognize that the existing situation is very much the sams as it was before the recent experiments on the use of automotor cars on secondary rail-

ways. Are there now perhaps more cases in which automotor cars are superior, owing to the improvements made, when similar experiments have been made in the construction of light locomotives? It would be difficult to assert this, but in any case it is no longer possible to look on the use of automotor cars, for operating the service on lines with little traffic belonging to main railways, as a general solution, capable of revolutionizing the economic operation of such lines.

We may however remark that such a transformation, or at least a great extension of the limits inside which the use of automotor cars is advantageous, may result later on, on the other hand, if such lines are electrified; for it is readily seen that the objections against petrol or steam automotor cars disappear or are much reduced in the case of electric cars, where the motors occupy but little room while if necessary, being of great power; and such cars are easily driven by one single man, even if several units are joined together, as may be required. And this makes it also possible, on the other hand, not to multiply the individual runs per day on days on which there is a rush of traffic.

SUMMARY AND CONCLUSIONS.

At the 1905 Session of the Congress, the discussion on the simplified methods of operating lines with little traffic (then all these lines were included, whether belonging to a main railway or not) became concentrated exclusively on the conditions under which automotor cars could be used, and it cannot be doubted that it is that part of the question which alone led to the demand for an ultimate continuation of that discussion. Since then, as was to be foreseen, very few innovations have appeared, as regards such methods as a whole.

In most of the countries, the laws and regulations affecting secondary railways have not been altered; in some of them however, particularly in Germany and in Austria and Hungary, the working regulations of these railways have been improved, most frequently as regards their details.

Generally speaking, the administrations which have expressed any opinion on the subject, consider that the legislative provisions in force are sufficiently liberal. The railways of the United States of America, on the other hand, declare that the laws under which they work, while not establishing any distinction betweeen main lines and secondary lines, do not enable them to adopt on the latter lines any of the economic methods ordinarily used elsewhere.

The regulations issued since 1905 on the conditions and hours of work of the employees do not seem to have resulted in any alterations in the working methods which already existed.

As regards measures taken by the administrations themselves, recent regulations

have in Germany and in Austria and Hungary made possible some improvements and simplifications in the service on local railways. In other countries, one has nearly always been contented to continue existing methods, merely extending or limiting them in accordance with the variations in the importance of the traffic on certain sections.

We may however note, as having given rise to important applications :

The use of the telephone, which tends to replace the telegraph more and more, even for the transmission of orders referring to train movements;

The complete closing of small stations, during certain hours of the day;

The reduction, to a minimum of two men, of the number of employees on minor trains, measures being taken to enable one man to drive the engine.

It may be added that in spite of the attempts made to reduce the unit cost of small trains (light locomotives and carriages, automotor cars), the system of mixed trains is still recognized, in principle, as the most economic for the operation of local railways; in addition it makes it possible to accelerate the circulation of the goods stock.

As regards automotor cars, it is more particularly in this direction that the greatest efforts have been made to improve methods of operation on secondary lines. In spite of the investigations made and of the improvements introduced in the construction of such cars, only a few administrations of main railways have finally adopted a normal organization, at some points, of automotor cars or have even proceeded to make trials simply. Practice has shown that these cars give rise to rather serious difficulties in working, either by being frequently laid up for maintenance or repairs, or, and still more so, by their want of capacity when there is a rush of traffic.

When it is not possible to use such small units (and this is often the case on lines with little traffic), the advantages characterizing the combination vehicles are much reduced, and finally, sundry railway administrations tend today to prefer light locomotives, when they consider it advisable to form, on the sections in question, the passenger trains of special rolling stock.

In any case it appears certain that the use of automotor cars will not become extended, as a method of economic operation, on the many lines with little traffic belonging to the main railways, and that from this point of view such use will be limited to some of these lines only, where there is but little traffic, and where the amount of traffic varies but little during the year.

Taking all the preceding information into consideration, the sole conclusion which is for the moment apparent refers to this use of automotor cars. As regards the rest, as the state of affairs is very much the same as in 1905, we think it suffices to place this on record. We therefore propose the following conclusions :

Since the last session of the Congress, very few alterations have been made both in

the legislative provisions and in the methods of economic operation of lines belonging to main railways but carrying little traffic.

The attention of the railway administrations had been drawn specially to the use of automotor cars, and it was in this direction, in fact, that nearly all the researches for improving the service on these lines tended.

According to the experience which has now been obtained, this solution will not lead to a general transformation of this service, and it would seem that it can only be ranked among economic methods applicable to particular cases, when there is a combination of favourable conditions.

APPENDIX.

Detailed list of questions relating to question XVII.

I. — Legislative provisions.

1. Have there been enacted in your country since 1904 (the date when information of the same kind as that sought in the present list of questions was supplied for the last Congress), any laws or regulations regarding the simplification, on lines carrying little traffic but belonging to main lines, of the general rules regulating the operation of railways? If so, kindly communicate these provisions, drawing attention to how they differ from the previous legislative enactments.

2. Have any other laws or regulations — relating for instance to the conditions and hours of labour — had any appreciable effect on the previous methods of operating your lines with little traffic cheaply? If so, mention the alterations necessitated by these laws or regulations.

3. Are there any laws or regulations at present being drafted with a view to simplifying the operation of lines carrying little traffic belonging to main lines? If so, in what direction do the simplifications under consideration tend?

4. What improvement in the present legislative provisions seem to you advisable to increase the facilities and save expense in operating your lines with little traffic?

5. By what characteristic does the legislation in force recognize the secondary lines of your system? Does its character follow from a classification adopted beforehand; does it depend upon the number of the trains, their composition, their speed, the intervals between two consecutive trains in the same direction, a shuttle service, maximum mileage receipts, etc.?

II. — Actual methods followed in working lines with little traffic cheaply.

6. What modifications have been actually instituted since 1904, in working your lines with little traffic cheaply? Have you extended or curtailed your previous methods of cheap working? Have you introduced them on new lines? Have you, on the other hand, abolished them on lines where they were previously in existence?

7. Have you introduced on any of your lines with little traffic any new methods of cheap operation, affecting either operation properly so called, or the simplification of appliances (track, stations, signals, etc.)? In what do they consist?

8. Have you succeeded, in any instances, by separating your passenger service from that of slow goods, in reducing your operating expenses? Did not this organisation tend more towards an attempt to develop the traffic or was it really cheap in itself? Kindly explain the individual circumstances that made it possible to effect a saving.

9. Does not operation by mixed trains, utilizing the various trains in the day for working off goods wagons, result in-or is it not likely to result in-liberating the goods stock more rapidly?
If you have tried to derive this advantage, by using mixed trains, of a more rapid circulation of your goods wagons, what measures have you adopted to this end?

10. In a general way, have your methods of working lines with little traffic cheaply tended towards the more rapid circulation of the rolling stock? If so, state what advantages or losses result therefrom.

11. In the service of your lines with little traffic, do you make use of trains with a reduced complement of staff or vehicles? What are the accepted regulations on this point? Does such reduction extend to mixed trains? Is it current practice on your lines with light traffic; does it frequently happen or only in a few special cases?

12. When utilizing engine and car of the ordinary pattern (with or without minor alterations), have you succeeded in employing one man only on the engine? Under what circumstances has this practice been found feasible? What minor alterations especially have had to be introduced with this object upon the engine or car of the ordinary pattern?

13. If a train has accidentally to pull up between stations on a line with little traffic, have you simplified your ordinary regulations for its protection? If so, what special measures have been adopted in such a case, especially when the train staff has been reduced in number?

14. Do you use automotors on any of your lines with little traffic? Does this apply to isolated lines, *i. e.* operated separately by a small number of automotors, or to a group of lines connected to one another from the standpoint of their service by automotors and requiring altogether a fairly large stock of motor units?

15. What patterns of automotors are used? Seating accommodation for passengers of different classes, room for luggage or quick freight, mails, etc.?
Kindly furnish a rough plan to show the arrangement of these automotors.

16. Are the automotors used by themselves or with one or more trailers, normally or exceptionally? What is the maximum composition of a motor train (vehicles, seating accommodation, quantity of goods, etc.)?

17. In using automotors, how do you contrive, if need be, to convey certain quick freight traffic in definite separate wagons (coffins, live-stock, etc.)? Do not difficulties arise if such traffic offers itself?

18. What are the average (partial or complete) daily runs of the automotors in the various cases in which you use them? How long are the minimum compulsory stops between two consecutive journeys?

19. At places where you use automotors to serve lines with little traffic, what number do you find requisite for the normal service? How many do you keep in reserve, above and beyond this number?

20. How do you cope with extra traffic, either when expected and periodic (fairs, market days, festivals), or when unexpected or exceptional.

*

21. Are you not obliged more or lass frequently to substitute trains of the ordinary kind for automotors? Does not this result in inconveniences and expenditure which appreciably detract from the advantages arising from the use of automotors?

22. What is the average annual number of days that the automotors actually run and the number of days they are laid up for maintenance, repairs, substitution of an ordinary train for the automotor etc.? Are not these automotors more often laid up for maintenance or repairs than the ordinary rolling stock?

23. Taking into consideration the objections to the employment of special rolling stock, lying idle, substitution of ordinary rolling stock, etc., does the use of automotors appear to you on the whole economical in itself on lines with little traffic?

III. — Results obtained.

24. Selecting as instances any of your lines with little traffic upon which you have introduced cheap working and which appear to you of sufficient interest to mention, please say what results have been attained, giving figures in support of your statement as far as possible, and explain any peculiarities in plant, traffic or operation as regards these lines.

Please mention more especially, with a view to advantageous comparison :

a) the general features of the construction of the lines under consideration (length, gradients, curves, number of stations, halts or other stopping places, equipment of the various stopping places, passing places, gates and barriers at level crossings, signals, telegraph and telephone installations, alarm bells, etc.)

b) the general features of the traffic (quantity, in each direction, of passenger traffic and of slow and fast goods traffic, subdivided by sections if requisite — peculiarities of the traffic : variation, kinds of the bulk of the traffic, etc. — and distinguish if need be between the local and through traffic.)

c) simplifications adopted in operation, control of the service, specialisation of staff, general expenses, general service of stations and trains, employment of women or outsiders, leasing, daily number of trains in each direction, kind and composition of these trains, utilisation of special rolling stock, manner of issuing tickets, forwarding and receiving luggage and slow or fast goods, accounting, handling of money, maintenance and inspection of lines and buildings, etc.).

d) number of employees per kilometre of line, subdivided into classes.

e) extreme hours of service per day — trains and stations.

f) the amount and approximate value of the motive power and rolling stock, both of what is in regular use and in reserve, employed for the service of the line and set apart for this purpose (including only a portion of the value of these appliances if they are used simultaneously at other points).

g) as regards non-specialised rolling stock (*i. e.* doubtless all the slow goods stock, considering what lines are under consideration) the number of wagons coming each day upon the line, in times of ordinary traffic and at the time of the maximum amount of traffic, and the average period

during which these wagons remain on the line in each of the above seasons, the period being counted from the moment when a wagon reaches the junction station until it gets back to this station.

(Give separately, if need be, statements as regards local traffic and traffic in transit).

Indicate the value and load of the wagons usually employed in the service of the line.

h) the financial results :

Annual receipts, subdivided according to their nature : passengers, luggage and dogs, express goods, slow goods, extra receipts (subdivided also, if need be, into warehouse receipts and through conveyance receipts).

Annual expenses, subdivided, as far as possible, according to the various departments : management and general expenses, permanent way and buildings expenses, locomotive power and running expenses, station expenses and agency charges, etc.

(In expenditure on rolling stock, it will be necessary to exclude such as belong to the maintenance of rolling stock not specially kept for the service of the line.

SECTIONAL DISCUSSION

(3rd and 5th SECTIONS MEETING JOINTLY.)

Meeting held on 8 July 1910 (morning).

MR. DIETLER, PRESIDENT OF THE 3rd SECTION, IN THE CHAIR.

The President. (In French.) — The President of the 5th section having asked me to take the chair at this meeting, I call upon the reporter to give us a summary of his report.

Mr. Quarré, *reporter*. (In French.) — Gentlemen, before giving a summary of my report on question XVII, I wish to pay tribute to the memory of Joseph Rocca, reporter on the same question to the last session of the Congress, who was one of the victims of the earthquake which devastated Messina and Reggio in Calabria, on 28 December 1908. I was unable to do this when I drew up my report, as I was then ignorant of his tragic end which I only knew later.

In the August 1909 number of the *Bulletin of the Railway Congress* an obituary notice paid a just tribute of honour and regret to the memory of Rocca, in which I humbly wish to join.

I only had but too few opportunities, during journeys of inquiry in Italy, to meet Mr. Rocca, but they were enough to show me not only the extent of his professional knowledge but also his extreme affability and complaisance.

The members of the 3rd and 5th sections, especially those who knew the late Mr. Rocca, will understand why I have occupied a moment of their time in order to pay this posthumous homage to him. (*Approval.*)

The President. (In French.) — We all wish to join in the touching remarks which the reporter has just devoted to the memory of the late Mr. Rocca. (*Hear ! Hear !*)

Mr. Quarré, *reporter*. (In French.) — Gentlemen, the resumption of a discussion concerning the means of organizing a cheap service on a main railroad's branch lines which carry little traffic does not seem, under present conditions, to be of much interest, at least as far as most of those means are concerned.

At the last session of the Congress, that

is only five years ago, it already seemed that there was but little to discuss. In spite of two very full reports to the Congress, the discussion becomes at once limited *exclusively* to an exchange of views concerning the possibility of running automotor cars on more or less steep gradients.

There is no doubt that general attention was then drawn to the problem of the use of automotor cars on branch lines. That was what gave the question a revived interest and led to its retention in the agenda of the present session.

Thus this question, long considered, examined from every point of view, solved today as regards its main features, can only be reconsidered in two ways : either by a careful study of improvements made in details, or by a more general examination of the first results of some new system, of a kind to modify the conditions of the problem. Now a detailed analysis would only have been possible if the work had been divided among a number of different reporters, instead of having only one reporter for all countries. It is hence probable that the chief object in view was that part of the question concerning automotor cars whose utilization (apart from some few experiments made at earlier dates) was considered a new development, capable of modifying the operation of the traffic on branch lines.

Be that as it may, and given the state of the question, taking into consideration the reports presented in 1905, I thought it would suffice if I brought the reports presented to the last Congress up to date, and it was with this object in view that my inquiries were addressed to the managements of the main railroads.

As these inquiries were very extensive, I had not time to supplement them by making other investigations, direct, in the different countries, and my report is based nearly wholly on the information received in answer to my list of questions, incomplete though it may be.

The report naturally includes two chief divisions, namely legislation and methods of applying it, that is to say, firstly, the orders coming from the supreme authorities, which the railway administrations have to obey, and secondly the rules made by those administrations themselves.

We will begin by examining legislation.

The laws and regulations concerning the branch lines of main railroads have been modified, since 1905, only in very few countries, and in those the modifications have been but slight. I have only to mention the following :

In Germany and in Austria, the regulations affecting the operation of secondary lines have been modified, especially in Germany, with a view to the better coordination of the existing prescriptions, avoiding ambiguities. In both countries, the modifications which are of any importance do not affect fundamental principles, but only working details, allowing methods already known and used to be extended. In Italy, where a complete reform of the act of 20 March 1865, concerning railways, was expected, there were only some few modifications in the act of 9 June 1901, concerning the lines described as with " economic service ".

Finally, in England, as regards automotor services, the prescriptions referring to the construction of the track and of the buildings at stopping places between two stations have been made less strict.

On the other hand, the main railroad administrations who have expressed any opinion about the subject, have stated that they are generally satisfied with the laws and regulations applying to lines with little traffic.

Several administrations in the United States, however, think that the laws in force which make no distinction between main lines and secondary lines, do not give those facilities which are usually granted elsewhere.

Incidentally, I had asked whether other legislative enactments, for instance those affecting the conditions and hours of work, had not involved changes in the organization of the services. This does not seem to have been the case, in spite of the resulting increase in the cost of labour, which is considerable in some cases.

Thus from this first point of view, the opinion of a rather large number of railway administrations is that the legislation affecting secondary lines is today sufficiently liberal not to hamper the service unnecessarily. The experience acquired in this way makes it quite possible to draw up laws and regulations suited to lines with little traffic, and if some legislation is still too strict, this is certainly due to causes which are wholly of a non-technical order.

As regards the methods of applying the existing legislation, the answers show that the administrations of the main railroads have only made few and unimportant changes in their methods of operating secondary lines.

That was to be expected, the legislation having so to say hardly changed, and the authorized facilities being already in existence on the sections where it was considered advisable to apply them. Moreover, several administrations stated that their chief attention had been devoted, during the last few years, to their main lines. Finally, it cannot be denied that, as regards secondary lines, recent investigations nearly entirely had in view the use of automotors.

The following points are alone worth noticing :

The extension of the use of the telephone instead of the telegraph.

The complete closing of small stations at certain hours of the day so as to enable the proper observance of the regulations concerning the hours of labour, without employing any extra staff.

The continuation of the experiments made with a view to reducing the number of employees on small trains to two, the locomotive being driven by the driver alone.

These very interesting experiments have been made, either using special devices, as for instance the automatic firing of the engines or using the ordinary devices but arranging matters in every case so that the second employee can go on to the locomotive and help the driver if necessary. This system of having only the driver on the locomotive is as yet but little developed and many administrations hesitate to try it. It seems that this is a point about which valuable investigations can still be made.

Finally, on some railways, on the sections where there is little traffic, the system of keeping separate the goods trains and the passenger trains has been extended, less with a view to economize operation proper than with one to give the public a better service, without any corresponding

direct gain. The railway administrations recognize generally that in spite of the new methods adopted for reducing the cost of small trains per unit train, the system of mixed trains is as yet the most economic.

As regards the simplified methods of working, taking them altogether, it may be asserted that they are perfectly well known and sanctioned by sufficiently long use. Investigations having been carried out in all directions, these methods are sufficiently numerous and variegated that given suitable laws, one can always find one capable of satisfying the needs of the traffic at a minimum cost. It is beyond doubt that if the administration of a great railroad does not adopt such and such a method which is authorized by the regulations, this is not for want of consideration, but because it has not seemed to it to satisfy the requirements of the particular case in question.

Before passing to the consideration of automotors, I may remark that another division of my report might consider separately lines worked economically; but this division which followed that adopted in 1905 by Mr. Rocca, was only due to the special position, in Italy, of the lines with "economic service", as the legislation there only authorizes these working facilities if the number of trains is increased and the rates are lowered. Accordingly, this belonged rather to that part entitled "*Legislation*", in my report. But everywhere else it was a question, in the case of the lines worked economically, of the simplified system of working which consists of grouping together several secondary sections, giving them a special administrative organization, forming them, so to say, into one small railway system. That is in fact a method only applied among sundry other methods for the economical operation of lines with little traffic.

Moreover, the position of the "economic service" lines in Italy has remained very much the same since 1905, and as regards economically-operated lines in other countries, there are also very few recent applications of this method.

The examination of the utilization of automotors still remains. This examination is limited to lines belonging to main railways but carrying little traffic, leaving out of consideration, moreover, the technical questions relating to construction and operation included in question XII of the present Congress.

Some years ago, it was expected that there would be a great extension in the use of these vehicles on secondary lines. It was even expected that there would be an entire transformation in the service, due either to a great increase in the number of trains run per day, or to the complete separation, without incurring too great expense, of passenger trains and goods trains.

Mr. Rocca concluded his report as follows :

> We think that the true solution of the organization of a cheap service on lines which carry little traffic will be found in the proper use of suitable automotor cars.

In 1905, we were still in the experimental period. The units which were running served above all as experiments in order to determine the cost of working and the technical value of the design of the different types of cars. Considering the improvements since made by the de-

signers, that part of the problem may now be considered sufficiently solved.

During the last few years, such investigations have been made by all the administrations of great railroads. There is certainly not one which has not considered how to organize automotor-train services on sections with little traffic. Nevertheless most of these administrations have decided against them. Out of forty-three answers received about this point, thirty state that no automotor car is actually in use on their secondary lines. My report also contains other answers from administrations having automotors on some of their lines; it shows that generally speaking those automotor services are few in number and not much developed. Most of them, strictly speaking, are but experiments which are being continued, while the results are not yet sufficiently definite to make it advisable to extend this method of operating the traffic.

The only administrations which definitely state, without any special reservation, that they are satisfied with the adoption of a normal service of automotor cars are the following :

1° In Germany, the Wurtemberg railways.

However the automotor trains are nearly only *on main lines*. In the case of some branches, they can hardly be considered as more than continuations of main lines, when the continuation can easily be covered by the automotor train in its daily run.

We may note that of seven German railway managements which sent answers, six have no automotors on their lines.

2° In the United States, the Union Pacific Railroad.

It would have been very interesting to know the traffic conditions on the lines of that railroad, on which automotors are used, as well as the special conditions which made possible the excellent results obtained; the more so as of ten administrations in the United States which sent answers, the Union Pacific is the only one which has adopted this system. I have not been able to obtain any detailed information. The cars are of comparatively high power and run at high speeds; such do not *a priori* seem to be the usual conditions in the case of a local-line service.

3° In the United Kingdom, the Lancashire & Yorkshire Railway.

The use of automotor cars is however very limited, the company stating that the lines on which they run only have a total length of 22 miles.

I may add that out of six answers received from English companies, three only say that they use automotor cars. Two of the latter state, the first that the use of these cars does not seem to be very economical, and the second that the trials have been begun too recently to make it possible to form an opinion.

As against these few favourable answers, all the other administrations of great railroad systems which have automotors on their lines record the more or less marked failure of this system, or at least make reservations and do not feel inclined to extend it. The extension is all the less probable as the trials were no doubt begun on the sections most suitable for the experiment.

To begin with, nearly all the answers state that automotor cars require repair more frequently than the ordinary stock. This is not surprising, because, in the first place, we have in one lot both the engine

and the body of carriage; moreover, in designing such combination vehicles other troubles arise, especially from limiting as much as possible, the space the motor occupies. But according to those answers the most serious defect of automotor cars is their want of flexibility; they are unable to meet the day-by-day requirements of a varying traffic and hence it often becomes a necessity to substitute ordinary trains.

Mr. Rocca thought that once the automotor-car problem had been solved from the technical point of view, it would easily be solved from the commercial point of view. Now the experience of the last few years negatives this opinion. The branch lines of main railroads usually have such varying traffic that it is very difficult to deal with regularly by means of automotors.

These frequent replacements, which make it practically necessary always to have ordinary stock available, evidently much reduce the economic value of the new method.

Moreover, the great railroads nearly always have available, for use on their branch lines, stock withdrawn from use on their main lines, so that they do not need new stock for them. That is an important point which has to be considered when comparing the different methods of working. Moreover, any specialization of stock always involves a certain amount of trouble and expense, and this specialization is especially marked in the case of automotor cars, as it extends both to the engines and to the rolling stock.

However that may be, when the question has to be considered of buying new stock for use on a local line, there is at present a tendency in favour of light locomotives rather than automotor cars.

In any case, it certainly seems at present that the use of automotor cars, *on a main railroad's branch lines which carry little traffic*, is not profitable unless the traffic is very limited, and above all does not vary much during the course of the year. Now such conditions only exist in a small number of cases.

Finally, it is interesting to note that most of the previously-mentioned objections disappear or are much diminished if it is a question of electric automotor cars, and it may hence be hoped in the future, when the branch lines are electrified, to obtain with success those transformations in the service which appear difficult to realize under present conditions.

The remarks I have just made are based, as I have already explained, on the information which I received in answer to my list of questions, and on some other, but limited, information which I was able to obtain direct. This brings me to the following conclusions which I have the honour to submit to you:

Since the last session of the Congress, very few alterations have been made both in the legislative provisions and in the methods of economic operation of lines belonging to main railways but carrying little traffic.

The attention of the railway administrations had been drawn specially to the use of automotor cars, and it was in this direction, in fact, that nearly all the researches for improving the service on these lines tended.

According to the experience which has now been obtained, this solution will not lead to a general transformation of this service, and it would seem that it can only be ranked among economic methods applicable to particular cases, when there is a combination of favourable conditions. (*Hear! Hear!*)

The President. (In German.) — We will now proceed to the general discussion during which the different delegates can give us any information they have available, so that we may be able to consider the question from every point of view. After this general discussion, we will consider the conclusions given in Mr. Quarré's report.

Mr. Suarez had inscribed his name, but as he is not present, I call upon Mr. Campiglio to address the meeting.

Mr. Campiglio, Italian Union of local railways. (In French.) — Gentlemen, I think I can give you some information as regards the economic side of the question, about the trial of economic services made on the Italian railways

The trial was in the first place made on lines of the former Adriatic and Mediterranean systems. In accordance with certain special provisions of the law, the rates for conveyance were reduced and fixed stamp duty was changed into a *pro-rata* tax of 1·50 per cent.

The trial was made with reference to the changes required in the service with a view to making it easier: one class of passenger carriage was abolished, the classification of goods was simplified and there was a considerable reduction in passenger fares, a reduction amounting to about 45 per cent.

The favourable results obtained as regards passenger traffic, are to be attributed to the reduced fares and the increased number of trains. The number of passengers has doubled; in some cases it has even become sevenfold.

The trial was not, however, made general, on account of several reasons. In the first place, owing to the conditions of their contract with the government, the great railways had no interest in extending such services. In fact the addition of at least a couple of trains meant for them greater expenditure, not compensated by the gross receipts after the government tax had been deducted.

It is, however, true that in a general way, the economic service has been advantageous, especially to the public; but the latter has not always appreciated this. The new classification of goods gave rise to many complaints and the economic service was limited, after a certain time, to the passenger traffic.

As regards the reduction of passenger fares, this applied, practically speaking, only to the third class; hence it interested only people who previously had hardly considered the subject. Protests were made against the introduction of the economic service on certain lines where an ordinary service was operated.

It was thought that the economic service would lower the importance of the line.

As far as lines owned by private companies were concerned, the question assumed quite a different aspect.

An economic service could not be profitably introduced on them because the 5-centime ($^1/_2$ *d.*) stamp tax on each ticket would necessitate a great reduction in the rates, particularly in the case of short distance traffic.

The Apennine Central line had applied passenger rates similar to those in use on the great railways. But what happened? Although the number of passengers doubled, the receipts and expenses remained about the same and it was the government

which made a profit of about 14 per mil in consequence of increased receipts from stamps. Hence, the company did not benefit.

The conversion of the fixed tax into a *pro-rata* tax, desired by the private companies, met with much opposition from the government. It was only granted subject to a number of other conditions ; in particular the government shared in the increase in the receipts and in the increase in the number of trains of two classes.

The imposition of these conditions hampered and delayed the introduction of an economic service on privately-owned lines, for which concessions had been granted. As a consequence of this state of affairs, there are as yet no conclusive results worth mentioning.

I have just now received a telegram from Milan informing me that the chamber of deputies is considering the request that the fixed tax should be converted into a *pro-rata* tax.

It is accordingly to be hoped that the light railways will be able to make trials on a larger scale.

The President. (In German.) — Can Mr. de Burlet not give us some information about this subject?

Mr. de Burlet, Belgian National Suburban Railway. (In French.) — As you know, the Belgian National Suburban Railway Company only operates light railways and the trials it has up till now made with automotor cars, have not yet given any conclusive results.

A year ago, we started trying a benzo-electric car. The results seem rather favourable, but the trial has not yet been long enough to enable us to give you any definite information which might serve as guide.

Our company, in Belgium, is placed under very favourable conditions as regards the making of trials and we intend carrying them out on a larger scale. We have already ordered four cars of the same kind, which we shall put in service at the end of August on Brussels suburban lines, lines where there is a great deal of traffic, which are more of the nature of tramway lines. The motors will be powerful enough, we hope, to haul a second trailer or even a third, when there is a rush of traffic.

If among our colleagues here there are any who intend to visit the Brussels exhibition, it will be a great pleasure to me to show them those automotor cars in regular use.

Matters being as they are it is impossible, I again say, and in any case premature, to give now any definite information about the two essential points : the cost of fuel and the cost of maintenance. It will probably be possible to give this information at the next session, if the question is then on the agenda.

Mr. de Sousa, Portuguese State Railway. (In French.) — Gentlemen, I am going to give you some general information about the operation of lines with little traffic, included in our railway system, and also about the results obtained with automotor cars from the general point of view.

We operate, particularly in the south, lines in a country which is nearly wholly agricultural. The population is rather scattered and consequently we find a service of mixed trains to be the most satisfactory. They give us the greatest facili-

ties from the point of view of the goods traffic.

So far the operation of secondary lines has not yet all the flexibility desired. As a rule, the concessionaries are hampered by traditional and classical rules, which are satisfactory for main railroads, but which are rather troublesome to the concessionaries. Rather more facilities should be granted to them.

As regards automotor cars, the results obtained leave us undecided as to what opinion to form on this subject.

We have used cars with a steam motor on the Borsig system, with a motor bogie which could be detached from the car, so as to make it cheaper to repair the motor and make it possible to utilize the car better. These automotor cars can haul one or even two trailers if necessary. They serve more as an attraction to traffic. One is often troubled by the variations in the traffic. There is no sufficient opening. There is also the difficulty of running backwards, etc. It is difficult to obtain a satisfactory service under these conditions. There is also the question of the supervision of the track.

To sum up, automotor cars are only of limited use to us.

The President. (In German.) — It is satisfactory that several members wish to speak about this important subject. I now call upon Mr. Jaggard.

Mr. Jaggard, Pennsylvania Railroad. — I should like to ask a few questions with a view to getting a clear idea of the matter. It seems to me that European conditions are very different from American. First, as regards security : We, in the United States do not seem to have much option in the way of mitigating legislative requirements on railroads of feeble traffic. The federal authority called the Interstate Commerce commission, as well as the State commissions do not make much distinction as regards safety precautions, whether it be a large railroad, with important traffic, or a small railroad, with light traffic; thus the legislative demands are practically the same as regards automatic couplers, brakes, etc., for a small railroad a few miles in length as for the largest and most important lines. As regards signalling, the matter is not so fully developed, but the indications are of the same kind. For freight cars alone, there exist about six conditions that each vehicle must satisfy before it is a proper car to circulate on the railroads of the country. I should like to know how European authorities regard a mitigation of these conditions. Are you not afraid security may be affected thereby ?

Another question which I wish to ask relates to the facilities offered to the public. In America, almost every small farmer living on the line of a secondary railroad, demands first class service under all circumstances, however small may be the line, and how insignificant his traffic. If his wife wishes to go to a neighbouring town to make some trifling purchase she is anxious to have the same convenience, in the way of passenger train accommodation, as if she were traveling on a large railroad. If the farmer has hay to sell he demands the same attention for his small crop of hay as if he were one of the greatest shippers in the country. This picture is perhaps slightly exaggerated, but in the main is correct. This fact and the one already mentioned that there is no miti-

gation as to the requirement for safety are obviously a source of great difficulty for railroads. As I see it the situation is not the same in Europe, and I should like to know whether the people, who are badly served by these small railroads, are satisfied with the service less complete than on the other lines, both as regards safety and as regards facilities for shipping and traveling offered to the public.

Mr. René Jourdain, St. Quentin-Guise Railway, France. (In French.) — I think it useful to give some information, because during the last three years I have been comparing the results obtained with steam cars on a local line with those obtained with our old system of light trains hauled by small locomotives, on other lines. Now without wishing to prejudice automotor cars, oil cars for instance, which seem more like automobiles on rails, experience has proved this to me : the automotor car which we tried, in order to obey the dictates of fashion, which exists in the railway world as elsewhere, gave results which proved to us that this car had nearly all the disadvantages of the small locomotive or of the light train, without having any of its advantages. In the first place, owing to the very purposes the car is to be used for, the different details of the motor are placed close together and it is difficult to examine them; the dust of the road makes them wear and frequent renewal is necessary. In the case of small locomotives, even if light (10 to 12 tons), the parts are more accessible and upkeep is then much cheaper. Consequently, from the point of view of maintenance, the steam car is certainly inferior to the small locomotive.

From the point of view of the fuel, exactly the same is the case, for if one wishes to adopt, for instance, the system of feeding the grate continuously, all sorts of difficulties arise. It is necessary to use special and very expensive fuel, and thus the cost is increased without special advantage. It follows that the small locomotives weighing 10 to 12 tons, which can easily haul two or three passenger carriages together with a van to take goods, the latter being indispensable with us, make it possible not only to operate the passengers service with us, but also, what is also a necessity with us, to retain the mixed train; that little locomotive can do work which the automotor car is not equal to.

That is why, as far as we are concerned, we ask that automotor cars should be put away, and utilized only when one cannot do otherwise. It must be the general rule that they are replaced by small locomotives, which have given us every satisfaction for fifteen years. (*Applause.*)

The President. (In German.) — I now call upon Professor Ulbricht.

Mr. Ulbricht, Saxon State Railway. (In German.) — The point raised by Mr. Jaggard seems to me to deserve consideration and I will accordingly give some information about this point in the hope, however, that further information will be given by other members of the Congress. It is in fact a very important question to know whether secondary railways are to be treated, from the point of view of safety and of facilities, exactly like the ordinary lines of main railroads. I may say that in Germany secondary lines are required to give as many guarantees as

main lines. But the great difference is that the speed is less and that there are greater time intervals between trains. I think that taking these two points into consideration it is possible to graduate safety appliances, but the amount of safety to be attained must always be considered a constant. If the trains run at a lower speed and there are longer intervals between them, it is evidently possible to adopt simpler safety appliances, if only for reasons of an economic order. The great improvements made in safety appliances have only been of gradual growth. This has not been because their utility was not recognized sufficiently, but because the increase of speed, etc., made it necessary to strengthen the conditions of safety. As on secondary railways one is less advanced from this point of view, it is also possible to simplify the safety appliances. One can hence say : the safety measures necessary on a main railroad are not necessarily applicable to secondary lines.

The question of the facilities offered to the public is a particularly delicate one. It cannot be disputed that passengers wish to find on the secondary lines all the comforts they have become accustomed to on the main lines. Now it seems to me that one should absolutely oppose anything beyond what the real requirements of a smaller traffic justify. The comforts supplied by main lines for long journeys cannot be expected on small secondary lines. On the other hand, I do not think that one can refuse to give on those short journeys the comforts to be found for instance on good tramways. At the same time, one can have the advantage of simplifying the classes, that is to say, to adopt as soon as possible the principle of one class only, but suitably and nicely arranged. In this way, the economic needs of such a secondary line can be met rationally. I should like to hear, as I have already stated, what the members of this meeting think about this point.

Mr. Machowetz, Austrian State Railway. (In German.) — Automotor cars have been in use since 1904 on the lines of the Austrian State Railway, namely one Daimler petrol car, one Serpollet steam car and four Komarek steam cars. In the earlier years, very unfavourable results were obtained with those automotor cars as the design of the motors left much to be desired. The cars were more frequently at the repair shops than on the line, and the consequent temporary use of locomotives involved a large expense. Some time ago, the Komarek cars were much improved, and such are now in use. But we cannot yet give any definitive opinion whether it is more profitable to use light locomotives than automotor cars. In any case, the conclusion seems probable that the use of automotor cars on the State Railway will not become extended.

The President. (In German.) — Light lines have developed to an exceptional extent in Wurtemberg, Bavaria and Prussia. Perhaps a delegate from those countries can kindly give us some information about this subject which is of great economic interest.

Colonel Suarez, who inscribed his name at the beginning of the discussion, is not present. Is there any other member who wishes to speak in the general discussion?

Mr. Kareischa, ministry of ways of communication, Russia. (In French.) —

I should like to say a few words in answer to Mr. Jaggard.

In Russia, there are technical working regulations which all lines must observe. In the case of local lines however the minister of ways of communication has the right to modify these rules in a liberal direction.

The principle is the same as in Germany.

Mr. Maresch, Rumanian State Railway. (In French.) — The safety measures must be proportioned to the speed.

Mr. Quarré, *reporter*. (In French.) — There is another interesting question to be examined, that of reducing the staff on the train, the driver being alone on the locomotive. Can nobody give any information about this point?

Mr. Ulbricht. (In German.) — I can give some information about what we are doing in Saxony. The question of having a driver only on the locomotives on the secondary lines is still under investigation. The system has been adopted experimentally and as yet no appreciable disadvantage has become apparent; the conductor of the train is expected to help the driver on the way when he has not to attend to his own proper duties. Thus there are two men on the locomotive while running, but when starting and at the moment the train arrives at a station, there is only one. I am speaking for the moment of small steam locomotives. If electric traction is adopted, whether the ordinary trolly system or the accumulator system, it is possible to arrange matters — as I know has been done in Prussia — so as to make it easier to have only one driver on the automotor car; the current only passes as long as the driver holds the handle of the controller, so that in case of any moral or physical collapse of the driver the car stops. But I think that this organization can at present only be considered an experimental one and it is not yet possible to give a definite decision about this question of single driving.

Mr. Waechter, of the « Vering & Waechter » Company, Germany. (In German.) — In the grand-duchy of Baden, having one driver alone is authorized on lines with little traffic if the line is wholly laid, or at least nearly so, on an independent road-bed and if the cab of the driver is accessible to the other man on the train. The latter must know enough about driving the engine to enable him to stop the train.

Mr. Machowetz. (In German.) — In Austria, on the Prague-Cercan-Dobrzisch line, an automotor car is running on which there is one driver alone, but the conductor must understand the working of the motor sufficiently well to be able to help him. As a rule, we prefer to have a crew of two men because the attention of the motor-man is so much occupied in watching the track that he cannot drive unless helped by a second man.

Mr. Serani, Italian State Railway. (In Italian.) — The problem of the staff on the engine is solved in Italy on certain lines which are operated electrically (lines with much traffic). I may mention the Milan-Varese line and the Valteline lines. There there are electric locomotives driven by a single driver, the motor-man, assisted however by the train conductor who must know how to stop the locomotive or auto-

motor car and who is authorized to do so in case of necessity, for instance if the driver becomes ill.

The President. (In German.) — Does the reporter wish to add anything?

Mr. Quarré. (In French.) — No, sir.

The President. (In French.) — If nobody else wishes to speak, I declare the general discussion closed.

We now proceed to discuss the conclusions. There are three clauses.

The first clause is :

" Since the last session of the Congress, very few alterations have been made both in the legislative provisions and in the methods of economic operation of lines belonging to main railways but carrying little traffic. "

— Adopted.

The President. (In French.) — The second clause runs as follows :

" The attention of the railway administrations had been drawn specially to the use of automotor cars, and it was in this direction, in fact, that nearly all the researches for improving the service on these lines tended."

Mr. René Jourdain. (In French.) — It seems to me that the end of this clause is rather exaggerated; researches for improvements have evidently been made in many other directions. It would be better to say : " ... that a great part of the researches for improving..."

Mr. Quarré. (In French.) — I only speak of what has been done during the last five years. Now according to the information I have received, there have been very few changes during that time. It follows on the first clause which runs : " Since the last session of the Congress, etc.". Nearly all researches for improving the service, as regards the lines which we are considering here, have been in the direction of the utilization of automotor cars.

The President. (In French.) — The first part of the clause is not disputed : " The attention of the railway administrations had been drawn specially to the use of automotor cars."

The reporter then continues as follows : " and it was in this direction, in fact, that many of the researches tended, etc. "

I do not know whether the reporter can assert this so absolutely. Mr. Jourdain asks us to say " ... a great part of the researches..."

Mr. Quarré. (In French.) — We might say : " It is in this direction that since that date (namely the date of the last session of the Congress) nearly all the researches, etc. "

Mr. René Jourdain. (In French.) — It would be enough to say " ... a great part of the researches..."

Mr. Quarré. (In French.) — I do not quite see what else has been done during the last five years to modify the methods of economic operation belonging to main railways but having not much traffic.

The President. (In French.) — Does Mr. Jourdain uphold his proposal?

Mr. René Jourdain. (In French.) — The reporter mentions in his report the substitution of the telephone for the telegraph, which is an important modification; also the complete closing of small stations at

certain hours of the day, a practice which now exists on almost all the French lines of local interest; also the reduction in the train staff, etc. It accordingly seems that the very report itself contradicts the words " ... nearly all the researches..." in those parts in which the reporter mentions other interesting modifications.

Be that as it may, seeing the explanations of the reporter who declares that these words only apply to one particular question, I do not press the point.

Mr. Quarré. (In French.) — I do not oppose that we should say " ... it was in this direction that most of the researches..." instead of " ... nearly all the researches..."

I must however remark that it follows from all the answers I received, that the researches nearly all concerned the use of motor cars. Very few administrations have considered the other measures (use of telephones, closing of stations, etc.) which I have mentioned in my report.

Mr. René Jourdain. (In French.) — The use of the telephone, the closing of stations, etc., have been adopted generally or nearly all minor lines and the application of these measures has resulted in considerable simplification.

Mr. Quarré. (In French.) — Do you refer to the lines belonging to main railways but having not much traffic?

Mr. René Jourdain. (In French.) — No.

Mr. Quarré. (In French.) — Those are, however, the only lines which we have to consider.

Mr. Leverve, Orleans Railway. (In French.) — There is yet another improvement which should be mentioned, an important improvement which one has tried and still is trying to introduce from the point of view of the traction on small lines. I mean the use of small locomotives with a one-man crew. Several administrations have not been much satisfied with the results obtained with automotor cars and have tried to solve the problem by using small locomotives. They hope in this way to effect the saving obtained in the case of automotor cars; they even are thinking of transforming their old locomotives.

It would therefore be advisable to add that the trials made with automotor cars have not given any very conclusive results, taking them as a whole; and that the researches are being continued in the direction of the use of small locomotives.

It would in fact be a mistake to assert that all the researches were with a view to the use of automotor cars.

Be that as it may, researches were made in both directions and it is possible to think that the solution of the problem will be found in the use of small locomotives rather than in that of automotor cars.

The conclusion, worded as it is, conveys that the automotor cars have given no result and that nothing is to be done in this direction. That is not my opinion.

Mr. Dounine, Vladicaucasus Railway, Russia. (In French.) — During the last few years much interest has been taken in Russia in light railways. Nearly all the researches have been in the direction indicated by Mr. Jourdain. The station service has been simplified so as to save a large number of employees.

Mr. Jaggard. — I agree with the dele-

gates, who find' inexact the term " almost all "; it does not apply to American conditions where numerous attempts have been made in other directions to realize more economical methods of railroad operation. We have made many trials with the telephone for train dispatching and have much confidence in this system; moreover, we have made a great many trials with a view to obtaining and adopting more substantial rails, also different systems of signalling, with a view to obtaining uniformity and simplicity.

Finally, we have experimented with cross-ties of different kinds, among others, ties treated with creosote, by different processus, in order to prolong the life of the tie. The Union Pacific Railroad in particular has made a great many trials with electric motors, but as a rule, upon most of the railroads the object of economy has been pursued by trials in other directions. I have just mentioned some of these.

The President. (In French.) — Mr. Jaggard thinks that the second clause of the conclusions should be struck out and Mr. Leverve proposes that it should not be stated in an absolute manner that all the researches concerned the use of locomotives, but that they also concerned the use of small locomotives.

Mr. Quarré. (In French.) — I mention in my report that sixty-eight administrations, of the one hundred and fifty-two consulted by me, answered that there was nothing new to report and that very few researches had been made concerning the use of small locomotives or of automotor cars.

On the other hand, as regards the reduction of the staff, the driving of the train by one single man, etc., I have mentioned all the answers and in particular that made by the Orleans Railway, which runs as follows :

> The system is not yet used, but the methods of applying it are being investigated.

Be that as it may, I do not oppose, as I have already stated, that the words " ... nearly all the researches..." should be replaced by " ... most of the researches...", although the answers I received lead rather tot he wording " ... nearly all the researches..."

As regards the subject of having a smaller train crew, that could be made the subject of a separate clause in the conclusions.

The President. (In French.) — In the first place, I wish to remark that Mr. Quarré feels disposed to meet Mr. Jourdain's view by accepting his proposal that the words " ... nearly all the researches..." should be replaced by " ... many of the researches."

The question now remains whether you wish to retain this clause or whether you prefer to strike it out. I should like to add that in my opinion Mr. Jaggard's remarks also concern other points of operation, which have also been considered by the European administrations, but do not affect the clause we are at present considering; for that clause refers in particular to the traction and not to the signalling or other services.

Mr. Quarré. (In French.) — Indeed, it also refers to the other services.

The President. (In French.) — If anything is to be added, it would suffice to say : " In Europe ". The reporter stated that

he received no answers from America. Consequently, it is evident that the conclusion he proposes cannot concern America, but only Europe. I would ask the reporter whether he consents to the addition of these words.

Instead of striking out the second clause, it is a question of ascertaining whether it is advisable to make an addition by virtue of which the statement is limited to Europe.

Mr. Quarré. (In French.) — I have given the answers of the American railways which show that in the United States the laws and regulations affecting secondary railways are excessively strict, so as to increase the cost of the service unnecessarily; this prevents the adoption of any economic measures. Accordingly, it seemed to me that but little had been done to improve this service. Complaints are made that no facilities are possible, in consequence of the very regulations themselves.

The President. (In German.) — Do you adopt the addition proposed by Mr. Jaggard, that these researches were in Europe? (*Signs of approval.*)

This addition is accordingly adopted, and under these conditions the proposal for striking out the clause falls to the ground.

If nobody makes any further proposals, I declare that clause 2, worded as follows, is adopted :

" The attention of European railway administrations had been drawn specially to the use of automotor cars, and it was in this direction, in fact, that many of the researches for improving the service on these lines tended."

There is still clause 3, which runs as follows :

" According to the experience which has now been obtained, this solution will not lead to a general transformation of this service, and it would seem that it can only be ranked among economic methods applicable to particular cases, when there is a combination of favourable conditions. "

Mr. Francis Level, Anvin-Calais Railway, France. (In French.) — At page 38 of the report (1), it is stated :

It may be added that in spite of the attempts made to reduce the unit cost of small trains (light locomotives and carriages, automotor cars), the system of mixed trains is still recognized, in principle, as the most economic for the operation of local railways; in addition it makes it possible to accelerate the circulation of the goods stock.

We should all agree, I think, to this statement. Does the reporter see any disadvantage in including it among the conclusions? I propose to insert after the words " of this service ", the following : " nor to the elimination of mixed trains ".

Mr. Quarré. (In French.) — The railway administrations have always been trying to find means for keeping separate passenger trains and goods trains; nevertheless one tries to content the public, as this has indirect advantages. It would hence be regrettable to show a tendency in favour of mixed trains, which on the contrary it is desirable to ged rid of. That is why I have not mentioned them.

---

(1) See also *Bulletin of the Railway Congress*, November, 1909, p. 1372.

Mr. de Burlet. (In French.) — You however praise them in that part of the report which is headed " Summary and Conclusions." One cannot think of eliminating mixed trains on economic lines generally.

Mr. Quarré. (In French.) — Certain administrations have tried to achieve such a separation, but as yet it does not seem that any saving has been effected. The system of mixed trains remains, in many cases, the most economic, but must we record this in our conclusions when our aim is the desirable separation of the passenger service and the goods service? That is the whole question.

The President. (In French.) — Does Mr. Level propose a definite text? If so, I request him to hand the bureau a proposal which can be put to the vote.

Mr. Serani. (In Italian.) — We are here considering lines having not much traffic or even very little traffic, on which mixed trains already exist. I think it is not advisable, from the point of view of economy, to propose to recommend the separation of the passenger service and the goods service.

The President. (In German.) — Mr. Level's proposal is opposed by Mr. Quarré. Now we have to arrive at a conclusion unanimously in order to submit it to the general meeting.

Hence, it seems to me advisable that Mr. Level should withdraw his proposal, the more so as the point is discussed in the report itself.

On the other hand, the Congress cannot adopt any conclusion which could, in some way or other, hamper the full freedom of the administrations to act in accordance with what special circumstances may arise.

Under these conditions, I think it would be best to adopt the original wording as it stands.

— Adopted (1).

The President. (In French.) — Does anybody wish to make any further proposal?

Mr. Leverve. (In French.) — I propose the addition of a clause to cover the point I have already raised, namely that not only have automotor trials been made, but also other researches which should be continued by the different administrations and which it is advisable to note. Accordingly I propose that the following clause should be added to the conclusions :

" It is desirable to continue the experiments made in order to obtain, by the use of small locomotives, either specially designed, or only modified, the advantages expected from motor cars, especially having one man only to drive the train."

That means to say, that as automotor cars have not given satisfactory results, at least to many administrations, there are other means of obtaining the same advantages as those expected from motor cars, namely a quick service and economy. There are in particular, I repeat, small locomotives either specially designed or only modified. Let us therefore mention this desideratum and the investigations made with this object in view.

(1) As shown below, the section reconsidered this vote and the addition proposed by Mr. Level was adopted.

Mr. Ulbricht. (In German.) — If this clause is adopted, I propose that it should be modified, that it should not mention the driving of the train by a single man, but only state : " the simplified driving ". Otherwise the wording would seem to me to be too narrow.

Mr. Machowetz. (In German.) — It is certain that the adoption of the principle of one man only on the locomotives on local lines would be advantageous as regards the reduction of working expenses. I think it would be advisable to have in the conclusions some mention of the advisability of continuing the investigation of the question of single-man driving. No doubt this system involves certain disadvantages what I have already mentioned. On lines where there are many level crossings without gates, or sharp curves, or sections where the outlook is limited, it is necessary for the driver to watch the track much more carefully. I will also ask what is to happen in case of sudden illness of the driver. In the case of single driving, the train would then continue to run on without being looked after. That is evidently a perilous case which requires consideration.

The President. (In French.) — I may remark that the question whether the engine can be driven by one man or two men has already been discussed. All that we can do, is to draw attention to the possibility of having a smaller locomotive crew.

Mr. Leverve. (In French.) — In order to meet the objection raised, one might say : " It is desirable to continue the experiments made in order to obtain, by the use of small locomotives, either specially designed or only modified, the advantages and the simplified driving expected from motor-cars."

This wish by no means implies the obligation of having one man only on the locomotive; it is self-evident that in many cases two men are required. But when it is a question of a simple service — as on many of the minor lines in France — it is possible to reduce the locomotive crew to one man.

The President. (In German.) — Will you kindly decide about the last proposal, definitely worded as it now is; does it meet with your approval, yes or no?

Mr. Quarré. (In French.) — The point seems to me at present a much-disputed one and as yet very few experiments have been made. Such being the case, would it not be simpler to omit it in the conclusions?

The administrations of the main railroads, in fact, are not making many trials concerning the use of small locomotives. On the other hand, the automotor cars are not designed specially to be driven by one single man; generally there are two men.

Mr. Ulbricht. (In German.) — For reasons of convenience, I recommend that the words " having one man only to drive " should be omitted, as several administrations are hostile to this system, and their hostility is perhaps justified. I would rather support the more elastic wording which I have proposed, which does not suggest the discontinuation of the investigation of the question of one-man driving, and in which the words " driving by a single man " are replaced by " simplified

driving ". I agree to all the rest of the wording.

The President. (In French.) — It is accordingly agreed that the administrations should be recommended to continue the experiments made in order to obtain, by the use of small locomotives or of modified locomotives, the advantages and the simplified driving expected from automotor cars. (*Approval.*)

Mr. Machowetz. (In German.) — I prefer the words " driving by a single man " to be retained, for they express the idea, intended by that wording, that a man can be saved, and if some administrations are hostile to this system, that is no reason for casting aside the question of making experiments. That is why I propose that the words " driving by a single man " shall be retained. In this way, we express exactly what we want.

The President. (In German.) — I would remark to Mr. Machowetz that such proposals only delay us. A little time ago this addition was rejected, and it was my impression that the section did not wish to open the question of the preference to be given to driving by a single man or driving by two men, and does not wish to recommend either the one or the other system. It is exactly for this reason that Mr. Ulbricht proposed a wording which is a little more general. The report is in everybody's hands and one knows in what directions simplification can be sought. But I think it would be difficult to come to an agreement if we specially mentioned driving by a single man. That is my general impression.

Mr. Machowetz. (In German.) — I simply thought that the direct statement " driving by a single man " would make the text more intelligible. But in the interests of simplicity, I withdraw it.

The President. (In German.) — Mr. Machowetz states that he agrees.

It is self-evident that it will be mentioned in the minutes that the simplified driving of the locomotives refers above all to reducing the locomotive crew from two men to one man.

After the explanations which have just been made, the section is unanimous in adopting Mr. Leverve's proposal, worded as follows :

" It is desirable to continue the experiments made in order to obtain, by the use of small locomotives, either specially designed or only modified, the advantages and the simplified driving expected from motor-cars."

— Adopted.

Mr. Maresch. (In French.) — I request permission to reconsider a detail in connection with the third clause.

Mr. Serani, in agreement with the French delegates, observed some little time ago that on lines with little traffic mixed trains were already in existence. He added that in his opinion the separation of the passenger service and the goods service was not advisable from the point of view of economy.

I hence request the section kindly to reconsider its vote, and I propose the adoption of Mr. Level's wording, which is as follows :

" According to the experience which has now been obtained, this solution will

lead neither to a general transformation of this service, nor to the elimination of mixed trains."

Everybody agrees to the statement that mixed trains already exist on lines with little traffic.

Mr. Quarré. (In French.) — It is said that " this solution will lead to neither the transformation of this service ". That implies that it will not lead to the elimination of mixed trains. The amendment hence seems to me to be unnecessary.

The President. (In French.) — It is agreed that clause 3 shall be worded as follows :

" According to the experience which has now been obtained, this solution will lead neither to a general transformation of this service, nor to the elimination of mixed trains, etc."

From all sides. — Yes, yes!

The President. (In French.) — That is accordingly adopted.

DISCUSSION AT THE GENERAL MEETING

Meeting held on 15 July 1910 (morning).

Mr. P. WEISSENBACH, PRESIDENT, IN THE CHAIR.

GENERAL SECRETARY : Mr. L. WEISSENBRUCH.

FIRST ASSISTANT GENERAL SECRETARY : Mr. MÜRSET.

SECOND ASSISTANT GENERAL SECRETARY : Dr. A. BONZON.

Mr. Dietler, *president of the 3rd section*, read the

Report of the 3rd and 5th sections meeting jointly.

(See *Journal de la huitième session*, No. 7, p. 7.)

" Mr. QUARRÉ (*reporter*) referred to the sad death of Mr. J. Rocca, reporter at the last session of the Congress, who had perished in the disaster at Messina. The meeting joined in the regrets expressed by Mr. Quarré. The reporter then mentioned that the subject of simplifying the operation of lines with light traffic had been frequently considered by the Congress. It did not seem that any new solutions had appeared since 1905.

" In his report, Mr. Quarré examined in succession the legislation and the application of measures suggested for facilitating the services on lines with light traffic, and he noted that hardly any changes had to be recorded. He then read the conclusions which he had drawn from the information received :

" Since the last session of the Congress, very few alterations have been made both in the legislative provisions and in the methods of economic operation of lines belonging to main railways but carrying little traffic.

" The attention of the railway administrations had been drawn specially to the use of automotor cars, and it was in this direction, in fact, that nearly all the researches for improving the service on these lines tended.

" According to the experience which has now been obtained, this solution will not lead to a general transformation of this service, and it would seem that it can only be ranked among economic methods applicable to particular cases, when there is a combination of favourable conditions."

" Mr. Campiglio (*Italian local railway Union*) described the experiments made on certain Adriatic and Mediterranean lines, by reducing the rates and simplifying the luggage service. The numbers of passengers had increased, but not the receipts, and the stamp duties had added to the State funds.

" Mr. de Burlet (*Belgian National Suburban Railway Company*) had during the last year been making trials with a petrol-electric car. They appeared to be satisfactory and his administration had ordered four cars of the same kind. He was of opinion that the question should again be placed on the agenda of the next session. It was probable that it would then be possible to give interesting particulars about the use of these cars.

" Mr. de Souza (*Portuguese State Railway*) stated that in Portugal the secondary lines were subjected to the same rules as the main lines. Cars with a steam motor on a separate bogie had been tried in order to develop the traffic on certain lines; but this system had proved inadequate.

" Mr. Jaggard (*Pennsylvania Railroad*) stated that conditions in America seemed different from those in Europe, as regarded facilities granted to secondary lines. In America there is no difference in the conditions. The requisite safety regulations are the same in the case of lines with light traffic as for the others. The public, on the other hand, asked for as many facilities on secondary lines as on the others, which results in unjustifiable expenditure.

" Mr. René Jourdain (*St. Quentin-Guise Railway, France*) stated that trials made with motor cars had not given results satisfactory from the economic point of view. Light-trains with locomotives weighing 10 to 12 tons were to be preferred.

" Mr. Ulbricht (*Saxon State Railway*) said that German legislation favoured secondary railways. Safety regulations were fixed according to the speed and density of traffic. As regarded facilities provided, these had at least to meet needs; but it could not be asked that they should be the same as those required in the case of main lines.

" Mr. Machowetz (*Austrian State Railway*) spoke about the Daimler, Serpollet and Komarek systems, which probably would not become applied more extensively, as the results had not been encouraging.

" Mr. Maresch (*Rumanian State Railway*) also expressed the opinion that the safety regulations should have to bear a relation to the speed.

" Mr. Quarré asked whether any one could give information about experiments with a view to diminishing the locomotive crews.

" Mr. Ulbricht stated that it had been tried, in Saxony, to have only one man on the locomotive, subject to the condition that the conductor should be able to stop the train, if anything happened to the driver. It was stated that a system of electric cars had been proposed and was being studied in Prussia, in which the train was stopped automatically as soon as the driver released the controller handle.

" Mr. Waechter (*Vering and Waechter Company, Germany*) stated that in Baden the locomotive could be driven by a single

man, if the line was on a separate roadbed and if there was intercommunication.

" Mr. Machowetz said that in Austria the conductor had to be able to stop the train if the engine was driven by one man only. But this system was not to be recommended in the case of a difficult line.

" Mr. Serani (*Italian State Railway*) stated that in Italy, on the Valteline and Milan-Varese main lines, with electric traction, there was only one driver; but the conductor had to know how to stop the train.

" The section then began to discuss the conclusions. With regard to the second clause, Mr. René Jourdain asked that the words " that nearly all the researches " should be replaced by the words " many of the researches ". He reminded the meeting that the reporter had also indicated other improvements, telephones, the closing of stations, etc., which had also been considered.

" Mr. Leverve (*Orleans Railway*) added that the reduction of the staff on the locomotives had also been tried as an economic measure.

" Mr. Dounine (*Vladicaucasus Railway, Russia*) stated that a saving could also be effected by simplifying the station services.

" Mr. Jaggard mentioned that in America economies had been attempted in the signalling system by substituting telephones for telegraphs, and by simplifying the construction of the track. He considered that clause 2° did not apply to the experiments made in America. He asked that it should be stated that this only referred to Europe.

" Mr. Francis Level (*Anvin-Calais Railway, France*) asked that it should be stated that " this solution will lead neither to... nor to the elimination of mixed trains ".

" Messrs. Maresch and Serani supported this amendment and remarked that in the case of lines with light traffic it was not economically advisable to have the goods and passenger services separate.

" — This amendment was adopted.

" Mr. Leverve proposed that the following additional clause should be added : " It is desirable to continue the experiments made in order to obtain, by the use of small locomotives, either specially designed, or only modified, the advantages and the simplified driving expected from motor-cars."

" Mr. Machowetz asked that it should be explicitly stated that it was desired to restrict the staff on the locomotive to a single driver on the lines with light traffic.

" The President remarked that the wording proposed did not exclude the application of Mr. Machowetz's idea.

" Mr. Leverve's proposal was adopted and added as clause 4°.

" The sections then agreed to submit the following conclusions to the general meeting."

The President. — The following are the

CONCLUSIONS.

" 1° Since the last session of the Con-
" gress, very few alterations have been
" made both in the legislative provisions
" and in the methods of economic opera-

" tion of lines belonging to main rail-
" ways but carrying little traffic.

" 2° The attention of European railway
" administrations had been drawn spe-
" cially to the use of automotor cars, and
" it was in this direction, in fact, that
" many of the researches for improving
" the service on these lines tended.

" 3° According to the experience which
" has now been obtained, this solution
" will lead neither to a general trans-
" formation of this service, nor to the
" elimination of mixed trains; and it
" would seem that it can only be ranked
" among economic methods applicable to
" particular cases, when there is a com-
" bination of favourable circumstances.

" 4° It is desirable to continue the ex-
" periments made in order to obtain, by
" the use of small locomotives, either
" specially designed or only modified,
" the advantages and the simplified driv-
" ing expected from motor-cars."

— These conclusions were confirmed by the general meeting.

SECTION V : LIGHT RAILWAYS

[625 .611] QUESTION XVIII

THE WORKING OF LIGHT RAILWAYS

Examination of the results of the different systems used in operating light railways (leasing, operating jointly with corresponding main railway, working by concessionary himself, with or without guarantee or subvention from the authorities granting the concession).

Reporter :

All countries. — Mr. Plocq, traffic engineer in chief to the Somme and Northern railways of the French General Light Railway Company.

REPORT

By Mr. PLOCQ,

INGÉNIEUR CHEF DE L'EXPLOITATION
DES RÉSEAUX DE LA SOMME ET DU NORD DE LA SOCIÉTÉ GÉNÉRALE DES CHEMINS DE FER ÉCONOMIQUES FRANÇAIS.

The Permanent Commission of the Railway Congress has intrusted me with the mission of examining the results given by the different systems used in operating light railways.

These systems depend to some extent on the legislation in force. This question of the legislation was authoritatively investigated in 1905 by Messrs. Colson and Ziffer. It has nevertheless appeared to me necessary to give at the beginning of this report, a short summary of their report, laying some stress on the modifications and additions which have since been made in certain countries.

I. — GERMANY.

The legislations of the different States have, at various times, occupied themselves with the subject of light railways. But it is in Prussia alone that we find a general system of subsidies established by the act of 1892.

The *Kleinbahnen* (minor railways) are never incorporated in the State Railway system. Concessions are granted either to companies, or to districts, or to communes.

As a rule, the contribution of the State is equal to that of the provinces plus that of the districts, less the cost of land. It may amount to twice as much in the case of poor provinces, and as a rule takes the form of subscribing for bonds or preference shares.

*

Construction by the districts and provinces tends more and more to become the rule, the actual operation being left to special companies of great importance which have made a speciality of this work. One of the most important is the firm Lenz, of Berlin.

II. — AUSTRIA AND HUNGARY.

AUSTRIA.

In the Austrian Monarchy, the legislation about light railways shows much variety. There is a fundamental act of 1894; but a special act may intervene in each particular case. Assistance by the kingdoms or countries represented in the Reichsrath, is generally given under conditions similar to those adopted by the State.

In certain cases, the governments of the countries take direct charge of the concession, of the construction and even of the operation.

The financial assistance given may assume the following different forms :

1° The line is built by the country in consequence of a concession for construction and operation granted to the national delegation, or in consequence of a concession granted to the parties interested, or to a private company;

2° A guarantee is given for the payment of the interest and the amortization of the preference shares;

3° Loans on mortgage;

4° Subscription of fully-paid shares;

5° Subsidies paid outright (money not repayable);

6° The holding of enquiries and making of projects.

When the States gives a guarantee, it as a rule constructs and operates the line. When a country gives a guarantee of net profit, as a rule it constructs, and the State operates the line. Lower Austria also operates the lines which it has guaranteed.

HUNGARY.

In Hungary, the light railways can receive subventions from the State, the comitats, the communes and other interested parties. Concessions are granted to companies which undertake the financial organization and must supply at least 65 per cent of the capital, in the form of preference shares.

The State subvention consists, as a rule, in subscribing 10 per cent of the capital as ordinary shares, without conditions, and a further subscription of 10 per cent as a maximum in consideration of the free carriage of mails. The comitats, communes and other interested parties, take ordinary shares up to 15 per cent, as a maximum, of the capital. As a rule, the companies leave the operation to the State Railway.

III. — ARGENTINE REPUBLIC.

Indirect financial assistance can be given to light railways in the form of free grants of State lands.

IV. — BELGIUM.

The machinery for the organization of light railways in Belgium was created by the acts of 1884 and 1885. This is the *Société nationale des chemins de fer vicinaux* (National Light Railway Company), which is really a centralized public service.

Its distinguished general manager, Mr. de Burlet, is the creator of the light railways in Belgium.

Nobody can obtain a concession for a light railway unless that concession has been refused by the *Société nationale*.

The concession is granted by royal decree. The *Société* keeps separate accounts for each line. The shares are subscribed by the public (in actual practice, only in small part), by the State, as a rule, one half, and the rest by the provinces and the communes.

The *Société nationale* generally operates by leasing.

V. — GREAT BRITAIN AND IRELAND.

ENGLAND AND SCOTLAND.

The light railways are constructed under the act of 1896. They are under the jurisdiction of the Board of Trade. A special commission deals with them.

Financial assistance is regulated as follows :

County, borough and district councils can advance sums within the limits which, in the opinion of the Board of Trade, are suitable considering the interests concerned. These sums are in the form of a loan or of a subscription to part of the share capital.

The Treasury can also make advances at a rate of interest which is at least 3·20 per cent. Such advances cannot exceed one quarter of the total capital, nor can they exceed the total subvention given by the councils. At least half of the share capital must be subscribed by the public. The Treasury can, moreover, make special advances, without interest, if the authorities consider that a line presents special advantages, from an industrial and agricultural point of view. The total amount of the subsidies must not exceed 25 millions of francs (£1,000,000), 6 millions (£240,000) of which may be in the form of special advances.

IRELAND.

An act of 1880 had provided a State guarantee together with county guarantees for some of the lines. In 1889, the whole matter was regulated by the Light Railway Act. Capital can be contributed not only when the counties give a subvention, but also when an existing company undertakes to construct and operate the line. A fund of 15 million francs (£600,000) was placed at disposal for this purpose, and was increased by 12 $^1/_2$ millions (£500,000) in 1896, by an act which limited the assistance of the State to half the cost of construction, except in certain poor districts where the only condition is a reasonable contribution by the localities.

Mr. Colson recorded in 1905 that these different measures had enabled about 1,000 kilometres (620 miles) of light railways to be constructed. On examining the documents issued by the present parliamentary enquiry, we find that up till 1909 the situation was not altered.

VI. — BULGARIA.

In this country, there is no law on the subject of light railways. Moreover, the standard-railway system is not yet completed.

VII. — CHILI.

No financial aid is given.

VIII. — DENMARK.

The construction of light railways is regulated by the act of 1894 according to which the State contributes half the cost of construction.

The provinces take up the shares or bonds of the companies. The concessionaries build and operate the lines themselves.

IX. — EGYPT.

The government grants permission for the utilization of the roads and for the gratuitous occupation of State lands.

It guarantees a net return of 900 francs per kilometre (£58 per mile) applying a coefficient of working of 60 per cent to the gross receipts. This guarantee is of very little value, for it does not apply unless receipts are below 2,250 francs (£145 per mile).

X. — SPAIN.

The light railways in Spain are regulated by the act of 30 July 1904 and by the order of the public administration of 2 November 1905.

As this legislation could not be considered at the last session of the Congress, we give particulars, in some detail.

The act consists of three chapters :

The first deals with the general conditions of existence of the light railways, concessions for which can only be granted to Spanish companies. It regulates the relations between the concessionaries and the different ministerial departments.

The second chapter deals with railways for which concessions are granted without State subventions. These can occupy certain parts of the State lands, utilize its works as well as those of the provinces and the municipalities, and be free from the taxes levied on the carriage of passengers and goods. The Minister of Public Works grants these concessions, and submits the matter to the chambers if State land is to be occupied or there is to be expropriation.

The third chapter deals with railways for which concessions with guarantee of interest by the State, are granted.

A commission under the Minister of Public Works is entrusted with the task of drawing up projects for such lines, which must not, altogether, exceed 5,000 kilometres (3,100 miles) in length, and are in groups, each of which must in principle not have less than 200 kilometres (124 miles).

These lines, in the first place, benefit by the same advantages as the non-subventioned lines.

In addition, the State guarantees the capital required for construction, rolling stock not included, a minimum rate of interest of 4 per cent for twenty years. The capital guarantee cannot exceed 50,000 pesetas per kilometre (£3,219 per mile).

The annual working expenses must not exceed 3,000 pesetas (£193 per mile). The control of the expenditure and the drawing up of the annual accounts are carried out according to special forms. When the net profit exceeds 8 per cent, the State receives half the surplus for the repayment of its advances.

If ten years after the operation of a line has begun, the State still has to make advances, the Minister can appoint a delegate to act as joint manager of the concessionary company.

The act leaves to private initiative the study of the technical conditions of construction and of the operation of the groups. The government then puts the concession for each of them up to auction. Conditions are made as to the capital to be guaranteed, the period during which the concession is to run, and the working coefficient.

When provincial or municipal councils are to undertake, either separately or jointly, the construction of the whole or of part of the system they are interested in, the government gives them the preference over any other concessionary, provided that they undertake the whole or part of the interest guarantee.

The concessionaries have to pay to the author of the approved project the cost of the initial expenses, which must not exceed 500 pesetas per kilometre (£32 per mile)

The act provides for repurchase at the expiration of the interest guarantee; the annuity to be paid till the termination of the concession is calculated from the average profit of the last five years.

If this annuity corresponds to a rate of interest, on the capital invested, of more than 8 per cent, the earlier instalments are reduced by half the surplus until the advances made by the State have been repaid.

XI. — UNITED STATES OF AMERICA.

The term " light railways " is very seldom used in the United States.

The minor lines are, as a rule, constructed with the assistance of the main lines to which they act as feeders.

The States assist. Sometimes, the countries and districts as well as the large land owners and business interests assist by money subventions or grants of land.

Some of the States have legislation on the subject, others not.

XII. — FRANCE.

The light railways and tramways in France are regulated by the act of 1880; the main object of this act was to substitute subventions in the form of annuities for the subventions in the form of capital, which were granted under the act of 1865.

The railway systems are organized by the departmental authorities. The department generally deals with a company, either for the concession of the lines or for their leasing. It is the department alone which makes the contract with the concessionary; it is the department alone which enters into negociations with the State and the communes, in order to obtain their assistance before the declaration of public utility is issued, after approval by the Council of State, on the proposals of the ministers of the Public Works, of the Interior and of the Treasury.

The State subvention cannot increase the dividends on the construction capital to more than 5 per cent. It cannot exceed that of the parties interested, namely the department, the commune, and the public. It cannot exceed two maxima, calculated by kilometre and in proportion to the gross receipts. The department can itself undertake the operation; but this as yet has only been done provisionally.

One department operates through the intermediacy of the State Railway.

In June 1908, Mr. Barthou, minister of Public Works, presented a bill to amend the act of 1880.

The preamble of the bill contains very interesting information on the light railways and tramways of France.

The principal provisions of this project are as follows :

The distinction, which is frequently very artificial, between " railways of local interest " and " tramways " is abolished. The procedure in connection with the

concession and the enquiries is simplified and made more practical. The declaration of public utility is made by decree and no longer requires an act.

The subvention of the State, as before, cannot exceed the contributions made by the department and the communes, including those made by the public. No subvention is given by the State, if the traffic is insufficient. As a matter of fact, it may be stated that the departments do not do more; any railway which cannot even pay its working expenses appears useless, except in particular cases in which the department undertakes the whole business alone. The bill regulates the question of the maximum subvention given by the department, and specifies the different ways in which such subvention can be made. The construction capital is calculated either on the basis of the real and properly justified expenditure, or according to a system of a series of rates.

The working expenses are calculated, either on the basis of their actual amount, or according to a formula which takes into consideration the receipts, the number of the trains, and, the case arising, the importance of the traffic. The preamble lays special stress on the importance of taking into consideration the number of trains. In order to promote the development of the traffic, which necessitates an increase in the number of trains, it is necessary to allot the concessionary a sum which covers, not the whole cost of those trains, but that part of that cost which is not covered by the fraction of the receipts, which according to the formula goes towards working expenses. The concessionary cannot be an individual person, but must be a corporate body or company.

XIII. — DUTCH INDIES.

Regulations issued in 1893 enabled the light railway system, which only included 281 kilometres (175 miles) in 1893, to grow to 1,900 kilometres (1,180 miles) in 1900.

These regulations do not provide for any subvention, but regulate the use of the public roads and grant facilities of construction subject to the condition of limitation of speed; this as a rule must not exceed 25 kilometres (15·5 miles) per hour.

The operation is by concessionary companies.

Four of the chief ones, although quite distinct, have a joint management, and every employee is bound to accept from the management an appointment in any one of the companies concerned. This regulation does not apply to the lower-grade employees.

XIV. — ITALY.

The light railways are regulated by the act of 1896.

The scales of rates fix in each case the maximum tariffs and the measures necessary for combining safety of working with reasonable economy.

The act specifies that no guarantee of kilometric receipts can ever be given, and that the operation is to be by private parties.

The State can participate in the cost of construction by making kilometric subventions. The 1873 act specified that the annual subvention per kilometre must not exceed 1,000 francs (£64 per mile). This maximum was raised by other acts to 6,000 and to 8,000 francs (to £386 and to £515 per mile).

The provinces, communes and other bodies can give subsidies, preferably in the form of a subvention per kilometre, under conditions specified in an act of 1894; but the Council of State has power to modify these conditions.

An act of 1907 has given powers to increase up to 5 million lire (£200,000) the total subventions given by the State to railways for which concessions have been granted to private parties. It has also given powers to grant, for a term of not more than thirty years, subventions up to 2,000 lire per kilometre (£129 per mile) for the construction of tramways connecting important places with the railway stations.

XV. — NORWAY.

The State grants assistance to light railways, but there is no general law regulating the matter. Each subvention is the subject of a special act.

The contribution of the State generally represents half the cost of construction. The construction is carried out by the concessionary. The operation is by a council of administration appointed by the parties interested. The State reserves the right of appointing one of its members.

XVI. — HOLLAND.

Financial assistance is given by the State, the provinces and the municipalities.

Every subvention is the subject of a special act. Some of the provinces have issued regulations as to their contributions.

The financial assistance takes the form of an advance without interest, of a loan bearing interest, of participation in the capital.

The State, the provinces and the municipalities never undertake the operation, which is either by the concessionary or by the main-line railways.

XVII. — PORTUGAL.

An act of 14 July 1899 regulates, in a general way, the assistance given by the State and the corporations to the lines supplementing and feeding the State Railway system.

This act establishes a special fund for carrying out new work on the State system, and also for studying and constructing lines supplementing and feeding that system.

The facilities given are as follows :

1° Admission of materials and rolling stock duty-free;

2° Free carriage on the State lines of the materials used in building the lines ;

3° Annual subvention during thirty years equal to 50 per cent of the net receipts brought to the State system by the feeder lines;

4° Authorization to the municipal councils to pay the cost of expropriation;

5° Authorization to the juntas to levy as subsidies for the undertaking additional taxes, to an extent not exceeding 3 per cent of the latter;

6° Authorization of charging rates 40 per cent higher than those of the State Railway;

7° Exemption for thirty years from stamp and transport duties;

8° Exemption during thirty years from the tax on shares.

In March 1904, a bill was submitted creating a special fund for the railways in the central zone. — This bill increases the facilities granted by the act of 1899 and provides for guarantees of interest.

It has been made the subject of favourable report at the Cortes, but has not yet been passed.

In 1906, regulations were issued concerning railways on high roads.

Before and after 1899, concessions were granted for a certain number of light railways by special acts, with subventions of various kinds, including guarantees of net profit and of interest.

XIX. — RUMANIA.

The light railways are regulated by the act of 1898. There is no financial subvention. The lines are entitled to the gratuitous possession of State and Crown lands, and have indirect advantages and great facilities for operation.

XX. — RUSSIA.

The act of 10 June 1905, passed after the Russo-Japanese war, makes the first reference to light railways.

This act, which applies to private capital for the reorganization and extension of the national railway system, and regulates the different modes of the public treasury, contains a paragraph worded as follows :

In the cases of lines which are only of local importance, or which will be constructed at the personal cost of the promotors, capital will be advanced by the Treasury under given conditions.

XXI. — SERVIA.

Acts of 1898, 1899 and 1902 provide for a system of lines which can either be constructed by the State, or for which concessions can be granted. No financial

subventions are provided, but there are indirect advantages of various kinds, including the right of working mines within a certain distance.

XXII. — SWEDEN.

The public authorities, the general councils, and the municipalities can give financial assistance and actually do so, but there are no general legal provisions in existence.

The assistance consists in the subscription to ordinary and preference shares by the different bodies. The State and the provinces guarantee bonds.

Construction and operation is as a rule carried out by the concessionaries.

The State operates one line.

Ten lines are operated by neighbouring main-line railways.

XXIII. — SWITZERLAND.

The light railways are regulated by the federal act of 1899.

A light railway (*Sekundärbahn, chemin de fer secondaire*) is defined as a railway not utilized for through passenger and good services.

The Federal Council grants concessions for all railways and determines their character.

Nothing prevents a line from changing its character during the course of its working.

The Federal Council gives no subventions for the construction of secondary railways. The cantons can on the contrary give subventions underce rtain conditions and within the limits fixed by their own laws. The operation is as a rule by companies and the subvention is given in the form of a subscription, by the canton, to part of the company's capital.

The Rhetian Railway has received a subvention in a special way, not only from the canton (the Grisons), but also from the Federation.

XXIV. — TURKEY.

All the railways of this country may be considered light railways. As a rule, the State grants free land and a guarantee of gross receipts; this enables the concessionaries to raise the capital and to issue bonds which are secured, by the government, on certain revenues.

ANALYSIS OF THE ANSWERS AND OF THE DOCUMENTS.

Having given an account of the legislation in the principal countries, we will now proceed to consider the question set by the Congress, which we have amplified as shown by the list of questions which is given in an appendix. We have received very few complete answers. Below we give a summary of those which we have received and of the documents which we have been able to procure.

I. — GERMANY.

Although there are many light railways (*Kleinbahnen*) in Germany, we were unable to obtain any information from the people operating them.

The State Railways informed us that they did not operate any light railways; the companies operating them do not belong to the Congress. Our personal enquiries led to no result; we were always received courteously, but could obtain no information. It is evident that those concerned do not wish the results of the working known.

We are therefore only able to give a summary of the documents published by the *Zeitschrift für Kleinbahnen* and analysed by the *Revue des chemins de fer* :

It should first of all be noted that there are in Germany 5,690 kilometres (3,535 miles) of narrow-gauge lines, which are classed, by the Imperial Railway Office, as main lines; of them 2,870 (1,783 miles) are State lines, and 2,820 kilometres (1,752 miles) company's lines.

The average cost of construction of those lines, per kilometre, was 82,648 marks (£6,647.18*s*. per mile) in the case of the State lines; and 69,355 (£5,580.14*s*. per mile) in that of company's lines.

The receipts and expenses in 1906, per kilometre, were 6,126 and 5,239 marks (£492.18*s*. and £421.11*s*. per mile) in the case of State lines, and 7,627 and 5,298 marks (£613.14*s*. and £426.6*s*. per mile) in that of company's lines, respectively.

The net profit from working earned on the capital outlay was from 0·63 to 1·63 per cent in the case of State lines, with an average of 1 per cent. In the case of the companie's lines the average was 3·34, the mean of both together being 2·33 per cent.

The *Kleinbahnen* are of two kinds, tramways proper and light railways; and it is only the latter that we are considering.

In December 1907, there were in Prussia 247 undertakings of this kind, having a total length of 8,351 kilometres (5,189 miles); in the other States there were 16 such undertakings, with a total length of 373 kilometres (232 miles).

If we remember that at the time when the *Kleinbahnen* act was passed (1892),

such railways had in Prussia a total length of 159 kilometres (99 miles) only, we see how much development there has been under this act.

In Prussia :

50 per cent of these lines have a gauge of 1·435 metres (4 ft. 8 1/2 in.);
19 — — — — — of 1·00 metre (3 ft. 3 3/8 in.);
15·4 — — — — — of 0·75 — (2 ft. 5 1/2 in.);
4·1 — — — — — of 0·60 — (1 ft. 11 5/8 in.).

11 per cent of these lines have various gauges.

In Prussia, 161 lines were built by companies. The communes only built 79, with a total length of 3,075 kilometres (1,910 miles). As Mr. Colson has explained, the working is not in the hands of the owners. It has the character of an industrial enterprise.

The staff employed in Prussia included :

5,074 higher-grade employees;
6,464 lower-grade employees.

In other States, it included :

213 higher-grade employees;
134 lower-grade employees.

The total receipts increased in 1906, as compared with the previous years, by 4·21 million marks (£210,500) or 13·1 per cent in Prussia, and by 4·35 million marks (£217,500), or also 13·1 per cent, in the whole of Germany.

The working coefficient for the whole of Germany has increased from 67·1 to 67·3 per cent.

Calculated in marks per kilometre of line operated, the working results in 1906 were as follows :

	Receipts, per kilometre (per mile). Marks. (£ s.)	*Expenses, per kilometre (per mile).* Marks. (£ s.)	*Net profit, per kilometre (per mile).* Marks. (£ s.)
Prussia	4,729 (380.10)	2,923 (235. 4)	1,543 (124. 3).
Other states.	7,925 (637.14)	5,472 (440. 6)	2,453 (197. 8).
Mean for Germany.	4,798 (386. 1)	3,227 (259.13)	1,562 (125.13).

The capital expended on light railways amounted in 1906 to :

Prussia. . . . . 483,598,951 marks (£24,179,947.11*s.*).
Other states . . . . . 11,260,002 — (£563,000. 2*s.*).
The whole of Germany. 494,858,953 marks (£24,742,947.13*s.*).

In Prussia, the mean cost per kilometre was : 78,138 marks (£6,287.8*s.* per mile) for the standard-gauge lines and 47,892 marks (£3,853.13*s.* per mile) for the narrow-gauge lines.

The capital is made up as follows :

In Prussia the capital was contributed :

By the State (subvention fund) . . .	72,509,761 marks	(£3,625,488. 1*s.*)
— provinces	60,558,562 —	(£3,027,928. 2*s.*)
— districts	105,597,624 —	(£5,279,881. 4*s.*)
— promoters	54,189,668 —	(£2,709,483. 8*s.*)
Miscellaneous	190,743,336 —	(£9,537,166.16*s.*)

In the other German states, the capital for the light railways was contributed :

By the States	3,713,586 marks	(£185,679. 6*s.*)
— districts	296,000 —	(£14,800.)
— promoters.	1,023,824 —	(£51,191. 4*s.*)
Miscellaneous.	6,226,592 —	(£311,329.12*s.*)

We can give figures as to the results obtained by 216 undertakings in Prussia :

16 earned no dividend;
36 earned one of up to 1 per cent;
55 earned from 3 to 4 per cent;
15 earned from 4 to 10 per cent;
4 earned more than 10 per cent.

3,018,425 marks (£150,921.5*s.*) were distributed as dividends, or 550,000 marks (£27,500) more than the previous year.

Ten railways distributed a dividend of more than 5 per cent; 33, a dividend varying between 3 to 5 per cent; and finally, 29, a dividend of less than 3 per cent.

II. — AUSTRIA AND HUNGARY.

AUSTRIA.

Administration of the State Railway.

The Minister of Railways states that at the end of 1907, there were 104 light-railway concessionary companies who had their lines operated by the State Railway. The total length of these lines is 4,220 kilometres (2,622 miles), 385 kilometres (239 miles) being of narrow-gauge.

The different kinds of concessions granted provided for the assistance of the State, of the countries, of the districts or the parties interested, in order to guarantee interest or to help to raise the capital. The two methods : participation in the capital and guarantee of interest are in practice, combined in such a way that some of the parties named above assist in contributing the capital while others guarantee the interest on the preference shares. The line is built either by the concessionary or by the Administration of the State Railway.

The stores are charged to a special fund, and remain the property of the local

company. The rolling stock, also the property of the local company, is built to designs approved by the Minister. In case of temporary shortage, the State supplies stock on hire, against payment. It has an absolute right of disposal and of user of the stock of the local company, without any payment.

The cost of extending stations to accommodate local railways is paid by the latter. The local company has the right of using, for its lines, all the appliances at the joint station; but the land acquired and installations made become wholly the property of the operating administration. Nothing is paid for the right of user, as long as the annual receipts of the company are not sufficient to pay the interest fixed for the preference shares. When this figure is attained, the local company contributes to the payment of the interest of the capital outlay on the station in proportion to its share of the traffic.

All the subsequent expenditure is shared in the same way,

The tariffs fixed by the scale of rates can be reduced by the operating administration, to a minimum fixed by the convention. The financial arrangements concerning the working are made in various ways :

1° The operation is carried out subject to the payment of specialized expenses. The general expenses and the non-specialized expenses are paid in accordance with a formula mutually agreed on. As long as the fixed interest on the preference shares is not paid, all the reductions legally possible are granted to the local company ;

2° One part of the gross receipts is handed over by the local company;

3° The operating administration receives either a fixed sum per kilometre or a fixed lump sum.

The Minister considers that the local companies having their lines operated by the State Railways have the following advantages :

a) Right of user of the joint stations, subject to their eventual extension;

b) Operation by a staff which is properly trained;

c) In case of temporary increase of traffic, the local company is supplied by the operating administration with the necessary rolling stock and extra staff, without having to contribute to the cost entailed by the provision of such a reserve.

The Administration of the State Railway, by specializing the staff managing the light railways, has reduced the coefficient of working to 50 per cent.

Austrian North-Western and South-Northern Company.

The company operates several light railways for their owners on one of the following bases :

1° Paying the operating company a percentage of the gross receipts, starting from a certain minimum ;

2° Payment of the cost of working.

In consequence of the continual growth in the working expenses, the first system

has not given satisfaction. In the future, no agreements will be made with light railways except on the basis of payment of the cost of working.

Bukovinia Light Railway.

The Bukovinia Light Railway Company has a system of 217 kilometres (135 miles), which was built with the assistance of the Austrian State Railway and the Lemberg-Czernowitz Railway Company. One part of the system was operated by the Lemberg-Czernowitz Company until 1907, and then by the State, when it took over that railway. The other part was always operated by the State. The operation by the State is carried out under the conditions mentioned in the answer of the Minister of Railways, analysed above.

The company asserts that operation by the State tends to cost more than separate operation, but that it is necessitated because the system is in two separate portions. The company states : " If we operated the line ourselves, we would be able to reduce the cost of maintenance of the line, the cost of the station working and of the trains. On the other hand, the cost of maintenance of the rolling stock would increase, as the workshops necessary would not be fully occupied. The cost of management and of offices would also be greater ".

Under these conditions, the company considers the method of working adopted, as advantageous both to itself and to the State; it is also a great advantage to the public owing to the facilities for the exchange both of passengers and of goods.

The company states that the operation contracts enable them to exercise sufficient regulating influence on the fixing of the traffic, on station extensions and station working, and on the increase of rolling stock.

The working results, in kronen per kilometre (per mile), were :

YEAR	Receipts.	Expenses.	Net profit.
1900	10,453·81 (£693.17*s.* 1·56*d.*)	5,486·72 (£367.6*s.* 5·33*d.*)	4,967·09 (£332.10*s.* 8·23*d.*)
1901	10,145·77 (£679.4*s.* 8·16*d.*)	5,358·04 (£358.14*s.* 1·78*d.*)	4,787·73 (£320.10*s.* 6·38*d.*)
1902	10,281·12 (£688.5*s.* 10·88*d.*)	4,537·27 (£303.15*s.* 2·14*d.*)	5,743·85 (£384.10*s.* 8·74*d.*)
1903	11,731·19 (£785.7*s.* 5·74*d.*)	4,833·64 (£323.12*s.* 0·03*d.*)	6,897·55 (£461.15*s.* 5·71*d.*)
1904	11,747·48 (£786.9*s.* 3·48*d.*)	5,460·72 (£365.11*s* 7·58*d.*)	6,286·76 (£420.17*s.* 7·90*d.*)
1905	11,648·44 (£779.16*s.* 8·16*d.*)	4,625·25 (£309.12*s.* 11·75*d.*)	7,023·19 (£470.3*s.* 8·41*d.*)
1906	13,024·86 (£871.9*s.* 7·65*d.*)	5,610·01 (£375.11*s.* 6·28*d.*)	7,414·85 (£496.8*s.* 1·37*d.*)
1907	13,754·80 (£920.16*s.* 11·89*d.*)	7,540·18 (£504.15*s.* 11·10*d.*)	6,214·62 (£416.1*s.* 0·79*d.*)

HUNGARY.

Administration of the Hungarian State Railway.

The Hungarian State Railway in 1907 operated altogether 16,240 kilometres (10,091 miles) of railway lines, 8,111 kilometres (5,040 miles) of which were light railways.

The latter can be classified under four heads :

1° Five lines of 298 kilometres (185 miles) are operated on account of the State Railway. The State Railway pays the companies either an annual fixed rental, or annually the amount of a supplement levied on the transport rates. This is quite a special system of operation limited to exceptional cases;

2° 69 kilometres (43 miles) are operated on account of the owners who pay the real working expenses plus 10 per cent;

3° Eight lines, 330 kilometres (205 miles) long, belonging to the State;

4° One hundred and five lines, length 7,744 kilometres (4,812 miles), belonging to concessionary companies and operated on the " standard contract " basis. It is these lines, forming the greater part of the system, which present the most interesting features. The " standard contracts " are made for a period of ninety years. At first the standard contract provided that the working expenses should be paid on the basis of kilometre rates fixed in advance for every actual conveyance of passengers and of goods. After the zone tariff was established, and extended to the light railways, it became necessary to modify the standard contract.

The amount to be paid to the State was fixed for passengers, luggage and goods at 50 per cent of the receipts derived therefrom.

Several contracts have been modified on the basis of a fraction of the receipts :

In kronen per kilometre (per mile) :

the mean receipts were	5,845 kronen	(£391. 6*s.*),
the mean expenses were	2,932 —	(£196. 6*s.*),
and the mean profit	2,551 —	(£170.16*s.*).

In 1907 :

the total expenses were	29,273,024 kronen	(£1,217,757.16*s.*),
the total receipts were.	19,775,662 —	(£822,667.11*s.*),
The difference. . .	9,497,362 kronen	(£395,090. 5*s.*),

chargeable to the State, represents an annual working subvention of 1,226 kronen per kilometre (£82.1*s.* per mile).

The concessions for the lines were granted under the following conditions :

The amount of capital is fixed in the concession. The stock which the companies have the right to issue consists as a rule of ordinary shares, to the extent of 35 per cent of the capital, and of preference shares, to the extent of 65 per cent, of

the capital. The State, as subvention, subscribes up to 20 per cent of the capital in the form of ordinary shares, the remainder being subscribed by the parties interested, namely the comitats, the communes and the public, the latter generally only to a slight extent. The ordinary shares receive no dividend until 5 per cent has been paid on the preference shares.

Out of a total capital of 639,871,600 kronen (£26,618,658), there are :

443,449,300 kronen	(£18,447,490)	in preference shares;				
196,442,300	—	(£8,172,000)	in ordinary shares;	of the latter		
79,184,120	—	(£3,294,060)	were subscribed	by the State;		
46,696,620	—	(£1,942,580)	—	—	—	comitats;
36,798,990	—	(£1,530,838)	—	—	—	by the towns and communes.

The lines were built by the concessionaries on the basis of projects approved by the government.

The additional tracks and track appliances at the joint stations are constructed by the engineers of the State Railway.

The estimates serving as basis for determining the capital, provide a certain sum for the locomotive power required during the first few years of working. This sum is paid to the State which supplies the locomotive power and the rolling stock necessary for the service, in consideration of an annual payment fixed at 10 per cent of the receipts which the State receives every year for operating the line. Interest at the rate of 5 per cent on the lump sum paid for the company, is deducted from this payment.

In the case of narrow-gauge lines, the rolling stock is supplied out of the original capital. There are however only five such lines, having a gauge of 0·76 metre (2 ft. 6 in.).

The light railways operated by the State Railway form by far the greater part of the secondary railway system.

While those which we have just considered represent a capital of 639,000,000 kronen (£26,582,400), the capital of the independent lines is less than 10 per cent of this amount.

As we have seen, the operation of the light railways means a considerable loss to the State Railway. This loss is a subvention which the State readily grants these lines, many of which would not have been built and could not exist without such assistance. These lines, however, act as feeders to the State Railway which recovers part of its loss by the increase in receipts.

III. — BELGIUM.

All the details in connection with the working of the *Société nationale des chemins de fer vicinaux* have been explained at the last session of the Congress, and a summary of them has been given in the first part of this report. We cannot, moreover,

*

do better than to refer our readers to the work published by Mr. de Burlet, in 1907, which is an absolutely complete treatise on the subject.

The *Société* does not itself undertake the operation, except when a line is to be opened by sections, or when nobody has taken it up and when a favourable time is awaited for leasing it. This is a very exceptional case for, in 1907, out of 133 lines with a total length of 3,095 kilometres (1,923 miles), there were only 5, length 168 kilometres (104 miles), to which this applied.

Leases are granted on the basis of a general contract, supplemented by special clauses forming a special contract for each line.

IV. — GREAT BRITAIN.

The English railways have not supplied us with any documents which throw any light on the subject which we are considering.

The only information we were able to collect were the reports published in the *Zeitung des Vereins* and the *Revue des chemins de fer.*

At the end of 1906, the total number of concessions ("orders") that had been applied for was 520, for a total length of 7,150 kilometres (4,443 miles), and a total outlay of 877,000,000 francs (£35,080,000), in accordance with the act of 1896, which has been very difficult of application.

Light railways are of three classes :

Class A includes the lines on a special roadbed, as a rule with steam traction, and of an agricultural character;

Class B includes lines on roads and highways, as a rule with electric traction, and intended to carry passengers;

Class N includes the lines belonging neither to class A nor to class B.

Only in the case of class A are subventions given. 189 applications, for a total length of 3,762 kilometres (2,338 miles), belong to this class. 124 schem were approved by the Commission; 116 came before the Board of Trade.

255 applications, for a total length of 3,086 kilometres (1,918 miles), belong to class B. 132 were approved by the Commission and came before the Board of Trade.

Out of 27 applications, belonging to class N, 7 were approved and came before the Board of Trade.

If we examine the progress of the application of this act, we find that of late the number of applications has become reduced and that up to the end of 1906, the Board of Trade had granted orders for the construction of 2,783 kilometres (1,729 miles); but of all these lines only 885 kilometres (550 miles) have actually been opened to traffic, and this shows the comparative failure of the act.

This want of success appears to be due to costliness of construction, resulting from the cost of work, the habits of the engineers and the requirements of the authorities.

The Board thinks that it is possible to improve the state of affairs, and to construct many lines which are wanted, if certain provisions of the 1896 act are modified, and if the lines receive subsidies from the State, the counties and the parishes interested.

V. — DENMARK.

The Danish State Railway states that it operates two light railways : one of 38 kilometres (24 miles) and one of 16 kilometres (10 miles).

In the one case, the State contributed 10,700 kroner per kilometre (£964 per mile), in the other half the capital.

VI. — SPAIN.

Spain has not supplied us with any information. The railway act is as yet too recent to have produced any result.

VII. — FRANCE.

We extract the state of affairs, as concerning light railways on the 31 December 1906, from the preamble of the bill presented in 1908.

At that time there were in existence in France 12,196 kilometres (7,578 miles) of light railways, if we include among light railways the overground tramways carrying both passengers and goods.

CLASS.	Length in kilometres (in miles).	Cost per kilometre (per mile).
A : Railways, act of 1865	1,029 (639)	129,818 francs. (£8,356.14*s.*)
B : Railways, act of 1880	6,263 (3,892)	69,983 francs. (£4,505)
C : Tramways for passengers and goods of all kinds . . .	4,906 (3,048)	53,809 francs. (£3,463.17*s.*)

The financial results obtained in these three classes were :

CLASS.	Cost of construction.	Gross receipts.	Working expenses.	Net receipts.	Dividends.
A	133,582,253 (£5,343,290.2*s.*)	8,919,929 (£356,797.3*s.*)	6,116,990 (£244,679.12*s.*)	2,802,939 (£112,117.11*s.*)	2·10
B	438,302,692 (£17,532,107.14*s.*)	22,927,341 (£917,093.13*s.*)	17,832,979 (£713,319.3*s.*)	5,094,362 (£203,774.10*s.*)	1·16
C	263,986,118 (£10,559,444.14*s.*)	18,337,352 (£733,494.2*s.*)	15,482,152 (£619,286.2*s.*)	2,855,200 (£114,208)	1·08

We analyse below the different answers received, which are unfortunately but few in number.

Administration of the State Railway.

This administration operates the standard-gauge light railway between Ligré-Rivière and Richelieu in the Indre-et-Loire department, and the 1-metre (3 ft. 3 3/8 in.) gauge mechanical-traction system of tramways of the Vendée department.

The Ligré-Rivière to Richelieu line is operated on a system such that the operator runs no risk of loss nor chance of gain.

The Vendée system has a length of 210 kilometres (130 miles).

The system of working is as follows; the operation is at the risk of State Railway; the expenses per kilometre are fixed on a scale of $750 \frac{2 \times R}{3}$, with a minimum of 2,200 francs (£142 per mile) and a premium of one third of any saving effected; any resulting new profit is in the first place applied to pay off the deficit account, and the surplus goes to the department. When the net profit the department receives exceeds 4 per cent, the surplus is equally divided between the State Railway and the department. The operator forms a reserve fund, not exceeding 3,000 francs per kilometre (£193 per mile), which remains his property.

Orleans Railway Company.

The Orleans Railway Company states that it holds concessions for 318 kilometres (198 miles) of 1-metre (3 ft. 3 3/8 in.) gauge lines which it leases to three companies who themselves built the lines on plans agreed upon, and for the account of the Orleans Company. The latter supplied the rolling stock, the fittings and the tools, of patterns jointly agreed upon.

The results of this leasing appear advantageous; on the one hand, it was possible to arrive at an economic method of operation; on the other, the public benefits by the agreement between the great and the small line, as all transhipment charges are eliminated.

The leasing companies keep accounts of receipts and expenses. The expenses account is increased by 5 per cent to cover the cost of the central administration, and by 150 francs per kilometre (£9.13 *s.* per mile) per year to cover the renewal of the line and the rolling stock, and to meet unexpected expenses.

Any losses are charged to the Orleans Company if the receipts are less than 2,600 francs (£167 per mile); the expenses must not exceed this figure.

If the expenses are less than 2,600 francs (£ 167 per mile) the profit if any, goes to the lessee. Beyond that, it is divided between the lessees and the Orleans Company.

Côtes du Nord Railway Company.

This administration operates 222 kilometres (138 miles) constructed by the department to which it supplied the rolling stock. The company supplied one quarter of the cost of construction to the department. This capital pays interest and is repayable by annuities. The system has, on the whole, been satisfactory, but the result depends very much on the ability of the engineer to whom the department entrusts the construction, as his authority is absolute. The company desires that the lessee should have a voice in the drawing up of projects, with arbitration in in case of disagreement, and that matters should be arranged by a commission appointed by both parties.

Landes Railway Company.

This company operates a system of 215 kilometres (134 miles), which it built itself. The capital is guaranteed by the Midi Railway Company which supplies the rolling stock, against hire, and exercises a supervision in order to improve the returns. The lines in question act as feeders to the Midi Company, so that not only have the returns of the lines themselves to be considered, but also the traffic they bring the Midi.

Tarn Department Railway Company.

This company operates 89 kilometres (55 miles) which it has constructed; the interest and amortization are paid by the department. It has no subvention and operates on the formula $1{,}000 + {}^{3}/_{4}$ R, with $^{2}/_{3}$ of savings effected. No opinion is expressed as to the results obtained.

VIII. — ITALY.

We have received no answer of any interest. Certainly the 1907 act has not yet been able to produce any effect.

IX. — DUTCH INDIES.

The government of the Dutch Indies states that the questions of leasing and joint working have not arisen, for the State and the different railway and tramway companies only operate lines they themselves have constructed.

On 31 December 1905, there were 1,899 kilometres (1,180 miles) of light railways in existence, most of them having a gauge of 1·067 metres (3 ft. 6 in.).

The cost of construction varies between 151,000 florins (£20,220 per mile) (this

figure applies to the Batavia tramways) and 25,000 florins (£3,350 per mile), the mean being 30,000 florins (£4,020 per mile).

The working expenses are lower than in the case of the main-line railways, but the undertakings by no means all show favourable results.

X. — NORWEGIAN STATE RAILWAY.

The Norwegian State informs us that there are in Norway nine light railways, total length 342 kilometres (212 miles); 110 kilometres (68 miles) of them have a gauge of 1·45 metres (4 ft. 9 in.), and the rest have narrow gauges of various sizes.

The State generally contributes half the capital. Of this half, 50 per cent is payable outright, and the other 50 per cent is in the form of shares.

The lines are operated by concessionaries. The concessions are granted by royal order after approval by the Storthing.

The average cost of the standard-gauge lines was 43,000 kroner per kilometre (£3,875 per mile). The cost of the narrow-gauge lines varied between 27,000 and 40,000 kroner per kilometre (between £2,430 and £3,600 per mile).

In 1907, the receipts varied between 1,198 and 2,600 kroner per kilometre (between £107.19*s.* and £214 per mile), and the working coefficient between 112 and 68 per cent.

The coefficient 112 per cent corresponded to receipts of 2,113 kroner (£169.6*s.* per mile) in the case of line 21 kilometres (13 miles) long and having a gauge of 1·067 metres (3 ft. 6 in.).

The coefficient 68 per cent corresponded to receipts of 1,940 kroner (£155.8*s.* per mile) in the case of a line 26 kilometres (16 miles) long and having a gauge of 0·75 metre (2 ft. 5 $^1/_2$ in.).

XI. — HOLLAND.

Dutch Railway Company.

The Dutch Railway Company operates about 400 kilometres (248 miles) of light railway which it leases from the concessionary companies.

All these lines, which have a gauge of 1·45 metre (4 ft. 9 in.), are operated jointly with the corresponding main lines. The expenses are included in the general expenses of the system. A separate account is kept of the receipts.

Without entering into detail about the leasing contracts, the company states that the result is satisfactory to both parties concerned.

It considers that the essential clauses of the leasing contract are :

1° As regards the track and the stations : the approval of the plans and the general supervision of the future operator during the construction; a double examination of the works at the beginning of the operation and two years after;

2° As regards the rolling stock : the approval of the plans by the operator, unless he provides it himself;

3° As regards the operation : the operator must be interested in the development of the traffic.

Company operating the Dutch State Railway.

This company leases 172 kilometres (107 miles) of light railway. It states that the results are satisfactory, and that the clauses desirable vary in the case of each line and each district.

XII. — PORTUGAL.

Portuguese National Railway Company.

The Portuguese National Railway Company operates two 1-metre (3 ft. 3 3/8 in.) gauge lines, one 55 kilometres (34 miles) long and the other 80 kilometres (50 miles) long. It has a guarantee of 4·5 per cent on the cost of construction per kilometre, fixed by agreement. The working expenses are taken equal to 50 per cent of the gross receipts, with a minimum of 3,900 francs (£251 per mile) and a maximum of 6,600 francs (£425 per mile). Any surplus or net receipts are divided equally between the State and the concessionary. The actual working expenses are 2,800 francs (£180 per mile); as the minimum expenses are fixed by the concession at 3,900 francs (£251 per mile), there is a profit of 1,100 francs per kilometre (£71 per mile).

The company observes that it is to the advantage of the concessionaries to keep the receipts near the minimum fixed for the expenses, and this might be a disadvantage to the public; it states however that in Portugal, fortunately, concessionaries are not tempted to abuse their contracts.

XIII. — RUSSIA, BRITISH COLONIES, UNITED STATES OF AMERICA.

The few answers received from Russia, the British Colonies und the United States do not give us any information of interest concerning the question under consideration.

This is apparent from the information given in the first part of our report.

XIV. — SWITZERLAND.

The Swiss light railways have not supplied us with any information.

The figures for 1907 and 1908 are :

—	Length, in kilometres (in miles).		Receipts, in millions of francs.	
	1907.	1908.	1907.	1908.
Standard gauge	694 (431)	744 (462)	11·200 (£448,000)	11·500 (£460,000)
Narrow gauge	872 (542)	917 (570)	12·178 (£487,120)	12·975 (£519,000)
Rack railways	39 (24·2)	39 (24·2)	1·597 (£63,880)	1·543 (£61,720)
Tramways	365 (227)	377 (234)	11·739 (£469,560)	12·475 (£499,000)
Cable railways	18 (11·2)	18 (11·2)	1·205 (£48,200)	1·288 (£51,520)

This information is taken from the *Feuille du Commerce*. It is of course evident that rack and cable railways are in no way light railways.

The mean receipts per kilometre (per mile) were 15,460 francs (£995.4*s*.) for the standard-gauge lines, 14,120 francs (£908.19*s*.) for the narrow-gauge lines, 39,568 francs (£2,547.2*s*.) for the rack railways, 72,528 francs (£4,668.16*s*.) for the cable railways and 33,110 francs (£2,131.8*s*.) for the tramways.

CONCLUSIONS.

Under the laws existing in each country, light railways have taken and are every day taking a greater development in all the countries where there is a main-line system forming a close network. England and the United States are however exceptions. The situation is not materially different from that expounded in 1905 by Messrs. Colson and Ziffer.

It is difficult to answer question XVIII such as it has been formulated by the Congress, and to give the results of the different systems enumerated in operating light railways.

Many administrations have sent no information. More especially have we received no answer from Prussia and Germany; here we can only record that the operation is by private enterprise. In France, the authors of the answers sent to us have not given any definite answer. We have only received really clear and concise answers from Belgium, Austria and Hungary. The formula of the *Société Nationale des chemins de fer vicinaux*, which has produced such happy results in Belgium, is so

well known that it is unnecessary for us to draw attention to it. In Austria and in Hungary, we have operation by the State. In Hungary, the Minister informs us definitely that working by the State involves a loss of 10 million kronen (£416,000); and this is the subvention necessary for establishing the light railways.

Under these conditions, we will not undertake to draw up any conclusions. At most we will allow ourselves to formulate a personal appreciation.

Everything concerning concessions was expounded by Mr. Colson to the 1905 Congress, and has been repeated in the preamble and the annexes of the bill concerning light railways brought before the Chamber of Deputies of France. Mr. Colson expounded, with his great authority, how important it is to pay attention to the factor train-kilometres, so as to induce the operator to develop traffic. But once this has been said, nobody ventures to state what the result of the formulae in use is, or to lay down other complete ones.

To us, this is a consequence of the economic transformation which results, in every country, from the new social conditions.

It is necessary that the formula of operation should allow the operator to live; it is at present very difficult to find a satisfactory one, as expenses are continually growing. We are not far from thinking that the solution to be preferred is that of contract working as described by an Austrian company.

APPENDIX.

Detailed list of questions relating to question XVIII.

I. — Leasing.

1. Do you operate lines leased by you? If so, mention their length and gauge. Can your rolling stock be interchanged with other lines? State whether your railway system consists solely of leased lines.

2. Are your lines leased by concessionary companies or by collective bodies such as the State, a department, province or commune?

3. Is the sole object of your company the operation of leased lines?

4. Have you been concerned in any way with the construction of the lines and the supply of their rolling stock? Were the plans submitted to you before construction? Had you any share in the construction, as regards for instance the roadbed and the building of the stations? Did you afford financial assistance towards the construction? In what circumstances can you demand an increase in the rolling stock?

5. For what period does your contract last?

6. State as fully as possible what results have been obtained? Mention the advantages and disadvantages of the regime, both as regards the public and the two contracting parties.

7. What are in your opinion the essential clauses to be introduced into a leasing agreement to ensure good operation from the standpoint of laying down the track, arranging the stations, supplying rolling stock and what is the best way of stimulating the operator to develop the traffic.

II. — Joint operation with the corresponding main railway.

1. Have you any lines operated jointly with the corresponding main railway, understanding by the term joint operation, a genuine leasing of the light line by the main line which incorporates it in its own system.

2. What are the reasons which induced you to adopt this method? Explain how the system works from the standpoint of earnings and expenses.

III. — Operation by the concessionary himself.

1. Do you operate your lines yourself? If so, state the length of the lines open? Is your line disconnected at both ends? What is the gauge? Can you interchange your rolling stock with other lines?

2. What is the working formula of your concession? Do you get a subsidy or a guarantee from the authority granting the concession? What formula is imposed upon you in calculating the guarantee? Has the authority granting the concession to take a share in the increase of the rolling stock and in the enlargements necessitated by the growth of traffic?

3. State, in the broadest manner possible, the results of your operating and the advantages and the disadvantages of the system followed to the public, the concessionary and the authority granting the concession.

4. What in your opinion is the best formula to be employed, both as regards the concession and the operation of the line, so as to stimulate the concessionary to develop the traffic?

IV. — Additional questions.

Have you any lines that you operate yourself, but for which you have received assistance from the corresponding main line, either in that it has helped you in getting your capital, or that it helps you in operation, by lending you if required rolling stock and even staff?

There might under these circumstances of operation by the concessionary, assisted by the main line, be various solutions in individual instances.

We should be most grateful if you would expound any with which you are familiar and the circumstances which gave rise to such solutions.

We would further beg you to inform us what legal enactments control your concession.

[625 .611]

SUPPLEMENT TO THE REPORT

By Mr. PLOCQ,

INGÉNIEUR CHEF DE L'EXPLOITATION
DES RÉSEAUX DE LA SOMME ET DU NORD DE LA SOCIÉTÉ GÉNÉRALE DES CHEMINS DE FER ÉCONOMIQUES FRANÇAIS.

GREECE.

The Greek North Western Railway Company has supplied us with some interesting information on the subject of railways in Greece.

There are 1,155 kilometres (718 miles) of railway in Greece, including 1,000 kilometres (620 miles) with a gauge of 1 metre (3 ft. 3 3/8 in.) and 52 kilometres (32 miles) with a gauge of 0·75 metre (2 ft. 5 1/2 in.)

Except the larger-gauge line, Piraeus-Athens-Larissa frontier, all of them can be considered as local lines.

Up to 1880, the State granted concessions with lump-sum subventions of 20,000 francs per kilometre (£1,287 per mile). The Thessaly, Piræus, Nauphies, Patras, Pyrgos lines were built in this way.

These lines and the small Laurium railway were operated by the concessionaries.

But the State, in order to accelerate the development of the railway system, decided to extend it itself and to lease the working. This resulted in the construction of the North Western lines, Missolonghi, Agrinion, which will be extended to Arta, the frontier of Epirus, and of the Central Peloponesian line, Myli, Tripolis, Kalamata, Kyparissia, which will be extended to Sparta.

As a rule, the operation of the line is at the cost, charge and risk of the operator; but losses are repaid out of the yield of subsequent years, so that it forms a sort of joint undertaking, as the company states.

In order to avoid complicated accounts and to protect itself against risks, the State as a rule adopts for the working expenses the formula

$$4{,}000 + \frac{R - 4{,}000}{2},$$

this formula includes the working expenses, the cost of maintenance of the line, and the cost of upkeep and renewal of the rolling stock. Any surplus is paid over to the State.

In several cases, the operator was also the contractor who built and equipped the line.

The Greek North Western Company considers that the system adopted is favourable both to the State and to the operator.

*

SECTIONAL DISCUSSION

Meeting held on 5 July, 1910 (morning).

MR. BEHRENS, PRESIDENT, IN THE CHAIR.

The President. (In French.) — I call upon Mr. Plocq kindly to give us a summary of the report he has drawn up about question XVIII.

Mr. Plocq, *reporter.* (In French.) — Gentlemen, to begin with I must request you to accept my apologies; I am not accustomed to public speaking, and, moreover, men more competent than I could certainly have drawn up a better report on this very delicate question.

According to the practice of the Railway Congress, I must limit myself to a very short summary of my report and then read out the conclusions. In the first place, I had to refer to the authoritative reports presented to the last session by Messrs. Colson and Ziffer, who described the state of the law in the different countries of Europe and America. I next thought it necessary to give a summary of that legislation. I added particulars about the alterations which have been made or are going to be made in the legislation of the different countries. I mentioned Spain where a complete law concerning light railways has been enacted, which seems, however, to have produced no results, as I have received no answer from that country.

In France, some years ago, a bill was brought forward by Mr. Barthou, minister of public works, modifying the act of 1880.

Mr. Colson's earlier report sets forth the situation in a very clear way and shows what modifications should in his opinion be introduced in the formulæ. He specially urges that in the working formulæ the train-kilometre should have a sufficiently great coefficient to make the operator have an interest in increasing the number of trains with a view to the development of traffic.

Some modifications have also been introduced in the Italian law; they concern the sums which can be placed every year at the disposition of the light railways.

After giving a sketch of the history of the subject, I proceeded to the subject itself. I drew up a detailed list of questions which you can find at the end of my report; they define the points about which information is desirable. Unfortunately the answers which I have received do not

always strictly apply to the questions asked.

I received very detailed information from Austria and Hungary. In each of those countries the subject is treated from a special point of view, as the State shows a growing tendency to undertake the operation of the light railways. I need hardly mention the country in which the problem of light railways is thoroughly worked out : I mean Belgium. Mr. de Burlet has explained in several reports how the Belgian National Suburban Railway Company is managed, with leases and working concesssions to private parties, to communes, etc.; but as regards the question such as set, I have found few details. Even from France where the working formulæ play such an important part as regards light railways, there have been few or no answers. It seems that leasing has given good results, but no details are given about the formulæ. From Germany, where there are many light railways, where the provinces assist in building them and where there are lessees and important firms, such as the firm Lenz, who operate a large number of railways, I received no answer; I was even given to understand that they did not wish to give answers.

Under these conditions, it is useless to lay stress on the figures which I have quoted.

To sum up, Gentlemen, I do not think I can do better than read out to you my conclusions. They run as follows :

Under the laws existing in each country, light railways have taken and are every day taking a greater development in all the countries where there is a main-line system forming a close network. England and the United States are, however, exceptions. The situation is not materially different from that expounded in 1905 by Messrs. Colson and Ziffer.

It is difficult to answer question XVIII such as it has been formulated by the Congress, and to give the results of the different systems enumerated in operating light railways.

Many administrations have sent no information. More especially have we received no answer from Prussia and Germany; here we can only record that the operation is by private enterprise. In France, the authors of the answers sent to us have not given any definite answer. We have only received really clear and concise answers from Belgium, Austria and Hungary. The formula of the *Société nationale des chemins de fer vicinaux*, which has produced such happy results in Belgium, is so well known that it is unnecessary for us to draw attention to it. In Austria and in Hungary, we have operation by the State. In Hungary, the Minister informs us definitely that working by the State involves a loss of 10 million kronen (£416,000); and this is the subvention necessary for establishing the light railways.

Under these conditions, we will not undertake to draw up any conclusions. At most we will allow ourselves to formulate a personal appreciation.

Everything concerning concessions was expounded by Mr. Colson to the 1905 Congress, and has been repeated in the preamble and the annexes of the bill concerning light railways brought before the Chamber of Deputies of France. Mr. Colson expounded, with his great authority, how important it is to pay attention to the factor train-kilometres, so as to induce the operator to develop traffic But once this has been said, nobody ventures to state what the result of the formulæ in use is, or to lay down other complete ones.

To us, this is a consequence of the economic transformation which results, in every country, from the new social conditions.

It is necessary that the formula of operation should allow the operator to live; it is at present very difficult to find a satisfactory one, as expenses are continually growing. We are not far from thinking that the solution to be preferred is that of contract working as described by an Austrian company.

Mr. Campiglio, *vice-president*. (In French.) — I will supplement, as regards Italy, the information given by Mr. Plocq.

In Italy, an act of later date than that mentioned by Mr. Plocq has raised the subventions for seventy-year concessions to 8,000 lire (£515 per mile) and for fifty-year concessions to 9,100 lire (£586 per mile).

If in spite of this capitalists, and especially those who are learned in railway matters, have kept aloof, this is because the contracts provide that the government takes too great a share of the gross receipts starting from a certain limit, which is fixed in the contracts in each individual case.

This share generally varies between 30 and 35 per cent.

Moreover, another article of the act settles that the State participates in the net profits, its share being generally 50 per cent of the net profits exceeding 5 per cent on the capital. It follows that as soon as the share of the gross receipts begins to become due, the operator, instead of benefiting by the growth of the traffic, loses money, and the more the traffic grows, the greater his loss, as the working coefficient of lines with little traffic amounts to about 90 per cent in Italy.

The Italian Railway Union had clearly foreseen what has happened, and when the bill was published it drew attention to the serious consequences which would result. But the ministry and the parliament considered the protests as made purely in the interests of the concessionary railway companies, and having but a mediocre knowledge on the subject, they did not even succeed in grasping the evident meaning of some examples which had been worked out in order to make the matter clear. Moreover, several concessions had previously been accepted by the delegates of provinces (not less ignorant of such matters), and this fact seemed to the government the best proof that the protests were not justified.

Now events very quickly began to show that the protests were well-founded. The province of Bergamo, which holds the concession for the electrified railway line in the valley of Brembana, has already found itself in a very critical position, because its traffic has increased enormously and has exceeded the limit at which the operator begins to have to pay over to the government part of the gross receipts.

The same applies in Italy to the tramways. The old act provided for a subvention of 2,000 francs per kilometre (£128 per mile). But here again the same condition comes into play: as soon as the receipts exceed a certain limit, the concessionaries must pay 30 to 40 per cent of the gross receipts to the government. Consequently, as the average working coefficient of the tramways is 75 per cent, as soon as the limit is attained the concessionaries have no further interest in developing the traffic.

Something might also be said about certain other conditions which prevent suburban lines and tramways from being worked more economically, but that

would necessitate going into too many details.

Mr. Machowetz, Austrian State Railway. (In German.) — I will allow myself to refer briefly to the financial subvention granted in 1908 to the local lines by the administration of the Austrian State Railway. It seems to me necessary to give this information in order to make it possible to draw a conclusion as to the magnitude of the local railways in Austria and as to the extent of the financial subventions given by the State.

In 1908, there were one hundred and eighteen local lines operated by the State, having a total length of about 4,400 kilometres (2,734 miles). Of this, about 1,900 kilometres (1,180 miles) belong to local lines enjoying State guarantees, that is to say, to which the State guarantee the interest on the preference capital.

The President. (In German.) — Those figures are in the report.

Mr. Machowetz. (In German.) — No sir, they are not there.

The President. (In German.) — Excuse me, you will find them in the report on page 15.

Mr. Plocq, *reporter*. (In French.) — The honourable gentleman states that the figures given in my report refer to the end of the financial year 1907, while the figures he is giving refer to the end of 1908.

Mr. Machowetz. (In German.) — Thus out of this whole length, 1,900 kilometres (1,180 miles) (about 41 per cent) of the local lines are lines guaranteed by the State, and in fact the State paid to these local lines in 1908, on account of these guarantees, the sum of 5,700,000 kronen (£237,120). Moreover, the State has taken over to its own account about 600,000 kronen (£24,960) for operating local lines which are operated by contract or which have a clause for postponement of working expenses, so that in 1908 the State contributed altogether 6,300,000 kronen (£262,080).

Out of the one hundred and eighteen local railway companies, seventeen gave very good results and the return on the capital invested generally reached 4 per cent or came very near this. Only seven showed a deficit, with receipts lower than working expenses. In 1908, the coefficient of working of all the light railways operated by the State was 56 per cent. But in 1909, it rose to 60 per cent owing to the increases in pay and in the price of materials.

The President. (In German.) — You have only spoken about twenty four companies; how are matters with the other ninety four?

Mr. Machowetz. (In German.) — The results vary. Some are good, others less good, etc. I have only mentioned the best and the worst. In the conclusions relating to question XVIII, it will be remembered that Mr. Colson proposed in 1905 that in the agreements relating to concessions the number of train-kilometres should be taken as an important factor in the working results. Now I do not quite see what this means. Is it a question of foreseeing a given number of train-kilometres or else of fixing the limit of the expenses according to the

number of train-kilometres? The conclusions only give me imperfect information about this point. The reporter says :

" Mr. Colson expounded, with his great authority, how important it is to pay attention to the factor train-kilometres, so as to induce the operator to develop traffic. But once this has been said, nobody ventures to state what the result of the formulæ in use is, or to lay down other complete ones."

I do not quite understand that phrase. Is it necessary to fix in the working formulæ the annual mileage expected, in train-kilometres, or else fix a unit rate per train-kilometre as limit of the working expenses?

The President. (In French.) — Can you explain this, Mr. Plocq?

Mr. Plocq. (In French.) — I think that the honourable member means that part of my conclusions which refers to what was said by Mr. Colson at the 1905 Congress; but I do not exactly understand his question.

This is how matters stand : when a concession for a railway is granted to somebody and the latter receives a guarantee from the State, the departments or the provinces, one says to that concessionary, you must calculate your expenses according to a given formula; now the first formula was :

k (*k* being a fixed amount) plus a fraction of the receipts.

For instance, the concessionary was told : you shall be entitled to 2,000 francs (£128 per mile) plus three-tenths of the receipts. If the latter amounted to 3,000 francs (£193 per mile), the concessionary was entitled to the constant 2,000 francs (£128 per mile) plus three-tenths of the receipts, that is to 2,900 francs (£186 per mile) altogether.

The act of concession stated that the concessionary must run, for instance, three trains per day in each direction. It is evident that if the traffic grew to such an extent that the goods traffic could not be carried by the existing trains, it was necessary to run additional trains.

Now as soon as the concessionary increases the number of trains, he incurs an expenditure which increases at once, but for which no allowance is made in the formula. Mr. Colson stated that under these conditions a factor should be introduced to allow for the train-mileage. I will explain. If for instance, the formula says three trains in each direction, over a length of 1 kilometre (0·62 mile), that gives 6 train-kilometres (3·7 train-miles). If another is added in each direction, that gives 8 train-kilometres (5 train-miles) per day. Well, what Mr. Colson says is this : in the formula, insert a term representing the number of train-kilometres multiplied by a certain coefficient, so that if one train more is required per kilometre, one has a sum of 30, 40, 50, 60 or 70 centimes (4·63, 6·18, 7·72, 9·27 or 10·81 pence per mile), for instance. It is for the concessionary to settle with the grantor the fixed sum he is to receive, plus the percentage of the receipts, and finally the amount he is to receive per extra train-kilometre. The grantor in fact says to the concessionary : if you put on more trains, I will pay you for them according to the conditions agreed.

Mr. Machowetz. (In German.) — In other words, the fixed amount, the constant if you like, never varies, even when the mileage is greater?

Mr. von Ziffer, *vice-president.* (In German.) — No, there will be an extra amount for the mileage beyond the fixed limit.

Mr. Francis Level, Anvin-Calais Railway, France. (In French.) — Mr. Colson was struck in his investigations by the fact that the two-term formula in certain cases led to a conflict of interest between the grantors and the concessionaries; that is why he tried to discover another formula. It must, however, be noted that Mr. Colson has not confined his attention to formulæ of two and three terms; he has also investigated the four-term formula, which includes a ton-mileage term. The grantor and the concessionary must try to come to an agreement as to which formula is the best to apply in any individual case, so that the interests of both parties and the interests of the public should always, as far as possible, point in the same direction.

Mr. de Burlet, *vice-president.* (InFrench.) — All that is very complicated. I think that we in Belgium have formulæ which are both simple and rational.

Mr. Machowetz. (In German.) — I think that in such theoretical matters, formulæ do not go very far; that is only the case in France.

I also wish to say a word about the question of leasing light railways, with a share of the net profits. I think it is difficult to establish any general rule and that every local line must be considered by itself. Other methods of calculation can also be found, for instance, by totalizing the mileage or by taking the percentage of receipts. But it is difficult to establish a general rule.

In conclusion, I may mention that a new law concerning the local railways of Austria is now being worked out, but as it is not yet settled I am unable to give details.

Mr. de Burlet. (In French.) — Has the draft of this law been published?

The President. (In French.) — No.

Mr. von Ziffer. (In German.) — The two chambers of the Reichsrat have recently passed a new act concerning secondary railways, coming into force 8 August 1910. It contains some improvements on the old act of 31 December 1894 and must hence be considered a step in advance; but it only takes into consideration to a slight extent the proposals submitted by the Austrian Union of local railways and by the Association for promoting local lines and tramways, proposals which had the object of inducing capitalists and savings banks to interest themselves more in undertakings of this kind. In this act the fiscal point of view plays a preponderating part. I may add that also in Rumania has a new act been passed. This enacts that all standard-gauge lines intended for the public service shall receive a subvention of 1,500 francs per kilometre (£96 per mile) for thirty consecutive years, no matter what the yield of the lines may be; moreover, the land belonging to the State is given free of charge, and finally, the act grants important facilities in construction and operation.

Colonel Suarez, Ministry of public works, Bolivia. — There are 1,128 kilometres (700 miles) of local railways in the State of Bolivia. These railways date back to 1892. The results are really marvellous; dividends of 17·5 per cent are paid.

The concession was granted in 1892 by the Bolivian government to an English company, the State giving a guarantee of 6 per cent. This guarantee has never been called upon because, as I have already stated, the results have been very excellent. This railway goes up to a height of 14,000 feet. The country is very mountainous. This line is not of metre (3 ft. 3 3/8 in.) gauge like the other railways, but it will be so in a few years. The shares now stand at double their original value.

Mr. Losseff, Home Railway Union of Russia. (In French.) — What are the steepest gradients and the sharpest curves?

Colonel Suarez. — At the moment I cannot tell you what gradients and curves there are, but I can give you that information later on.

Mr. de Burlet. (In French.) — Are those lines operated by the concessionaries themselves?

The President. (In French.) — Yes.

Mr. Bello, Portuguese National Railway Company. (In French.) — I place on the table a note about the narrow-gauge lines in Portugal. If you like, I will read it.

The President. (In French.) — Certainly.

Mr. Bello, (In French.) — This is the note in question :

In Portugal, 1 May 1910, there were 450 kilometres (280 miles) of narrow-gauge lines in operation :

State :			
Line from Livracão to Amarante (1 metre [3 ft. 3 3/8 in.] gauge).	13 kilometres	(8 miles).	
Line from Regoa to Vidago (1 metre [3 ft. 3 3/8 in.] gauge).	77 —	(48 —).	
			90 kilometres (56 miles).
National Railway Company :			
Line from Tua to Braganza (1 metre [3 ft. 3 3/8 in.] gauge).	135 kilometres	(84 miles).	
Line from St. Comba Dão to Vizeu (1 metre [3 ft. 3 3/8 in.] gauge).	50 —	(31 —).	
			185 kilometres (115 miles).
Guimaraes Railway :			
Line from Trofa to Fafe (1 metre [3 ft. 3 3/8 in.] gauge) . . .	...		56 kilometres (35 miles).
To carry forward. . .	...		331 kilometres (206 miles).

Brought forward. . .	...	331 kilometres (206 miles).
Oporto, Povoa and Famalicão Railway :		
Line from Oporto to Famalicão (gauge 0·90 metre [2 ft. 11 1/2 in.])	58 kilometres (36 miles).	
Line from Oporto to Leça (gauge 0·90 metre [2 ft. 11 1/2 in.]). .	6 — (4 —).	
		64 kilometres (40 miles).
Vouga Valley Railway :		
Line from Espinho to Albergaria-a-Velha (1 metre [3 ft. 3 3/8 in.] gauge)	...	55 kilometres (34 miles).
Total. . .	...	450 kilometres (280 miles).

The lines from Oporto to Povoa and to Famalicão have a gauge of 0·9 metre (2 ft. 11 1/2 in.); all the others are metre (3 ft. 3 3/8 in.) gauge.

The cost of construction of these lines averaged 100,000 francs per kilometre (£6,437 per mile).

At the end of 1907, altogether 336 kilometres (209 miles) were in operation, 43 (27 miles) of which belonged to the State and 293 (182 miles) to companies.

The receipts and expenses per kilometre in 1907 were :

Traffic receipts	471,718,272 reis (£104,826.5*s.* 7·9*d.*);
Per kilometre (per mile).	1,403,925 — (£502.1*s.* 6·86*d.*);
Expenses	277,759,192 — (£61,724.5*s.* 3·6*d.*);
Per kilometre (per mile).	826 664 — (£295.12*s.* 8·7*d.*).

The working coefficient averaged 58·88 per cent.

These lines carried :

Passengers.	1,465,914.
Quick-freight goods.	10,194 tons (10,032 English tons).
Slow-freight goods	219,286 — (215,822 — —).

Mr. de Burlet. (In French.) — Is the cost of rolling stock included in the cost of construction you have named?

Mr. Bello. (In French.) — Yes, everything is included. It is a question of total outlay per kilometre. This, I repeat, averaged 100,000 francs per kilometre (£6,437 per mile), rolling stock included.

Mr. de Souza, Portuguese State Railway. (In French.) — Here is some information about the light railways of my country. They help to confirm the conclusions in Mr. Plocq's excellent report.

I am going to show you the difficulty of arriving at a sufficiently flexible formula for facilitating the development of light railways.

At first concessions were granted without any subvention.

Two companies are exceptionally placed and one even pays a dividend of 6 per cent. One is a suburban line; the other has a very large traffic in a distant district where there is a considerable population. Accordingly, these cannot be taken as typical.

In smaller places where there are few inhabitants, the assistance of the government is absolutely necessary.

Concessions have been granted for nearly 180 kilometres (112 miles) of lines which are in operation; but with the existing formula, the greater the traffic the greater the loss.

That is why attempts are being made to arrive at another formula.

In the first place, as it was a question of a rather mountainous country where there is a broad-gauge main line which ought to have several feeders of metre (3 ft. 3 3/8 in.) gauge, a given share was granted, and exemption from tax, custom duties, etc., was also granted; but as there was no fixed guarantee, this formula did not give encouraging results.

There is only one short section forming an extension of a line already constructed, which was built under these conditions.

Some time later, another plan was adopted : a guarantee of 5 per cent on a capital of 5,000 francs for the construction was given; but the guarantee of the government never exceeds 3 per cent.

One of the lines found great difficulty in raising the capital, but it is on the eve of success.

As the State operates lines running through an important and very undulating district, and as a broad-gauge line would be too expensive, the metre (3 ft. 3 3/8 in.) gauge has been adopted for the feeder lines.

The State is at present building several lines and has fixed rather flexible conditions; but one is too much affected by the proximity of the broad-gauge line.

In short, construction and operation are expensive.

In the districts where it is difficult to raise capital for building light railways, it would be preferable to grant a reasonable percentage and to fix a well thought-out formula for the operation.

It is necessary to make it to the interest of the operator to increase his receipts.

We have nearly 450 kilometres (280 miles) in operation, the formulæ varying widely, and we are still undecided as to the best way of developing these lines.

As for tramways, we hardly have any. An act has been passed to promote their construction; but no subvention is given, only the permission to utilize the highways, and that only under condition of maintaining them.

Taking it altogether, this act has not produced any good results.

Mr. Waechter, Vering & Waechter Company, Germany. (In German.) — I wish to explain why Germany sent the Congress so little information about the subject of light railways. It is due to the fact that none of the companies operating such lines belong to the Congress. My company also has nothing to do, except incidentally, with what we call minor railways.

I may add that the adoption of a special indemnity per train kilometre covered has given good results in Germany, particu-

larly if with increasing gross receipts there is a decreasing scale for the working expenses.

Mr. Plocq, *reporter*. (In French.) — I knew quite well that the German private companies operating the light railways did not belong to the Congress; accordingly I tried to obtain information by applying to those companies direct, but they preferred to keep reserved.

Mr. Van Nierop, Dutch Tramways. (In French.) — All those companies which publish reports are joint-stock companies, are they not?

The President. (In German.) — Do these reports exist?

Mr. Waechter. (In German.) — They are published in certain papers (1).

Mr. de Burlet. (In French.) — But the reports and balance-sheeets of such joint-stock companies do not as a rule contain much information from the technical point of view; they give hardly anything except financial information. Anyone who wanted, on the basis of these reports only, to obtain information about technical questions and leasing contracts, would be very badly informed.

Mr. Van Nierop. (In French.) — But that is what we are considering.

Mr. de Burlet. (In French.) — I beg your pardon; we are considering working formulæ and not financial questions, which are the sole object of the reports of private companies.

Mr. Van Nierop. (In French.) — If there are any subventions, they appear in the reports.

Mr. de Burlet. (In French.) — I repeat that if only those documents were available, that would be a very difficult investigation for anybody undertaking it.

Mr. Donker Duyvis, Semarang-Cheribon Tramways, Dutch Indies. (In German.) — At page 24 of his report (1), Mr. Plocq states that the working expenses of the light railways in Java are lower than in the case of main-line railways, but that these undertakings are far from all showing good results. However I know some to which this does not apply. Accordingly I am able to state that the great majority of these lines give very good results, and so prevent Mr. Plocq's words from giving a wrong impression.

I am manager of the four companies mentioned on page 9 (2). It is said that these four important companies, although quite distinct, have a joint management.

I had no intention of taking part in this discussion, but I wish to state that in 1909 these four companies paid dividends of 10, 9, 9 and 5 per cent respectively.

Of the eleven companies mentioned (the chief are in Java), there are only three or four which pay no dividend, but the others pay very fair dividends.

These results are due not only to the

energy of the operators, but also to the legislative provisions issued in 1893 by the government of the Dutch Indies, which are mentioned by Mr. Plocq in his report and which have made possible the extensive development of the light railways, to the great advantage of the country generally.

Mr. Plocq himself states that in 1895 there were nearly 2,000 kilometres (1,240 miles) of light railways in existence, while there were far fewer before more liberal regulations had been issued by the Dutch government.

It is hence only just to correct, as regards the Dutch colonial government, the conclusions of Mr. Plocq's report.

Mr. Plocq. (In French.) — I certainly did not intend to make criticisms and to say that the lines on the island of Java do not give good results; but I have recorded that a certain number exist which do not pay. The chief lines which form a large jointly-operated system pay; that is the truth.

The Batavia tramways are magnificent lines, but there are some which do not pay (1). Thus I did not want to make any criticisms whatever.

Very interesting information has been sent to me : a splendid album with views of your lines, and I was particularly struck by the fact that these lines, although quite distinct, had one and the same management and that the employees were bound to serve sometimes on one line, sometimes on another. That is a notion which we eventually propose to turn to our advantage. (*Laughter.*)

I have a small communication to make. After my report had been printed, that is to say after April, there was sent to the Permanent Commission, at Brussels, a very complete report, not from the point of view of the results of working, but from the point of view of the position of the Greek railways. I have made a summary of it which has been published as a supplement to my report (1).

Mr. de Burlet. (In French.) — Mr. Plocq, in his report, has given a flattering notice about the organization of light railways in Belgium, for which I thank him. He refers his readers to the reports which have already been published about the Belgian system, but as several of our colleagues who are here have perhaps not had any opportunity of reading those reports, I ask your permission, in order to meet the wishes of the President, to give you a brief account of the principles on which the organization of local lines in our country is based.

Belgium is, as regards iron roads, really in a privileged position. At the present time we have in Belgium, in our small country, 4,600 kilometres (2,858 miles) of main railroads, that is to say, of railways of general interest. This represents 15·5 kilometres per 100 square kilometres (24·9 miles per 100 square miles). England, per 100 square kilometres (per

(1) Note by Mr. Donker Duyvis : there are two at Batavia. One is an electric line which does not pay at all; the other is a steam line (locomotives without fire-box) which gives good financial results, paying 9 per cent in the last financial year for which a report is published.

(1) See *Bulletin of the Railway Congress*, June 1910 (1st part), p. 2707.

100 square miles), has 11·5 kilometres (18·5 miles) of railways, Germany 10 (16·1 miles) and France 8·5 (12·9 miles). Most of the main railroads in our country are operated by the State, the State having bought up nearly all the lines for which concessions had been granted; it has also built others itself. Thus at present out of the total 4,600 kilometres (2,858 miles) of main railroads, only 360 kilometres (224 miles) are still operated by private companies.

As regards railways of local interest or light railways, which we call in Belgium suburban railways, they are under quite special laws.

In 1885 an act was passed creating a central administration charged with everything affecting light railways in our country. This is the Belgian National Suburban Company. It has a monopoly; that is to say if any private parties ask for a concession for a light railway, the company has the preference for a year. If during that time the company has not asked for a concession for that line, the government can grant it to those private parties.

But what is of great interest in our organization and what in my opinion has been the cause of its success, what has enabled it to develop so extensively in a short time, is the way in which the capital required for the construction of the line is raised, with the intervention of the State, the provinces and the communes, by means of the issue of shares. These three great organizations exist in nearly all countries in Europe : the central authority, the provinces (called departments in France) and the municipalities. The capital is thus provided by these three sets of public authorities, eventually with the assistance of private parties. The State finds half; it is not compelled to do so by law, but has itself fixed this amount at 50 per cent, and it cannot legally go beyond this. The provinces and the municipalities subscribe the rest of the capital.

The President. (In French.) — In equal shares?

Mr. Burlet. (In French.) — No, this varies. This point is also left undetermined in the act; some provinces take one-third, others one-fourth, and the communes the remainder. If the province gives one-third, only one-sixth is left for the communes to subscribe; if the province gives one-fourth, the communes also give one-fourth.

With us there is question neither of guarantee of interest nor of lump-sum subvention. The State, the provinces and the communes subscribe for shares. I will assume a line costing a million of francs (£40,000); the State takes 500,000 francs (£20,000) worth of shares, the province 250,000 francs (£10,000) and the communes the same amount. The latter have to arrange between themselves, in accordance with principles not fixed by the act, and which could not so be fixed, as to the division of the 250,000 francs (£10,000). There is, I repeat, neither subvention nor guarantee of interest, so that once the line has been built, the three branches of the public authorities are interested, *pro rata* according to the shares they hold, in developing the traffic and in seeing that the line produces the maximum of services and receipts which one can except from it.

A delegate. (In French.) — The line?

Mr. de Burlet. (In French.) — Yes, each line forms a separate undertaking, each has its own separate accounts. A commune which is interested in a given line has nothing to do with any other line in which it does not hold shares. Thus there are as many small companies as there are lines. By agreement of the shareholders, the capitals of several small lines can be combined together in one group.

The examination of schemes, the administration, the operation of the lines, the different sets of accounts are all looked after by the National Suburban Railway Company which manages these different departments. The development of the new system was very rapid. I reminded you when I began, that the act which definitely organized this system bears the date of 1885, and is accordingly twenty-five years old. This is the result we have arrived at : at the present time we have concessions for 4,500 kilometres (2,796 miles) of light railways. Thus you see that although the main-railroad system is already of very close mesh, yet we have managed to insert 4,500 kilometres (2,796 miles) of light railways.

The President. (In French.) — About as much as the main railroads.

Mr. de Burlet. (In French.) — That is so, as in Belgium there are 4,600 kilometres (2,858 miles) of main railroads.

These 4,500 kilometres (2,796 miles) of light railways for which concessions have been granted are not all finished; 3,750 kilometres (2,330 miles) are in operation and the other 750 kilometres (466 miles) are under construction. As soon as the concession for a line has been granted, the land required is bought, the specifications are drawn up and the works are commenced.

Besides the lines for which concessions have been granted, we have at present a number of others under consideration, and in a few years, including the schemes which are now being drawn up, we shall have altogether 6,350 kilometres (3,945 miles) of light railways, a very satisfactory result for a small country such as ours!

How do we operate these light railways? Here I return at once to the question we are considering. When our existence began, we decided, after very careful consideration of the question, not to undertake by ourselves direct, the operation of these lines which are scattered over the whole country. We thought it better to give leases to private companies. We are well satisfied with this system, and are fully convinced that if we had to centralize at Brussels, in our offices, the operation of these lines, about 170 in number, each of which has its own character and its own special needs, we should have had many difficulties, and that this system would have made operation much more costly. On some lines, the passenger traffic is very important, much more important than the goods traffic; others are above all goods lines; there are tourist lines and lines to holiday resorts; there are agricultural lines, industrial lines, seaside lines connecting the watering places along our coast; each of these lines requires special management which has to be learnt on the spot and which can be better applied if the operation is left to local groups. I regret that I have no time to elucidate this point, which is one of the most interesting features of our organization.

Of the 3,750 kilometres (2,330 miles) forming 150 different lines, we have leased 3,550 kilometres (2,206 miles) to operating companies. We ourselves provisionally operate, without intermediaries, about 200 kilometres (124 miles), and that on account of special reasons.

Private companies operate a very great part of our lines; I say a very great part, because I must tell you that the suburban lines in Belgium are operated not only by private companies; the operation of certain lines has been intrusted to a communal group. Certain municipalities which provided some of the capital have asked for the right of combining between themselves, and also, in certain cases, with the province, in order to undertake the operation of lines. At present, there are about 500 kilometres (310 miles) the operation of which is entrusted to communal groups. This is what we have called the *Société intercommunale* (intercommunal company) or the *Société intercommunale provinciale* (provincial intercommunal company); for, as I have already said, there are groups in which the province, which also provided some of the capital, also wished to be interested. It follows that on certain lines the operation is carried out by the company formed by the province and the communes. It is to this small company, which has such a special constitution, that the National Company has entrusted the operation of lines, under certain well-defined conditions.

Thus the proprietors of half the capital, as the State does not concern itself with the operation (it has decided up to the present not to participate in the operation of the suburban lines), it is I say these proprietors of half or a quarter of the capital, who in this intercommunal company, with or without the help of the province, which does not everywhere participate in this organization, it is the communal groups or the provincial communal groups which have undertaken the operation of a certain number of lines.

We also have in Belgium some lines operated by companies holding main-railroad concessions. (In Belgium, there are still about 360 kilometres [224 miles] of main railroad belonging to private companies, the rest being operated by the State.)

The Belgian Northern Railway in particular, an offshoot of the French Northern Railway, has to our great satisfaction undertaken the operation of a group of about 250 kilometres (155 miles) of suburban railways which connect with the main railroad. Gentlemen, you know the Belgian Northern well enough to know that when we entrusted the operation of the suburban lines to such an experienced, trustworthy and capable body, we could be certain of its being in very good hands.

Accordingly this is our system: we plan and we build the lines, we supply them with stock and we lease the operation to private or to intercommunal companies.

Gentlemen, I do not wish to begin the examination of a question which is not on the agenda and which, moreover, has already been thoroughly discussed at other sessions of the Congress; I mean the working formula we have adopted. It would occupy several meetings to examine and discuss this subject. We have naturally changed about a little, felt our way at the start, and did not straightway find

the best formula. I have often had the opportunity of discussing this question with one of our French colleagues, Mr. Colson, whose great authority and incontestable knowledge of this subject has frequently been appealed to, and with justice, and I think that I agree with him when I state that the formula we are at present applying in Belgium quite satisfies the desiderata which have frequently been enunciated. We wish the operator to be interested in the growth of the receipts. The arrangement must not be such that at a given moment the operator can say to himself : " It is to my interest that the railway receipts should not increase any more. " Such a condition would be absurd and against the general interest. A formula which would entail such a condition would be condemned without need of appeal. But I cannot go into details about this question of the working formula to adopt in the leasing contract and I return to the general organization of the Belgian suburban railways.

Certainly we felt our way, and changed about a little, before we succeeded in putting on its legs the system now existing, and which we think is quite satisfactory. It has stood all tests, and having ascertained what has happened in other countries, I think I may declare, without any endue criticism, that the Belgian system, of associating the three different sets of public authorities in order to develop light railways, is really practical and prolific. .

We were told a little time ago of what has happened in Portugal : at first concessions were granted for lines without any intervention of the public authorities. What happened? Why, only two lines were constructed. It is easy to foresee that with such a system of leaving the construction of light railways wholly to private undertakings, only very remunerative lines will be built, yielding high dividends, 6 per cent or more.

After these two lines had been built, which were as we are told, under exceptional circumstances, there was a standstill in Portugal. Private enterprise did nothing more and it was necessary to obtain the intervention of the State. This took several forms : lump-sum subventions, guarantee of a minimum rate of interest on the capital outlay, guarantee of a minimum for the working expenses.

I am opposed to these lump-sum subventions (I have stated my reasons elsewhere), and especially to the guarantees of minima, which have great disadvantages.

I have no time to set forth my arguments about this subject. I will merely remind you that France has had some very unpleasant experiences in this way. I have had interviews with very competent French engineers to discuss this point, interviews which have been very instructive to me. Besides, there are the results :

That I am opposed to a guarantee of interest on the capital outlay, and also to a guarantee of a minimum for working expenses, is above all, because this formula tempts the builder of the line unduly to inflate the capital outlay, and the operator of the line to inflate, also unduly, the working expenses, and because such a system compels the authority granting the concession for the line to undertake many checking and controlling operations, of a complicated, difficult and disagreeable

character, which can only result in numerous disputes.

In my opinion, of all these systems the best is intervention, in the shape of subscribing for shares.

Gentlemen, it is always a delicate matter to praise matters in one's own home and to seem to say : " *Prenez mon ours* " (1). (*Laughter.*) But I think that I may assert that our Belgian system has proved its merits and that I can with every confidence, recommend it to those who are still seeking the best formula for developing light railway systems, which have so aptly been called the brooks which must feed the rivers, in other words bring to the main railroads new elements of prosperity and of traffic. (*Prolonged cheers.*)

Mr. von Ziffer. (In German.) — I wish to point out a mistake in the report. It concerns Rumania.

The act of 1898 was superseded by a new act passed, if I am not mistaken, in 1907. This act has the object of facilitating the construction and operation of light railways in Rumania. The act mentioned by the reporter did not result in helping the construction of a single light railway in Rumania. That is why parliament passed a new act. According to this, every concessionary building a standard-gauge local railway receives a subvention of 1,500 francs per kilometre (£97 per mile) during thirty consecutive years, no matter what the net profit of the railway may be; moreover, there are a certain number of working facilities, and land belonging to the State is given free of charge. I think that I must give you this information because it is extremely interesting to know that a country gives such financial assistance to help the development of light railways. The act has already had as result the building of several local lines. I myself have worked out the scheme for one of these light railways, 76 kilometres (47 miles) in length. A company was formed which by virtue of that act receives a subvention, and the railway has now been in operation for a year. This is quite an exceptional case. In fact I do not understand why, independently of any net profits or even of high profits of a line — which may distribute dividends of 6 to 8 per cent, the company should receive, during thirty consecutive years, this subvention of 1,500 francs per kilometre.

Mr. de Burlet. (In French.) — I omitted to give you some figures which will perhaps interest you, as supplementary to the particulars I gave. We have at present invested in light railway enterprises a capital of over 303 million francs (£12,120,000). The net revenue, the mean dividend of the last few years, has been 3 per cent; this is the interest received by the State, the provinces and the communes in their capacity of shareholders.

If we have good lines, we also have mediocre ones from the point of view of the receipts, for certain parts of Belgium have no great population, nor much industry nor commerce. These are in particular the hilly districts and those where the soil is not very fertile. But what I can assert is, that all the lines render the

(1) Literally " take my bear ". A quotation from a vaudeville by Scribe and Saintine. A somewhat equivalent English phrase would be " buy my white elephant ". (*Note by translator.*)

public very great services and that the administrations do not regret the slight sacrifices they have had to make in order to ensure the building of these iron roads. Two figures to finish up with :

In 1909, we carried 75 million passengers and 5 millions tons of goods (500,000 wagons of 10 tons each).

Mr. von Ziffer. (In German.) — I congratulate Mr. de Burlet on the brilliant results obtained by the Belgian National Suburban Railway Company. I am in favour of the system of leasing based on formulæ fixed by joint agreement with the operator and varying according to local conditions, while as far as possible safeguarding the interests of the owners and of the operators of the railway. The leasing system adopted by the Belgian National Suburban Railway Company seems to me worth imitation.

Mr. Van Nierop. (In French.) — The dividend is not the same on all the lines?

Mr. de Burlet. (In French.) — No, I have given the average dividend; each line has its own capital and keeps separate accounts.

Mr. Van Nierop. (In French.) — Are there then as many sets of accounts as lines?

Mr. de Burlet. (In French.) — Yes, each line has its own accounts. If our last year's report interests Mr. Van Nierop, I shall be very pleased to let him have it and he will be able to find in it the practical and detailed application of the rules of which I have only indicated the general principles.

Contrary to what is the practice of purely private companies we strive — as we are more a public administration than a purely speculative company — to include in our report all information which may interest not only financiers, but also technicians, economists and administrators, in fact all those who are interested in the organization of the Belgian suburban railways, which has quite a special character of its own.

We keep separate profit and loss accounts for each line or for each group having a single capital.

Some pay dividends of 5 to 6 per cent; those are the good lines in the immediate neighbourhood of large towns or of well-populated and industrial districts. Others again pay more modest dividends, 2·5, 2 or 1 per cent.

In certain cases, if the line has cost much and a large capital has been sunk, it may happen that the first few years are bad; actually however there are only five lines on which the receipts do not cover the working expenses.

Mr. Van Nierop. (In French.) — Do all the lines have the same shares?

The President. (In French.) — Each line has its own shares.

Mr. de Burlet. (In French.) — The Belgian National Suburban Railway keeps all the accounts, but each line has its own shares, as I have already mentioned.

Mr. Van Nierop. (In French.) — Have shares already been sold?

Mr. de Burlet. (In French.) — No, the communes cannot sell their shares without authorization from the government.

*

That is, however, a general administrative rule : no commune, whether owning forests, lands, buildings, etc., can sell anything without authorization from the control authorities. The same is the case with any inscribed Government stock. Consequently, this also applies to the suburban-railway shares owned by the communes. But as I have already stated this is a general administrative rule, not one specially applying to suburban railways. The case however does not arise. Two things may happen : either the shares are very good and a suitable dividend is received, and then communes keep them because it is to their interest to do so ; or else the dividend is poor, and then the communes could not sell them if they tried; for they could only sell them below par, and they would lose the advantage resulting from the gradual growth of the traffic, which happens on the light railways just as on the main railroads.

I forgot to mention that private parties may also subscribe capital. Thus if a commune is not rich enough to subscribe for all its shares, it can apply to the landowners and manufacturers of the district. Out of a total capital of 303 million francs (£12,120,000) we have shares for hardly 4 millions (£160,000) — an insignificant amount — held by private parties.

The President. (In French.) — May they sell their shares?

Mr. de Burlet. (In French.) — Yes, they are shares to bearer. As soon as they have been delivered, the private parties can sell them; it is quite indifferent to the National Company whether they are owned by X or by Y.

The President. (In French.) — Does anybody else wish to address the meeting?

Gentlemen, I propose that we adjourn till this afternoon, at 2.30 p. m., in order to continue the discussion and put the conclusions of the report to the vote. (*Approval.*)

Meeting held 5 July 1910 (afternoon).

Mr BEHRENS, President in the chair.

The President. (In French.) — We will resume the discussion of question XVIII.

Mr. Girtanner, Federal department of posts and railways of Switzerland. (In German.) — You will allow me to add, to what has been said this morning, a few words relating to the conditions existing in Switzerland. As you can see from the table relating to Swiss railways given in the report, we have an extensive system of light or secondary railways in Switzerland. It includes standard-gauge lines and narrow-gauge lines. Most of the secondary railways are narrow-gauge lines, the gauge being 1 metre (3 ft. 3 3/8 in.). Very few lines have a gauge of less than 1 metre; with one exception, these are lines used solely by tourists and of no importance to commerce and industry. Out of 2,316 kilometres (1,439 miles) of secondary railways with movable motors, that is to say,

not including the cable railways, 718 kilometres (446 miles) are standard-gauge lines, 1,523 kilometres (946 miles) are metre (3 ft. 3 3/8 in.)-gauge lines; 61 kilometres (38 miles) have a gauge of 800 millimetres (2 ft. 7 1/2 in.) and 14 kilometres (9 miles) have a gauge of 750 millimetres (2 ft. 5 1/2 in.).

In Switzerland, the concessions for privately-owned railways are generally granted by the federal authorities, that is to say by the parliament. The federal government does not as a rule grant subventions to help the construction of light railways. An exception was made in favour of the system of the Rhetian Railway which opened to traffic the valleys of the Grisons canton. But owing to its extent and its economic importance, this system has more the character of a narrow-gauge main railroad than that of a secondary railway. The subventions received by the secondary railways are granted exclusively by the cantons and the communes. The ways of doing this are very variable. While formerly each case was a rule considered on its own merits, the growth of the secondary-railway system has given rise to a legal regulation of the cantonal contributions. In most cases the canton is compelled to contribute a certain subvention per kilometre towards the construction of the lines. Assistance in the shape of subsidies to help the operation is as a rule not granted except to enterprises which are in a precarious position, in the hope that results will improve. Besides the cantonal subventions, the communes also grant subventions, sometimes very considerable ones. The form the subvention takes is very variable. Sometimes it is a lump-sum subvention. Such was especially the case when the construction of secondary railways began. At present, the subvention is generally given in exchange for shares of the more or less deferred kind. These shares are only entitled to dividends after a given dividend, usually 4 or 6 per cent, has been paid on the debenture capital, if any, and on the ordinary stock. As a general rule, these subvention shares yield no return. It is true that in giving these subventions, the object aimed at is not so much any direct revenue, in the form of interest or dividends, as the economic benefit the enterprise will confer on the districts concerned. In order to complete this information, I may mention that it is not always that subvention shares are given in exchange for the financial assistance of the cantons and communes; in many cases also, ordinary shares are demanded in exchange for part of the amount contributed.

Besides the subventions towards the construction of the lines, the communes or cantons also grant, in some few cases, a guarantee of interest for the whole or part of the debenture capital. This system is fortunately only rarely adopted, and then generally only in cases where it is a question of the reconstruction of an undertaking which is financially weak. The sacrifices which communes, for instance, must make in such cases, are nearly always a very heavy burden on their budget.

Apart from subventions in cash, which are the only ones hitherto considered, there are also other such as the free grant of land required for the line, the supply of natural materials of construction, such as sand, gravel, stone, timber, etc. It is

above all the communes who try to facilitate the construction of a line by the help of such subventions.

The President. (In German.) — Also labour?

Mr. Girtanner. (In German.) — No, not labour.

In order to utilize a highway as roadbed for a railway, it is necessary to obtain the authorization of the owner of the highway, that is to say, the commune or the canton. The federal government exercises no authority in this direction; on the other hand, it has laid down that the conditions under which the authorities concerned authorize the utilization of the highways must be in opposition neither with the federal act of concession nor with the federal legislation.

The conditions under which the utilization of the highways by railway enterprise is authorized vary widely. Sometimes the authorization is granted without any charge, sometimes it is specified that as soon as the net profits exceed a certain rate, for instance 4 per cent, a certain amount, generally so much per kilometre, is to be paid for the use of the road. In many cases, the railways are bound to maintain the road, either only that part of it which is used by the railway, or over its whole width. Similarly, the removal of the snow in winter has often to be looked after, wholly or in part, by the railway; that is an onerous condition, particularly in mountainous districts.

The system of subventions towards the working expenses, mentioned this morning, is not applied in Switzerland, or at least only to a very limited extent. The construction and the operation of most of the secondary railways are generally in the hands of companies; the only exceptions are municipal tramways and certain small railways constructed and operated by the canton. It is under this regime, which has given good results under our Swiss conditions, that many light railways have been built which are of great importance as feeders of the main arteries of the traffic. In Switzerland, much still remains to be done from this point of view, in spite of the great extent of the light-railway system, and it is to be hoped that the efforts made will be continued energetically, especially as regards the construction of narrow-gauge light railways.

Allow me, in conclusion, to make a short remark with reference to a point mentioned in the report. It is not a correction so much as an explanation. You will find at page 11 of the report on question XVII [1], the remark that in Switzerland an order concerning the construction and operation of secondary railways was issued in 1906, which did not contain any simplification of the prescriptions which were then in force. If we read this remark, we are led to ask why the new order was issued. It is true that it includes few innovations of a practical kind; nevertheless it includes several new facilities. But it is above all of importance because it summarizes in a legal form all the regulations successively issued in order to meet practical requirements and will form, for the future, a solid legal basis which will enable the future and

(1) See also *Bulletin of the Railway Congress*, November 1909, p. 1345.

successful development of the construction and operation of secondary railways.

Mr. Forrest, Madras & Southern Mahratta Railway, British India. — The reporter of this section has not mentioned any of the 2 ft. 6 in. railways, in India, or the short feeder lines constructed out of capital raised by companies outside of the main lines.

The Gaekwar of Baroda has about 90 miles of 2 ft. 6 in., running through the fertile district of Gujerat, and earning over 7 per cent. The rates the small line charges, however, are in excess of these on the Bombay & Baroda Railway, which works the lines in question. The Maharajah of Gawlior has also constructed several miles of 2 ft. 6 in. and there is also the well known Darjeeling Line, which goes to that popular hill station.

The Government of India is also encouraging the construction of feeder railways to the main lines and they offer now liberal terms which attract the attention of natives, and encourage them to put their money into railway enterprize. It is said that out of the many millions of capital spent on Indian railways not more than about £50,000 is held in India. For these feeder lines, the government give land free and the main lines work and maintain them for 45 per cent of the gross receipts, and also give a rebate from interchanged traffic towards ensuring a dividend of 5 per cent; anything over 5 per cent is shared with the main line. The government have the right to buy the lines at the end of thirty years at not less than the cost price and not more than 20 per cent premium; the price between these limits being based on twenty-five times the average of nett receipts for the last three years.

My firm has raised capital for four of these feeders and they earn from 5 to 7 per cent; the capital is all raised, in India, in rupees.

Mr. de Burlet. (In French.) — At the end of the proposed conclusions, which are really more in the shape of a summary of Mr. Plocq's very interesting report, I read : " It is necessary that the formula of operation should allow the operator to live." I think everybody will agree with this. (*Laughter.*) " It is at present very difficult to find a satisfactory one, as expenses are continually growing. We are not far from thinking that the solution to be preferred is that of contract working as described by an Austrian company."

I shall be very grateful to the honourable reporter if he will kindly give us some explanations about these words " contract making ". I do not quite understand the meaning of this phrase.

Mr. Plocq. (In French.) — In the first place I wish to mention to you that I have expressed no personal opinion. I said in my report that I saw no way of arriving at a definite conclusion. It is certainly very difficult, seeing that expenses are continually increasing, to find a satisfactory formula; for in fact our expenses vary every day, and I think that is so in every country. They are always increasing and we cannot foresee what they will be, because legislation may change from moment to moment. Under these conditions, many of our friends have said to themselves : we cannot see how a formula can allow for this. Now in the particulars given by

an Austrian company, I have found the words " contract working ". That is to say, that any given concessionary, taking a lease for a line from a department — which is what we have to consider in France — or from the State, should no longer undertake the operation except under conditions of repayment of expenses, for instance, with an economy premium of one kind or another. That is what is meant, generally speaking, by such contract working. I am not able to give a hard and fast definition of contract working, because I know of no case where it has been applied with us. When such an application is proposed, it will evidently be necessary to discuss it thoroughly.

I have mentioned the expenses which it is impossible to know. Thus the Austrian North Western stated : " There are so many risks which the operator runs, that no formula can be accepted on another basis than that of payment of his costs for working." That is what is meant. Then it was said it would be necessary to adopt a system of contract working in which for instance the expenses would be repaid, but there would be an economy premium, of one kind or other. In such cases, the operator must be interested to reduce his expenses as much as possible, so that this must not be an amount which cannot be disputed. But this, I repeat, is only a general statement.

Mr. von Ziffer. (In German.) — In Austria, two systems exist. Under the first, which is, however, only applied in very few cases, the administration of the State undertakes the operation and by virtue of this has the right to a certain percentage of the gross receipts. But as a general rule the State undertakes the operation of local lines subject to the repayment of the net cost. If the cost of construction is not covered, the concession or contract states in certain cases that the deficit of the working expenses shall be repaid in time. In other words, the deficit is advanced by the State subject to 4 per cent interest. In this way, railways which cannot, as far as can be foreseen, meet their working expenses, are nevertheless able to acquire a concession of this kind, for those who supply the funds, that is to say the shareholders, are sure of a return of 4 or 5 per cent.

In Hungary, matters are different. I add this because one always says Austria-Hungary. In Hungary, the operation undertaken by the administration of the State Railway, is charged to the company at 50 per cent of the gross receipts; the standard form of contract stipulates for this 50 per cent of the gross receipts. The difference the Hungarian State has to look after, so that every railway concessionary knows that 50 per cent of the gross receipts, whether high or low, are available for the shareholders.

Mr. Machowetz. (In German.) — In order to supplement the information given by our vice-president, Mr. von Ziffer, I may mention that we also use a working formula in which a fixed sum is provided, for instance 4,000 kronen per kilometre (£267 per mile), from which the expenses have to be taken.

Mr. von Ziffer. (In German.) — Those cases are, however, very rare; as a rule the line is taken over subject to the repayment of the establishment charges.

Mr. Machowetz. (In German.) — But that wording of the conclusion is of little practical importance. If the local railway is constructed under good conditions from the financial point of view, it will not consent that the other party concerned should share in the profit. This way of working can only apply to mediocre lines and the operator will as a rule not agree to such a condition.

Mr. von Ziffer. (In German.) — I think that the leasing of the working is considered here. If that system of working yields any particular profit, the one who has made the leasing contract should also benefit by it.

Let us assume that the State leases the operation of a line; then, starting from a certain yield, the owner of the railway must also profit by it. That is what one wishes to express and I think that that is quire correct.

Mr. Machowetz. (In German.) — I only wish to speak about particular railways, that is, about those of which one operates the other : there hardly will be an agreement of this kind.

Mr. von Ziffer. (In German.) — I am in a general way in favour of operation by leasing. I frankly assert this and it is much to be regretted that leasing does not become the rule. No doubt there are exceptions. But this system of operation is the only correct one, for then both parties are interested.

Mr. Machowetz. (In German.) — But as experience shows, it is difficult to apply it in practice.

Mr. de Burlet. (In French.) — I congratulate myself on having asked Mr. Plocq for explanations.

I perfectly understood what is meant by contract working. I am still all the more satisfied that I brought out these explanations, because they have elucidated the discussion and cleared away every misunderstanding. As for me, I cannot agree to a conclusion which would recommend a system in which the operator would be repaid his working expenses in accordance with the expenditure accounts which he would produce. That is to incur serious trouble and great difficulties, to expose oneself to continual disputes. Accordingly in some countries a contract is made ; the operator is told : we will pay a fixed sum per kilometre for working expenses. I understand this system up to a certain point, without, however, considering that it is to be recommended ; but at all events it prevents innumerable disputes. It is quite a different matter to have to dispute the accounts for the working expenses, submitted by the operator.

All those who have to do with the operation of railways know that there is nothing more difficult than to draw up working accounts which are not open to dispute. There are elements which vary from one case to another : amortization, general expenses, repairs, insurances, etc. An operator can, if it is to his interest, try to swell his accounts, and that would nearly always be the case with the system mentioned. There is a certain elasticity in determining the working expenses and the operator will not fail to try to take advantage of this.

Mr. Plocq, *reporter.* (In French.) — I do not recommend this system.

Mr. de Burlet. (In French.) — You, however, seem to do so.

Mr. Plocq. (In French.) — Then I have expressed myself badly.

Mr. de Burlet. (In French.) — You say : " We are not far from thinking that *the solution to be preferred is that of contract working* as described by an Austrian company."

Mr. Plocq. (In French.) — I ask for permission to explain. I said this : one seeks concessionaries in France (one must speak a little about one's own country), one finds them with difficulty because they fear to be face to face with continually-growing expenses not allowed for in their contracts. Under these conditions, the Austrian Company says, after trial : " No agreements will be made except on the basis of payment of the cost of working."

Hence I ask, if that is not so, is it not possible to find a formula which would interest the operator? But as for proposing this as a conclusion, no! It is a suggestion, that is all.

Mr. de Burlet. (In French.) — Then we are in agreement. We will resume this discussion the day when a formula has been discovered for this contract working, that is to say the blue bird which one is about to seek. (*Laughter.*)

The President. (In French.) — If nobody else wishes to speak, we will now consider the drafting of the conclusions to be submitted to the general meeting.

Mr. de Burlet. (In French.) — This is the wording proposed by Mr. Plocq :

" The Congress, having considered the developments of the different systems applied, notes more especially the favourable results obtained by the Belgian system (establishment of a national suburban railway company), and thinks that it is impossible to recommend a general formula applying indiscriminately to all countries, in which legislation, customs, needs and economical conditions all vary. Everybody recognizes that in cases of leasing..."

I have taken the liberty to add, at Mr. von Ziffer's request : " *a system which it appears is to be recommended.*"

Mr. Plocq then continues : " It is necessary to find a formula enabling the operator to remunerate the capital he has engaged, but it is not necessary that this formula should be the same every where. Everybody can find in the documents submitted to the Congress " and we might add, in the discussions, " elements of a solution suitable for each country and for each individual case." I propose to add : " It, moreover, seems desirable that the question should remain among the agenda." I think, in fact, that the subject cannot be considered as exhausted.

Mr. Campiglio proposes the addition : " It is advisable that the working conditions should allow for, and be drawn up with a view to, inducing the operator to serve the public well, to develop the traffic and to increase the number of trains as necessary."

Mr. C. Sapin, Côtes-du-Nord Railway, France. (In French.) — Mr. de Burlet, with his usual lucidity, explained to us this morning the system adopted by the Belgian National Suburban Railway Com-

pany. The decision we are going to take contains an allusion to the organization of this company. Now, a little further on, there is a question of leasing. This morning, however, it was said that the lessees of the Belgian suburban lines did not supply any capital. Then what has the phrase : " enabling the operator to remunerate the capital he has engaged " to do in the resolution? There is an ambiguity there.

In France, there has unfortunately been brought forward a bill which thoroughly commits us to a very dangerous course, absolutely opposed to the system adopted by the Belgian National Suburban Railway Company; it is a question of the obligation of the concessionaries to supply a certain part of the original construction capital. Up till now that did not appear in the law, but only among precedents.

We have three different systems : we have one set of railways to which we did not supply capital; another to which we supplied 10 per cent; and a third to which we supplied 50 per cent.

Now these all give the same working profits per kilometre. Consequently, that in which we have no capital is wonderful from the point of view of yield, while that in which we supplied 50 per cent is very so-so as regards yield.

Let us state whether we praise the system of the Belgian National Suburban Railway Company, or whether we do the contrary.

The departmental administrations generally give 4 per cent for the capital supplied and they lend at 3·5 per cent; consequently they do bad business.

If we supplied capital to the extent of 15,000 or 20,000 francs per kilometre (£965 or £1,285 per mile), we should certainly be in a worse position if we had no capital engaged.

I ask therefore, yes or no, whether we vote for the Belgian system.

Mr. de Burlet. (In French.) — There is a mistake involved in that. We have not to vote for the Belgian system; that would be contrary to the traditions of the Congress.

This is the conclusion :

" The Congress, having considered the developments of the different systems applied, notes more especially the favourable results obtained by the Belgian system (establishment of a national suburban railway company)..." and then we add : " and thinks that it is impossible to recommend a general formula..."

Mr. C. Sapin. (In French.) — Go on, you will get to the leasing.

Mr. de Burlet. (In French.) — "... applying indiscriminately to all countries, in which legislation, customs, needs and economical conditions all vary. Everybody recognizes that in cases of leasing, a system which it appears is to be recommended, it is necessary to find a formula enabling the operator to remunerate the capital he has engaged, but it is not necessary that this formula should be the same everywhere..."

Mr. C. Sapin. (In French.) — There you are!

Mr. Philippe, Belgian Northern Railway. (In French.) — The operators of the Belgian Suburban railways are not bound to supply any of the original construction capital,

but a capital which is to serve as security for the National Suburban Railway Company, plus the funds necessary for building the repairing workshops, the furniture, the tools, the stores and finally the working capital.

Accordingly, it cannot be asserted that they have no capital. The capitals are reduced, it is true, but they still are of considerable importance, amounting to about 5,000 francs per kilometre (£320 per mile).

Mr. de Burlet. (In French.) — Then there is no contradiction. I was just about to make this remark.

Mr. Lembourg, National Suburban Railway Company, Belgium. (In French.) — Mr. Sapin aims at the phrase in which leasing is recommended. He finds that that phrase does not properly harmonize with the rest of the proposed conclusion.

Mr. Plocq. (In French.) — The phrase aimed at by the honourable member runs as follows : " Everybody recognizes that in cases of leasing, a system which it appears is to be recommended, it is necessary to find a formula enabling the operator to remunerate the capital he has engaged."

I proposed this wording because I thought that this could apply to all the States and all the methods of procedure.

Among the information supplied to us, we see many different methods of procedure, from Germany where there is a growing tendency for the provinces to build the lines and for private parties to operate them, to Hungary, where on the contrary private parties build the lines and the State operates them.

It follows that the formula giving the operator the means to remunerate the capital engaged by him can apply, in my opinion, to all formulæ and to all countries.

That phrase cannot offend anybody. Moreover, our conclusions should be drafted in such a way as not to inconvenience anybody. We are bound to obey the laws of our country. We have no power to give lessons to our legislators.

The President. (In French.) — We could strike out those words which might be misinterpreted.

Mr. Plocq. (In French.) — That is what I was going to ask.

Mr. de Burlet. (In French.) — We are in agreement. This then is the conclusion which we propose to you to present to the general meeting :

" The Congress, having considered the developments of the different systems applied, notes more especially the favourable results obtained by the Belgian system (establishment of a national suburban railway company), and thinks that it is impossible to recommend a general formula applying indiscriminately to all countries, in which legislation, customs, needs and economical conditions all vary.

" Everybody recognizes that the formula required should enable the operator to cover his expenses, including the remuneration of the capital he has invested ; that formula cannot be the same everywhere : everyone can draw, from the documents laid before the Congress and the discussions, the elements of the solution to be adopted in each country in each case.

" It is advisable that the working condi-

tions should allow for, and be drawn up with a view to, inducing the operator to serve the public well, to develop the traffic and to increase the number of trains as necessary.

" It is to be desired, as the subject has not been exhausted, to retain it on the agenda of the next Congress."

The President. (In French.) — If there is no opposition, I declare this wording adopted.

DISCUSSION AT THE GENERAL MEETING

Meeting held on 14 July, 1910 (afternoon).

MR. P. WEISSENBACH, PRESIDENT, IN THE CHAIR.
GENERAL SECRETARY : MR. L. WEISSENBRUCH.
FIRST ASSISTANT GENERAL SECRETARY : MR. MÜRSET.
SECOND ASSISTANT GENERAL SECRETARY : DR. A. BONZON.

Mr. de Burlet, *vice-president of the 5th section*, read

Report of the 5th section.

(See *Journal de la huitième session*, No. 6, p. 10.)

" Mr. PLOCQ, the reporter, set forth, in their main features, the laws in force affecting light railways in the different countries; he mentioned the different systems adopted by the public authorities (States, departments or provinces, communes) for giving pecuniary support to the construction or operation of these railways, and described the results obtained.

" He concluded that it was hardly possible to find any system of working capable of being uniformly applied in all cases which might occur; he mentioned that one Austrian company praised the principle of State operation.

" MR. CAMPIGLIO (*Italian local railway Union*) gave certain details of the new Italian legislation, which increased the size of the subventions granted by the government under the provisions of the former law, but on the other hand, materially increased the share the State received when the gross receipts exceeded a certain limit. According to Mr. Campiglio, this clause would prove an obstacle to the growth of the traffic, as it might be to the interest of concessionary companies not to attain this limit.

" MR. MACHOWETZ (*Austrian State Railway*) gave the meeting some figures referring to the traffic on the secondary Austrian lines in the year 1908. Mr. VON ZIFFER (*Lemberg-Czernowitz-Jassy Railway, Austria*) stated that a new law was being worked out on the subject of secondary railways and noted that this proposed law was sub-

jected to sundry criticisms by the companies concerned with such lines.

" Several delegates, including Messrs. Pedro Suarez (*Bolivian government*), Bello (*Portuguese National Railway Company*), de Souza (*Portuguese State Railway*), Waechter (*Vering and Waechter Company, Germany*), Donker Duyvis (*Semarang-Cheribon line, Dutch Indies*), Girtanner (*Swiss government*), Forrest (*Madras & Southern Mahratta Railway*), gave some interesting details about the development of secondary lines in their respective countries and the results obtained with them.

" Mr. de Burlet (*Belgian National Suburban Railway Company*) explained the legal organization of his company, which was really a public administration operated with the help of capital, half of which was usually subscribed by the State, and half by the provinces and communes interested. The different lines were leased either to local private companies, or, in certain cases, to special companies formed by the communes interested. In the case of one group of lines, this was leased to the company owning the main lines to which these lines served as feeders.

" Mr. de Burlet gave some interesting figures about the development and the traffic of the Belgian National Suburban Railway system.

" He found that the system of State operation referred to by Mr. Plocq at the end of his report, was difficult to apply and might give rise to abuses and to disputes.

" Mr. Plocq recognized that there was truth in this criticism, but objected that taking into consideration the continually growing expenses which operators (both of main lines and of secondary lines) had to incur, more especially in consequence of the different social laws passed in many countries, it was no longer possible to make working contracts which did not expose the operators to serious losses. This uncertainty was calculated to discourage private enterprises from undertaking the operation of secondary lines.

" After several remarks on this point, more especially by Mr. C. Sapin (*Côtes-du-Nord Railway, France*), the section agreed to submit the following conclusions to the general meeting."

The President. — The following are the

CONCLUSIONS.

" The Congress, having considered the
" developments of the different systems
" applied, notes more especially the
" favourable results obtained by the
" Belgian system (establishment of a na-
" tional suburban railway company), and
" thinks that it is impossible to recom-
" mend a general formula applying indis-
" criminately to all countries, in which
" legislation, customs, needs and econ-
" omical conditions all vary.

" Everybody recognizes that the formula
" required should enable the operator to
" cover his expenses, including the
" remuneration of the capital he has in-
" vested; that formula cannot be the same
" everywhere : everyone can draw, from
" the documents laid before the Congress
" and the discussions, the elements of the
" solution to be adopted in each country
" in each case.

" It is advisable that the working condi-
" tions should allow for, and be drawn
" up with a view to, inducing the operator
" to serve the public well, to develop the
" traffic and to increase the number of
" trains as necessary.

" It is to be desired, as the subject has
" not been exhausted, to retain it on the
" agenda of the next Congress."

— These conclusions were confirmed by the general meeting.

SECTION V : LIGHT RAILWAYS

[625 .616 & 625 .617] QUESTION XIX

LOCOMOTIVES AND ROLLING STOCK

OF

NARROW-GAUGE LIGHT RAILWAYS

A. — *Types of the latest locomotives used on narrow-gauge light railways, with due consideration to the profile of the line and the class of traffic.*

Is it advisable : 1° to protect the wheels and the moving parts by a metal cover ; 2° to have a foot-plate at each end of the locomotive? What regulations are there on the subject?

B. — *What are the latest types of carriages and wagons used on narrow-gauge light railways?*

Reporter :

All countries — Mr. Moriz Jessen, engineer, inspector, Austrian Southern Railway.

REPORT

By Moriz JESSER,

ENGINEER, INSPECTOR, AUSTRIAN SOUTHERN RAILWAY.

SUMMARY.

Introduction.

Section I. — *Question A. — Latest types of the locomotives :*

1. General considerations.

2. Noteworthy types of locomotives.

A) Railways with a gauge of 610 millimetres (2 feet).
B) Railways with a gauge of 750 millimetres (2 ft. 5 1/2 in.).
C) Railways with a gauge of 760 or 762 millimetres (2 ft. 5 15/16 in. or 2 ft. 6 in.).
D) Railways with a gauge of 785 millimetres (2 ft. 6 29/32 in.).
E) Railways with a gauge of 890 or 891 millimetres (2 ft. 11 3/64 in. or 2 ft. 11 3/32 in.).
F) Railways with a gauge of 914 millimetres (3 feet).
G) Railways with a gauge of 950 millimetres (3 ft. 1 3/8 in.).
H) Railways with a gauge of 1,000 millimetres (3 ft. 3 3/8 in.).
I) Railways with a gauge of 1,067 millimetres (3 ft. 6 in.).

3. Chief properties of the locomotives :

A) Horse-power.
B) Adhesive weight.

4. General conclusions :

A) As regards track.
B) As regards locomotives.

Section II. — *First supplementary question. Protection of the moving parts :*

1. General considerations.
2. The use of covers.
3. Results obtained in practice.
4. Summary.
5. Conclusions.

*

Section III. — *Second supplementary question : Arrangement of two footplates :*

1. General considerations.
2. Description of the designs :
   A) With passage way round the locomotive.
   B) Raised cab.
   C) Two drivers cabs.
   D) Driver's cab on the carriages.

Conclusions.

Section I. — A) Tracks.
B) Locomotives.

Section II. — Protection of the moving parts.

Section III. — Arrangement of two footplates.

Appendix I. — Latest types of locomotives :

1. Detailed list of questions.
2. List of the administrations who sent answers.
3. Summary of the tables of the types of locomotives.
4. Particulars of noteworthy types.

Appendix II. — Protection of the moving parts :

1. Detailed list of questions.
2. List of the administrations who answered.
3. Reports of the administrations.

Appendix III. — Two platforms :

1. Detailed list of questions.
2. List of the administrations who sent answers.
3. Reports of the administrations.

INTRODUCTION.

Subject XIX, which is to be discussed at the eighth session of the Railway Congress, may be divided, as far as littera *A* (locomotives) is concerned, into three sections, which are entirely independent of each other. These are :

1° The principal questions, namely the most recent types of locomotives, together with two supplementary questions, namely:

2° The advisability of protecting the moving parts, and

3° The advisability of having two footplates.

In accordance with this subdivision of the subject, the report itself as well as the appendices are divided into the corresponding three sections. Each appendix contains, in the first place, the list of questions, secondly, the list of the railway administrations who have supplied information on the subject, and thirdly and fourthly, the particulars and answers themselves, which, according to their importance, are either reproduced in full or only in the form of extracts. It was not possible, both in the interests of conciseness and on account of the limited space available, to reproduce all the numerous sketches and drawings which were received, and it was necessary to limit oneself to a selection of them.

Altogether, one hundred and twenty-six administrations have answered the list of questions, of whom forty-one have sent very complete information about the types of locomotives they have in use, and have given, in more or less detail, their views on the subject and the reasons for these views.

In consequence of the great amount of information available, the investigation of the different types of locomotives has become so voluminous, that is was not possible, within the limits of time and space available, to deal with littera *B* concerning carriages and wagons used on narrow-gauge railways, with the thoroughness the importance of the subject demands; it was therefore considered advisable to limit the report which follows, to littera *A*, in order to be able to complete this part of the subject; and it is left to the Congress to discuss the littera *B* later on.

SECTION I.

QUESTION *A*.

Latest types of the locomotives used on narrow-gauge railways, with due consideration to the profile and the class of traffic of the lines.

I. — General considerations.

Particulars sent by forty administrations are available for the consideration of this subject. These include one hundred and seven types of locomotives for eleven different gauges, nine of which differ materially from each other, while two, owing to the

small differences of 1 and 2 millimetres ($^3/_{64}$ and $^5/_{64}$ inch) respectively, will not be considered separately. The chief particulars of ninety-four of these types are given in the third part of appendix I, while the most important types are described in detail in the fourth part of appendix I, diagrams of the axle-arrangement being given; thirteen types, which only differ from others of the same railway administration, are not specially described, but only noted. The classification, according to gauge, of the different administrations and types, and the corresponding number of locomotives, are given in the following table:

Gauge, in millimetres.	Number of Administrations.	Types.	Locomotives.
A) 610	2	2	8
B) 750	4	6	172
C) 760 / 762	9	24	195
D) 785	1	4	55
E) 890 / 891	2	10	104
F) 914	4	17	36
G) 950	1	1	12
H) 1,000	17	31	176 + 561 (1)
J) 1,067	4	12	54
Number 11.	44 (2)	107	1,373
or 9.	or 40	On the average, 12·8 locomotives per type.	

(1) As regards 561 locomotives of the Belgian National Suburban Railway Company, which are of two very similar types of the C class, it is not stated how many of each run on each of the two gauges used (1,000 and 1,067 millimetres); consequently the total applies to the two gauges jointly.
(2) Four administrations use two gauges.

Thus on the average, there are about 12·8 locomotives per type, and if we exclude the 561 locomotives of two types which all belong to one large undertaking, we only have 812 locomotives to 105 types, or on the average only 7·7 locomotives per type.

Now although individual details of a few of the types enumerated may be interchangeable, it cannot be overlooked that the very small average number of locomotives, built to one set of drawings and patterns and templets, and requiring other special appliances and tools, must have an unfavourable influence not only on the prime cost of the locomotives, but also on their cost of maintenance.

When making a retrospect over the creative work of some tens of years in connection with a special subject, it is undoubtedly justifiable to consider measures which seem suitable to avoid or reduce disadvantages which have resulted from too great individualization when the lines were designed. In this way, it is probable that a very injurious in-

fluence was exercised by the creation of such a large number of gauges, which in some cases only differ by from 10 to 23 millimetres ($^{13}/_{32}$ to $^{29}/_{32}$ inch), and some of which could have been eliminated at a very trifling expense.

This subject is however at present outside our scope, and we have to deal with the gauges as they exist. But the existing conditions lead to the conclusion that it is advisable, when selecting locomotive types for a new line or when ordering locomotives for an existing line, to pay attention, when considering prices, to the above considerations, and to try to limit the excessive growth in the number of different patterns. It can not be overlooked, in this connection, that some administrations have been swayed by considerations of the kind, for in some cases they have given repeat orders for locomotives of the original type after eleven, thirteen and even fifteen years.

In our case, it seemed advisable to classify the different locomotives in the first place according to gauge, in order to make comparison possible and to facilitate it, and only consider the official classification of the administrations concerned as secondary. The classification made on this basis is given in the second part of appendix I.

A first glance at the rather extensive array of figures shows that in spite of its extent it does not offer a general view of all the locomotives of those administrations who have sent answers to the list of questions, but that many of the administrations have limited themselves strictly to the wording of the question, and have only given particulars of the types of the latest locomotives, while others have given a more or less complete account of their whole locomotive stock. Now although it is self-evident that no comprehensive statistics can be drawn up on such a basis, which would no doubt be of great value for the study of the subject, yet nearly all types were included in the third part of appendix I. The point of view taken was that the progress made in those types, which have become worked out by the better utilization both of the materials used in construction as well as of the materials consumed and as a result of the experience gained, can be better gauged by a comparison with the original designs, than if the new designs alone are considered.

Before we begin the consideration of the individual types, we will make a few remarks on the points of view from which we can examine the cumbrous and apparently intractable mass of figures and data. The most important properties, which interest us in connection with a locomotive and especially a narrow-gauge locomotive, running on a line with a difficult profile and plan, include the possibility of smooth running round curves at a proper speed, and a tractive force or power suited to the needs of the traffic, without exceeding the maximum axle-loads admissible with a light road and road-bed.

The following table of the limits of the minimum radii of curves and of the maximum gradients (classified according to gauge) on the different lines this report deals with shows the magnitude of the demands made in some cases on the locomotives, as regards the curves and gradients on the line.

Gauge, in millimetres.	Minimum radius of curves, in metres.		Maximum gradient, per mil.	
	Greatest.	Smallest.	Steepest.	Most gentle.
A) 610	100	61	30	16·6
B) 750	106·7/64	40/30	40	15
C) 760/2.	152·4	50	32·4	6·6
D) 785	...	40/35	40	...
E) 890/1.	300	148/119	27·6	16
F) 914	70	47	82·5	25·6
G) 950	...	100	25·0	...
H) 1,000	450	21	58·82	0
J) 1,067	322	25	70·0	6·6

Remarks. - The smallest radii of curves at switches are given as the denominators of the numerators which give the figures for the open line.

On the other hand, this table shows that the conditions on some of the narrow-gauge lines are more favourable than on some standard-gauge lines.

Now as regards the kernel of the question, the power of the locomotives, the information given by a few of the administrations only do not render it possible to make any proper comparison between the locomotives of different railways; nor was this to be expected, because many special conditions affect the direct comparison both of the train-loads hauled, and of the horse-power actually produced, too much to make it possible to use them for purposes of direct comparison. When we consider the train weight on a given gradient, and the speed there obtained, there are so many disturbing influences at work that no comparison can be made. Such are :

The possibility of overworking the boiler on short up-gradients by allowing the water-level to become temporarily lowered, and feeding it up again while on the next more favourable section; or the possibility of favourable distribution of the speed over smaller sections having different gradients. These varying conditions form an obstacle to the determination of the actual power produced, from the figures given. A further source of error arises from the use of fuel of different origins, or even of different qualities when obtained from one and the same coal pit, even if its calorific value or evaporative power is correctly given, for even these figures are liable to vary within wide limits. In addition to these disturbing factors, we must also mention the varying intensity of the fire, the difference in the skill of the locomotive crews, and many other influences which can not be calculated. Similar errors occur in the

comparison of the statements as regards the horse-power produced at different places and under different conditions, although these figures may be perfectly correct under the individual conditions concerned.

Even a practised eye will find it impossible, at first glance, to make any comparison of the different types on a uniform basis, as so many factors are involved, such as heating surface and its distribution, working pressure, superheating, compounding, quality of the fuel, briskness of the fire, etc. In order to make such a comparison possible, it is necessary to determine quality coefficients for a definite kind of fuel and a standard working pressure in the boiler, from its dimensions and other particulars as given above; the quality coefficients would naturally only apply under the particular conditions assumed and might be materially higher or lower under other conditions.

In the case of the large boilers of standard-gauge locomotives, it is usual to take as basis the evaporative power or the output per unit of the fuel used; but this is not advisable in the case of narrow-gauge locomotives, for we must allow for the less favourable conditions of the combustion of coal on small grates, especially if the coal contains much ash or, still worse, forms clinker; also for the smaller length of the smoke tubes, which results in a less economical utilization of the heat generated by the combustion, and finally for many other similar losses which, as experience shows, forms a greater proportion of the whole than in the case of large units of traffic.

In order to obtain useful coefficients for this particular purpose, the administration of the Austrian Southern Railway carried out a number of coal tests on some of its narrow-gauge lines, where there are sections with long gradients which are fairly uniform. Different kinds of coal, chiefly of better quality, were used, and all the measurements and observations were taken as carefully as possible in order to obtain a correct representation of the conditions there obtaining. The output of power was calculated from the train weights and the gradients, and the following results were obtained, besides others of great value to the locomotive engineers of narrow-gauge lines, but which do not fall within the scope of the present report :

Small locomotives, with a grate area which does not differ by much from 1 square metre (10·76 square feet), using saturated steam and working with twin cylinders, give, when good Cardiff coal is used, and the draft is as brisk as possible, as is most advantageous to a long life of the fire-box and of the tubes, a continuous output in horse-power (L) equal to the working pressure in metric atmospheres (p) multiplied by the sum of the fire-box heating surface (B) plus quarter the smoke-tube heating surface in square metres (R); *i. e.* :

$$L = p\left(B + \frac{R}{4}\right).$$

This empirical formula can make no claim to mathematical accuracy such as is attempted in calculating purely-mechanical relations; for, taking one item only, the power does not vary directly as the working pressure. Yet the formula can be used for determining the power of

locomotives within the limits indicated, under the conditions here assumed, sufficiently approximately for practical purposes.

In the case of locomotives using superheated steam, and with compound working, the power estimated as shown above will require to be increased. Each of these two improvements makes it possible, under favourable conditions, to obtain up to 20 per cent more power out of the steam produced. It must however not be overlooked that locomotives, when on the steepest gradients, have as a rule to give materially more power than would correspond to the best utilization of the steam produced or of the coal burnt; for in addition to this, there is also the cost of the locomotive crews, which has a much more unfavourable influence of the cost per unit of power of the locomotive when the output of power is small, than a somewhat greather consumption of coal and a correspondingly-greater fatigue of the boiler and engine. In order to obtain the lowest total expenditure on tractive power per ton-kilometre, the locomotive must therefore do more work than if the object aimed at was the best utilization of the fuel. These reasons make it advisable not to allow for the increase in power the maximum values determined in the experiments, but to allow in each case about 10 per cent, paying due regard to the existing traffic conditions.

The figures so obtained are given in the tables of the chief particulars in the third part of appendix I, while the fourth part, which merely reproduces the statements of the administrations, only gives the power as given by the administrations. On the whole, the two sets of figures show a rather satisfactory agreement, taking the different calorific values of the fuel used into consideration; a few greater discrepancies are no doubt due to variations in the conditions mentioned above, probably more especially to differences in the briskness of the fire.

Nevertheless, the figures given may be considered as a basis of comparison which may be used generally, for it certainly would be possible to increase the output of the locomotives which have a similar heating surface, for which lower figures are reported, by forcing the steam production, should this appear to be desirable in any individual case.

If we now pass over to the consideration of the locomotive used on the different gauges, we have to mention, besides the particulars given in the tables in the fourth part of appendix I, the following individual peculiarities.

2. — Noteworthy types of locomotives.

A. — *Railways with a gauge of 610 millimetres (2 feet)* [1].

Particulars concerning lines of this gauge are only given by two administrations of State railways in the South African colonies of Great Britain.

Rather difficult conditions exist as regards curves and gradients on these lines, such as also exist on most of the European narrow-gauge railways, having a wider gauge; the latter sometimes even show

(1) The index numbers and letters used in the text correspond with those used in the tables and descriptions given in appendix I.

worse conditions, as on the South African lines in question the minimum radius is stated to be 61 metres (3·05 chains) and the steepest gradient 30 per mil.

2) Of the two locomotive types described, that of the Natal Government Railways (fig. 1), used on the Estcourt-Weenen branch, of the most recent type, is of the 2 C 1 class, and is distinguished by having a very long wheelbase as compared with the curves run over; the total wheelbase is 5,409 millimetres (17 ft. 8 $^{15}/_{16}$ in.), while the rigid wheelbase is 1,752 millimetres (5 ft. 8 $^{31}/_{32}$ in.), and this arrangement made it possible, although carrying a considerable weight of stores, to provide a locomotive having a large heating surface (62·6 square metres [673·85 square feet]) while keeping the axle-load moderate (5·815 tons [5·723 English tons]); thus this locomotive, while working at a pressure which can not be called high, gives the high figure of 215 horse-power, *i. e.* 3·53 horse-power per centimetre (8·84 British horse-power per inch) of width of gauge and 8·13 horse-power per ton of gross weight (8·15 British horse-power per English ton).

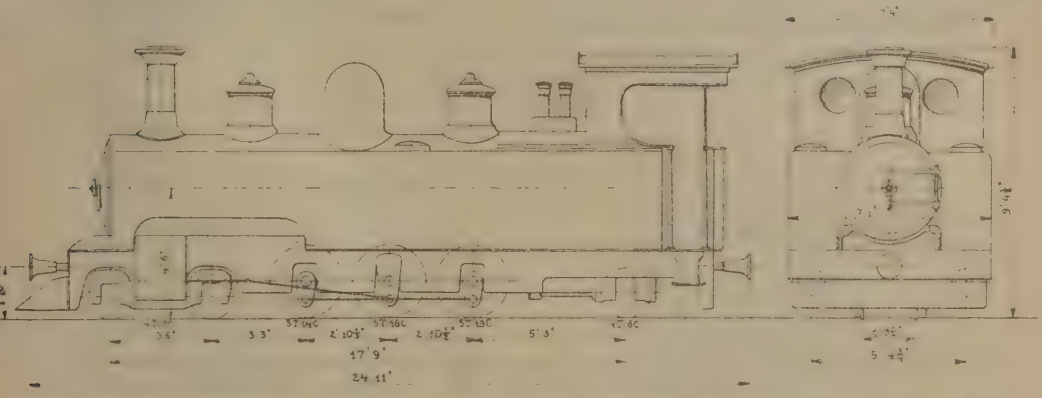

Fig. 1. — Natal Government Railways (Africa). — Tank locomotive, Stuartstown line. 610 millimetres. (Gauge 2 feet).

This locomotive is superior, both as regards its absolute power, as well as regards these ratios to gauge and weight, to the average of all the narrow-gauge locomotives. On the other hand, the adhesive weight and the maximum speed, and their relation to the power, are to be considered as moderate, as those locomotives can nearly attain the maximum speed when the former is fully utilized.

B. — *Railways with a gauge of 750 millimetres (2 ft. 5 $^1/_2$ in.)*

As regards locomotives for this gauge, particulars are sent by four administrations in Germany, Egypt and Russia.

The Saxon State Railway has a line 1) which has curves with a radius of 50 metres (2 $^1/_2$ chains) on the open line, and of 43 metres (2·15 chains) at switches, and the steepest gradient is 40 per mil. It has

had two noteworthy types of locomotives constructed.

The first, a B + B tank locomotive on the Meyer system (fig. 2), has four cylin- *a)*

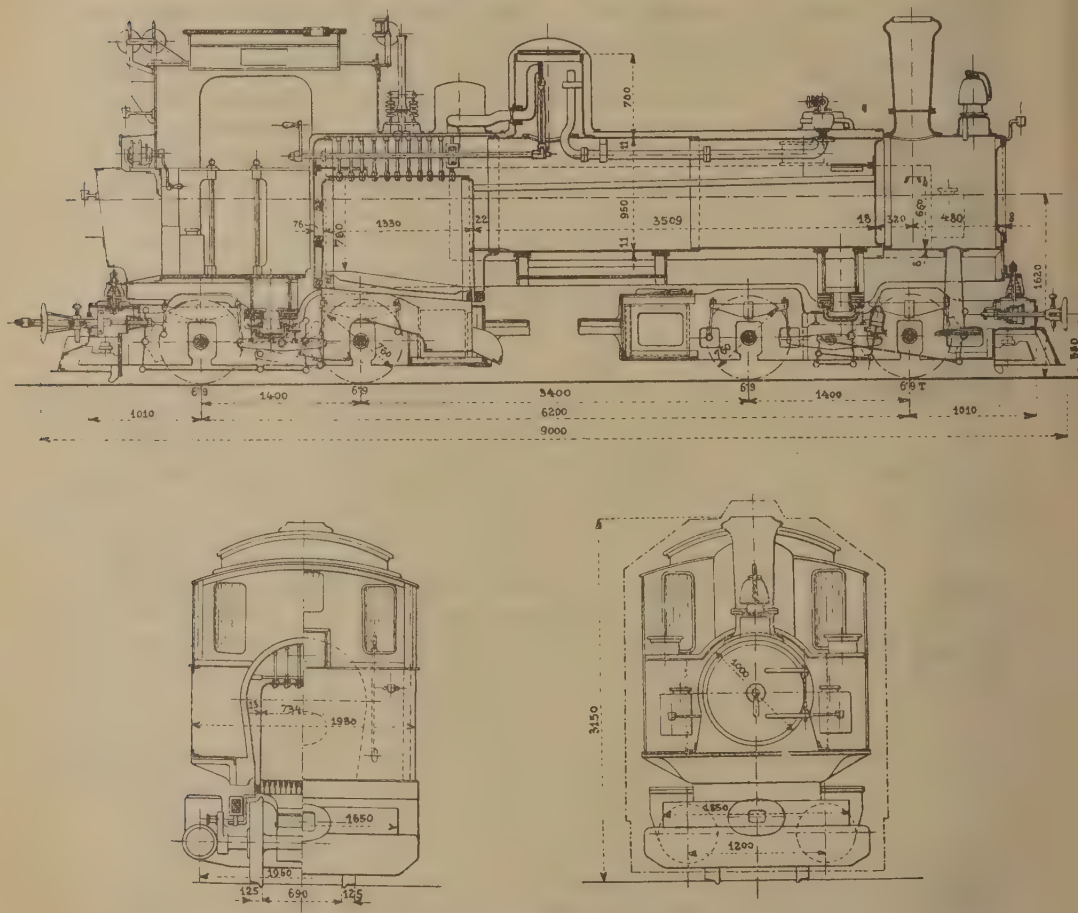

Fig. 2. — Saxon State Railway. — Four-axled narrow-gauge 750 millimetres (2 ft. 5 1/2 in.) compound tank locomotive (Meyer design).

ders and is a compound. Forty-five such locomotives were acquired during the years 1892-1908, and this proves that the administration obtained good results with this type. The whole load is carried on a large wheelbase, of 6·2 metres (20 ft. 4 in.), so that the load only amounts to 4·42 tons per metre (1·53 English tons per

foot) of wheelbase. The maximum axle-load of 6·9 tons (6·8 English tons) can not be called high; this gives the considerable adhesive weight of 27·4 tons (27 English tons). Assuming the coefficient of adhesion to be $^1/_6$ and the traction resistance to be 10 per mil, this corresponds on the steepest up gradient to an available drawbar pull of 3,200 kilograms (7,055 lb.). The other dimensions we do not materially differ from those of locomotives of similar design.

b) The second type of the same administration is a D tank locomotive (fig. 3) with a rather greater adhesive weight, and accordingly gives, assuming the same conditions as in the last case, an available drawbar pull of 3,345 kilograms (7,374 lb.) on the steepest gradient. The adoption of the Klien-Lindner system for the first and the last axle has made it possible to run over the existing sharp curves in spite of the large wheelbase of 3,900 millimetres (12 ft. 9·$^9/_{16}$ in.) of the coupled axles. In consequence of the high working pressure of 14 atmospheres and of compounding, the power abtained amounts to 250 horse-power, so that this is the most powerful locomotive of this gauge. This corresponds to 3·33 horse-power per centimetre (8·34 British horse-power per inch) of gauge and to 8·7 horse-power per ton (8·72 British horse-power per English ton) of locomotive, and thus this locomotive is superior to the average of all the types.

2) The administration of the Wurtemberg State Railway has a B + B compound locomotive on the Mallet-Rimrott system, (fig. 4) four cylinders, used on its lines, with where conditions are favourable, the steepest gradient being 25 per mil and the radii of the sharpest curves 100 and 50 metres (5 and 2 $^1/_2$ chains) respectively. This locomotive has the same adhesive weight as the previous type and gives similar power, so that what was stated in the last case also applies to this; on the gentler gradient on which this locomotive is used, the available drawbar pull will be about 3,780 kilograms (8,333 lb.).

Finally, we may mention a locomotive 4*a*) with separate tender of the *Première Société des chemins de fer secondaires en Russie*, of the D class; ninety-one of these have been acquired. As the curves which have to be run over are moderate (radii 106·7 and 64 metres (5·335 and 3 2 chains) on the open line and at switches respectively), the wheelbase could be made longer without any special arrangements, and if coal were used for firing 220 horse-power would be obtained, so that these locomotives would then come third as far as locomotives of this gauge are concerned; fired with wood, it gives 197 horse-power according to the statement of the administrations. The ratio of power to total weight, owing to the use of a separate tender, is naturally not so favourable as in other cases; it was however necessary to put up with this disadvantage, in order to be able to carry the large quantity of stores required under the existing conditions, as regards line and fuel. A similar second type is designed as a tank locomotive, and is less powerful.

C. — *Railways with a gauge of 760 or 762 millimetres (2 ft. 5 $^{15}/_{16}$ in. or 2 ft. 6 in.).*

This gauge has been adopted by a large number of administrations, so that, next

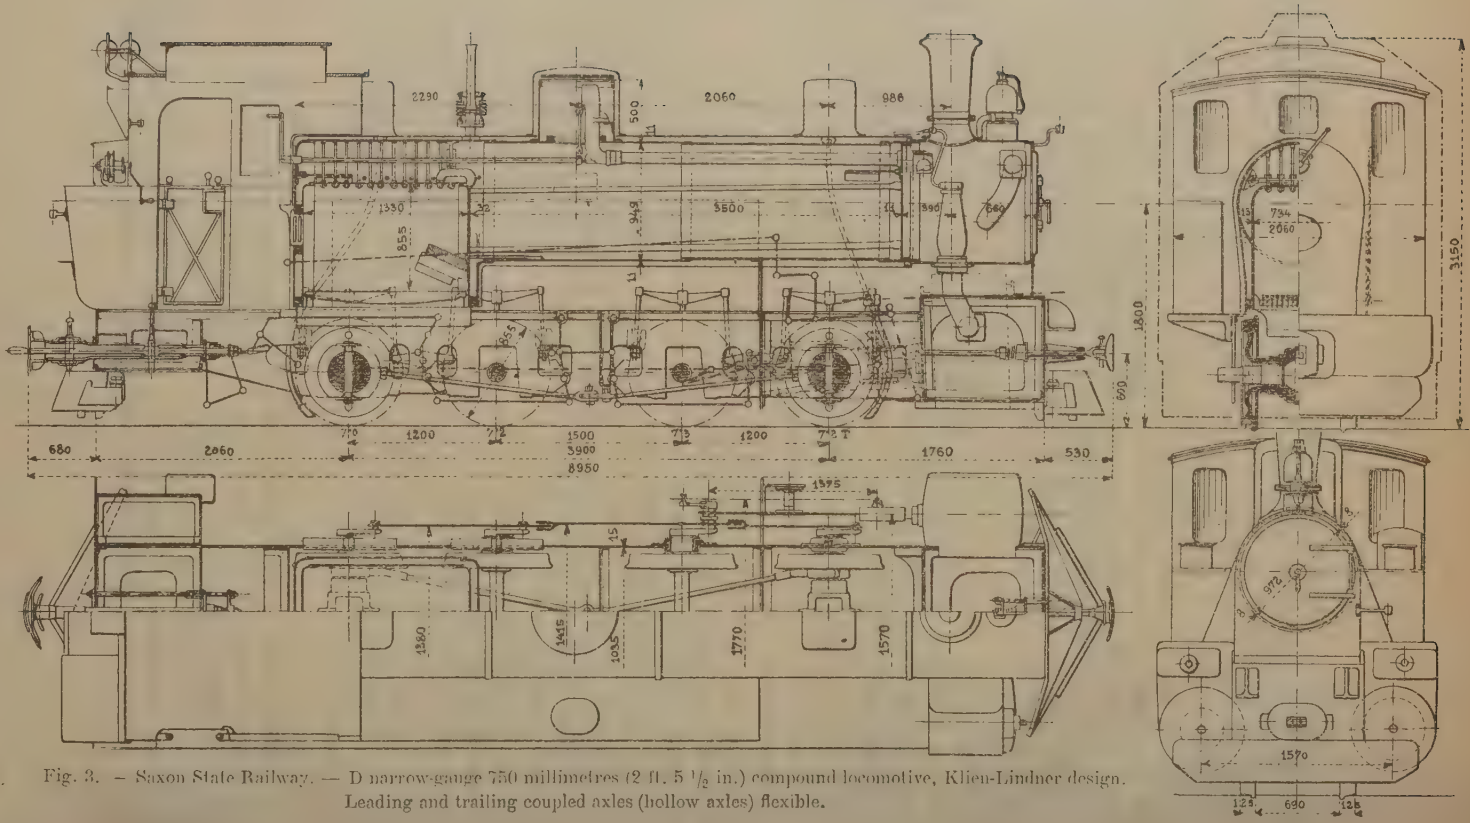

Fig. 3. — Saxon State Railway. — D narrow-gauge 750 millimetres (2 ft. 5 1/2 in.) compound locomotive, Klien-Lindner design. Leading and trailing coupled axles (hollow axles) flexible.

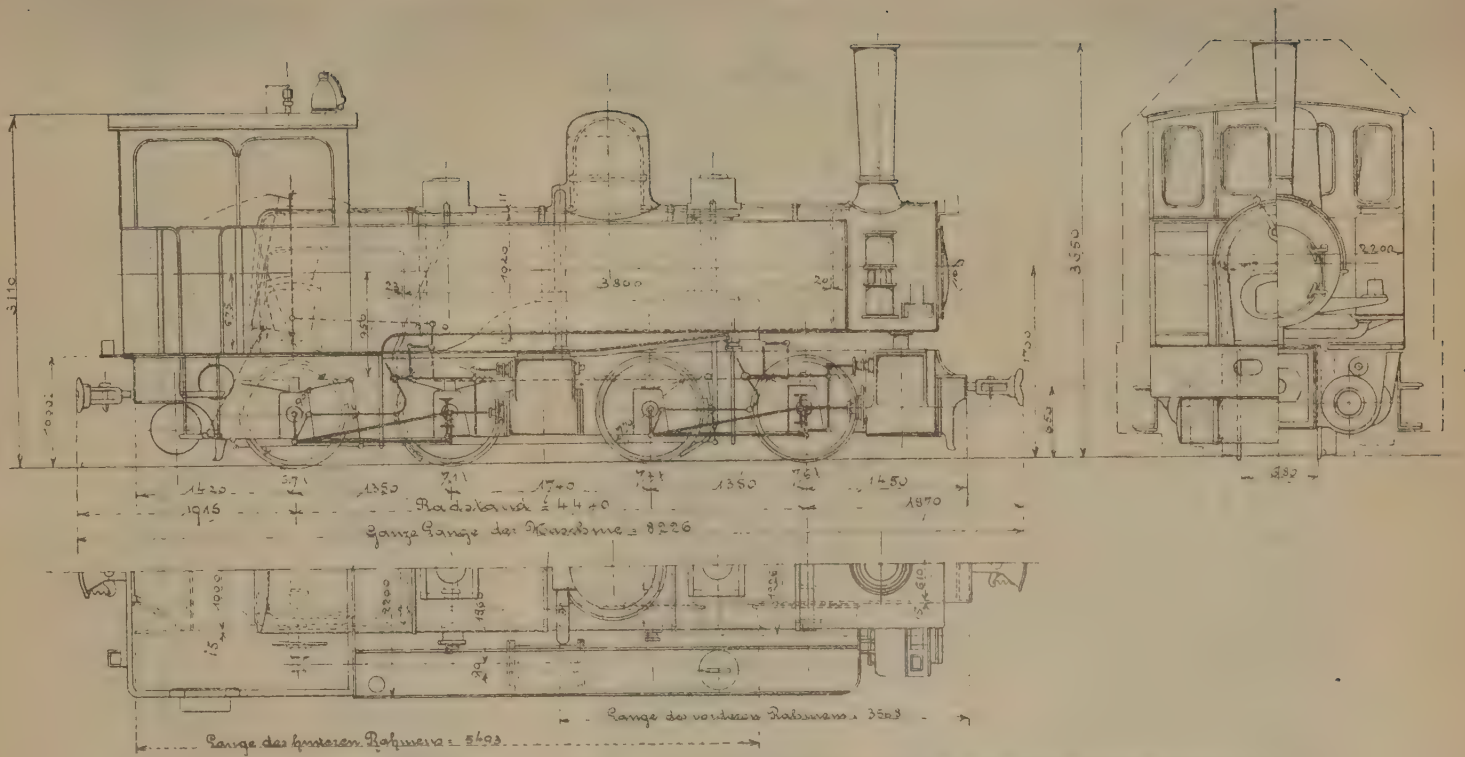

Fig. 4. — Wurtemberg State Railway. — B + B tank locomotive, type *Tssd* for narrow gauge lines 750 millimetres (2 ft. 5 ½ in.).

Explanation of German terms : Radstand = Wheelbase. — Ganze Länge der Maschine = Length over buffers. — Länge des hinteren Rahmens = Length of back frame. Länge des vorderen Rahmens = Length of front frame.

to the gauges of 1,000 and 1,067 millimetres (3 ft. 3 $^3/_8$ in. and 3 ft. 6 in.), it is most strongly represented. It is used on nine railways, and there are one hundred and ninety-five locomotives of twenty-four different types. Five of these railways are in Austria-Hungary and four are in the Empire of India.

The conditions as to curves and gradients on the lines described by the administrations in Austria-Hungary, are it is true not so very bad, but are yet rather difficult ones, as the minimum radii vary, with one conception, between 50 and 80 metres (between 2 $^1/_2$ and 4 chains), and the steepest gradients exceed 25 per mil on most lines, and even attain 32·4 per mil.

The following types are specially considered owing to some particular feature.

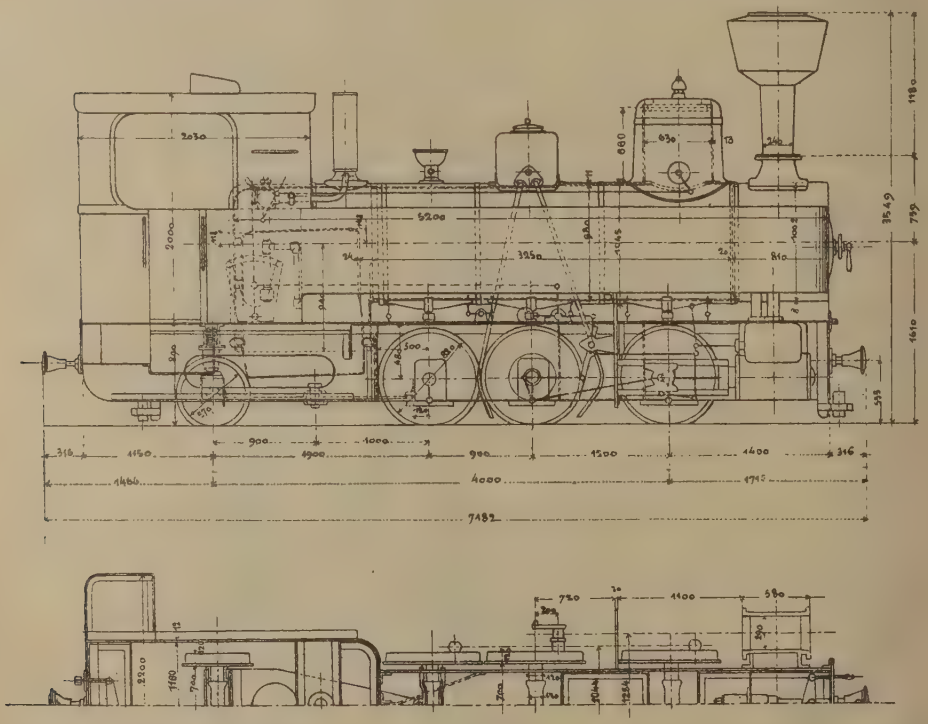

Fig. 5. — Austrian State Railway. — Narrow-gauge tank locomotive, series U, gauge 760 millimetres (2 ft. 5 $^{15}/_{16}$ in.).

1*b* and *c*) Two types (fig. 5 to 7) of the Austrian State Railway; namely a C1 tank locomotive, and a C2 tank locomotive; both have become developed by the improvement of an older weaker C1 type (fig. 5) of which fortyone were in existence. The first of these

two types (fig. 6) has an adhesive weight of 22·9 tons (22·5 English tons), and on the steepest gradient of 32 per mil, assuming the coefficient of adhesion to be $^1/_6$, the available drawbar pull is 2,660 kilograms (5,864 lb.). The second (fig. 7) has a smaller adhesive weight and accordingly gives a smaller drawbar pull. The first has axle-loads of 7·7 tons (7·6 English tons), which may be considered considerable for this gauge; its total wheelbase is 4,000 millimetres (13 ft. 1 $^1/_2$ in.) and the average load amounts to 6·8 tons per metre (2·04 English tons per foot) of track, while with the second type the load is 5·5 tons per metre (1·65 English tons per foot) of track.

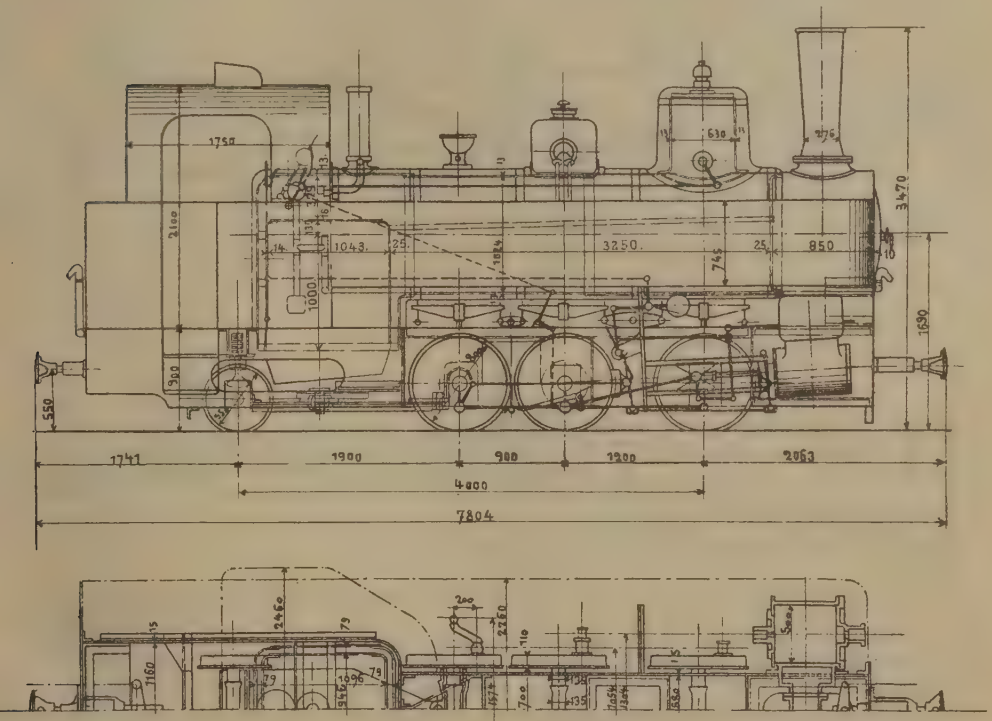

Fig. 6. — Austrian State Railway. — Narrow-gauge compound tank locomotive, series Uv, gauge 760 millimetres (2 ft. 5 $^{15}/_{16}$ in.).

The rather large wheelbase of the first type runs well round sharp curves, as the Bissel truck of the trailing carrying axle effects the corresponding lateral displacement of the last coupled axle. In the second type the two trailing carrying axles are in a bogie below the fire-box, and smooth running on the curves is facilitated by having the leading driving wheels made without flanges.

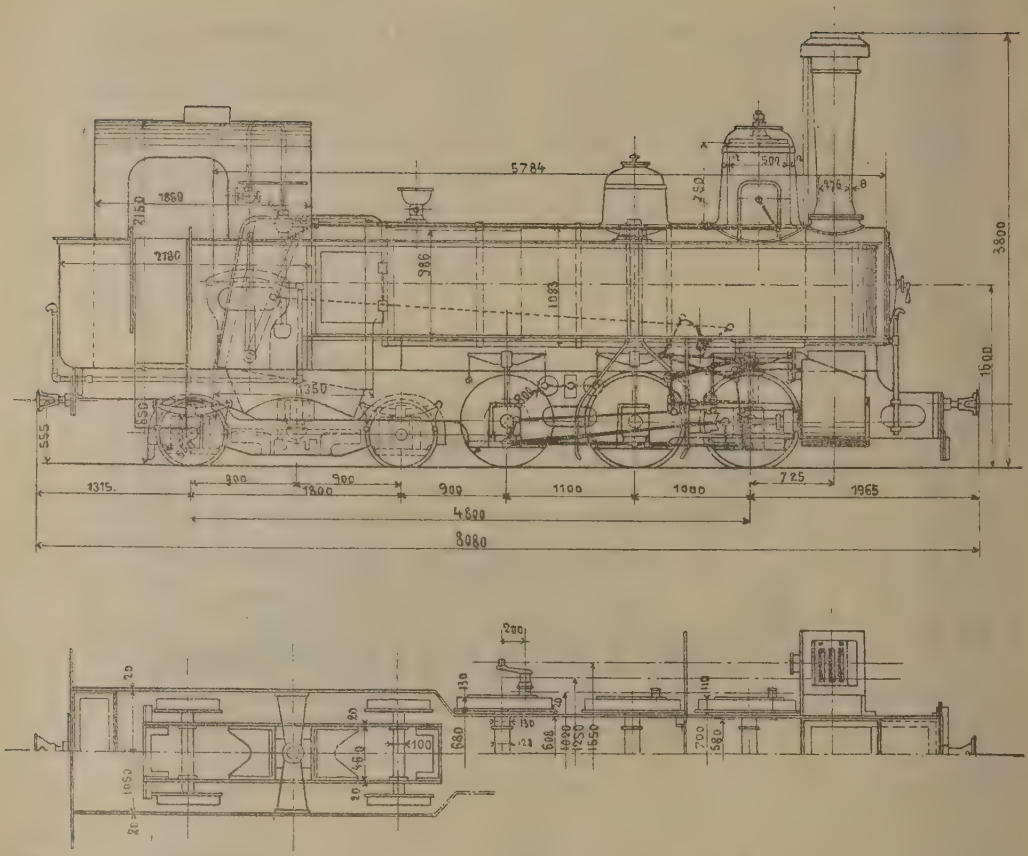

Fig. 7. — Austrian State Railway. — Compound tank locomotive, series Yv, gauge 760 millimetres (2 ft. 5 $^{15}/_{16}$ in.).

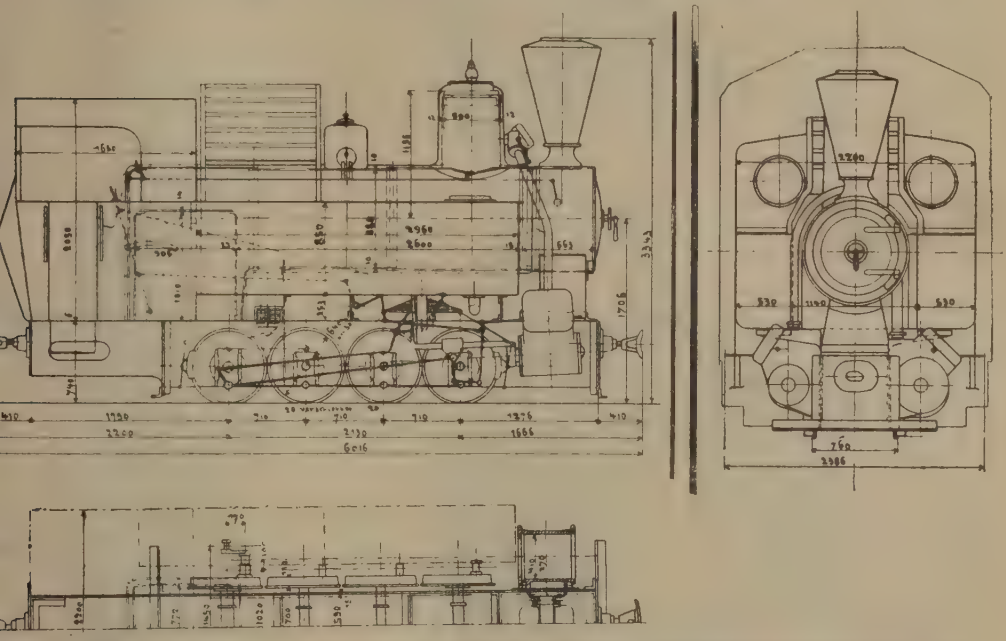
Both types are distinguished by the power produced. The first gives 270 and the second 280 horse-power; these correspond to the high ratios of 3·54 and 3·68 horse-power per centimetre (8·87 and 9·22 British horse-power per inch) of gauge and of 9·76 and 10 57 horse-power per ton (9·78 and 10 59 British horse-power per English ton) of locomotive respectively, and this is due to the rather high working pressure of 13 atmospheres (191·18 lb. per square inch) and to the compounding; these quality coefficients are higher in this case than in that of all the other locomotives of all the gauges which we are dealing with.

Among the other types of locomotives [2] of the Austrian railways, we have to mention the D tank locomotive of the Bukovina Local Railway (fig. 8), which thanks to a high working pressure and to compounding gives 150 horse-power, although

it has the very low axle-load of only 4·2 tons (4·1 English tons) and the small total weight of 16·8 tons (16·5 English tons); thus it gives 8·95 horse-power per ton (8·97 British horse-power per English ton) of locomotive, and must be classified in this respect as belonging to the locomotives of economic design.



8. — Bukovina Local Railway. — D compound tank locomotive, series Cv, gauge 760 millimetres (2 ft. 5 $^{15}/_{16}$ in.).

The Hungarian railways also describe two noteworthy types :

The Arad-Csanad Railway describes a A 1 A tractor in which each pair of driving wheels are on a flexible axle, each driven by a two-cylinder de Dion-Bouton engine with enclosed toothed-gear transmission. The vertical boiler works at a pressure of 18 to 25 atmospheres (265 or 368 lb. per square inch), and the power produced is stated to be 75 horse-power.

The Kaschau-Oderberg Railway describes a D tank locomotive with the large wheelbase of 4,000 millimetres (13 ft. 1 $^{1}/_{2}$ in.). The Klien-Lindner system is applied to the first and to the last axle, so that it can run round curves having a radius of 60 metres (3 chains). As the whole weight of the locomotive is utilized as adhesive weight, the available drawbar pull on the steepest gradient of 22·5 per mil is 3,220 kilograms (7,099 lb.).

The lines described by the railway administrations in the Empire of India, which have a gauge of 762 millimetres (2 ft. 6 in.), show much more favourable

conditions as regards curves and gradients than the lines hitherto considered, as the minimum radius is 73 metres (3·65 chains) on one of the lines and over 100 to 150 metres (5 to 7 1/2 chains) on the others; the gradients are also very moderate and the steepest is only 19 per mil. These conditions of the line exercise a material influence on the design of the more powerful locomotives, so that no proper comparison between them and the locomotives previously described can be made.

Among them we may specially mention
6a) the 1 D 2 tank locomotive of the Bengal-Nagpur Railway, which can take an unusual quantity of stores; its power, according to the standards laid down in the introduction, may be estimated at 290 horse-power. In addition, there is
6b) the 1 D 1 locomotive with separate tender, of the same railway, which gives 410 horse-power, or 5·4 horse-power per centimetre (13·5 horse-power per inch) of gauge; this very good ratio is only exceeded by one American locomotive. The two types are also distinguished by having a great adhesive weight, one being just over and the other just under 28 tons (27·5 English tons); in this respect they also differ materially from the European types. Finally there is a 2 C 1 locomotive
6c) with separate tender, giving 345 horse-power.

8) The North Western State Railway describes, besides a number of locomotives of weaker type, three similar types
b) of 1 C 1 tank locomotives with an adhesive weight of 25·7 tons (25·3 English tons) and giving 275 horse-power.

All of these locomotives are powerful and there is no complicated design in connection with the driving wheels, only the old and simple designs being used; these locomotives are accordingly no doubt distinguished by a low cost of maintenance. One peculiarity is that in spite of the favourable line conditions and in spite of the long flexible wheelbases, a low maximum speed is specified, amounting in all cases to 24·1 kilometres (15 miles) per hour with the solitary exception of the type on the Bombay, Baroda and 9)
Central India Railway, in which case it is 32·2 kilometres (20·0 miles) per hour.

D. — *Railways with a gauge of 785 millimetres (2 ft. 6 29/32 in.).*

Particulars about locomotives of this 1)
gauge have been sent only by the Kattowitz Directorate of the Prussian-Hessian State Railway.

Apart from a series of C tank locomo- a)
tives of moderate power of simple design, of which thirty-nine were built during the years 1876-1901, three noteworthy types are described which are used under rather difficult conditions, the minimum radius being 40 or 35 metres (2 or 1 3/4 chains) and the steepest gradient 40 per mil.

A tank locomotive, of which four were b)
built during the years 1898-1901, is of the C + B type; it has two cylinders; three driving axles are in the main frame and two driving axles are in a bogie, on the Hagans system; the adhesive weight is 27·15 tons (26·72 English tons) the heaviest axle-load being only 5·49 tons (5·40 English tons); the total wheelbase (all axles being driving axles) is large, namely 4,650 millimetres (15 ft. 3 in.), and this corresponds to 5·83 tons per

metre (1·75 English tons per foot) of wheel-base.

On the steepest gradient of 40 per mil this locomotive gives an available draw-

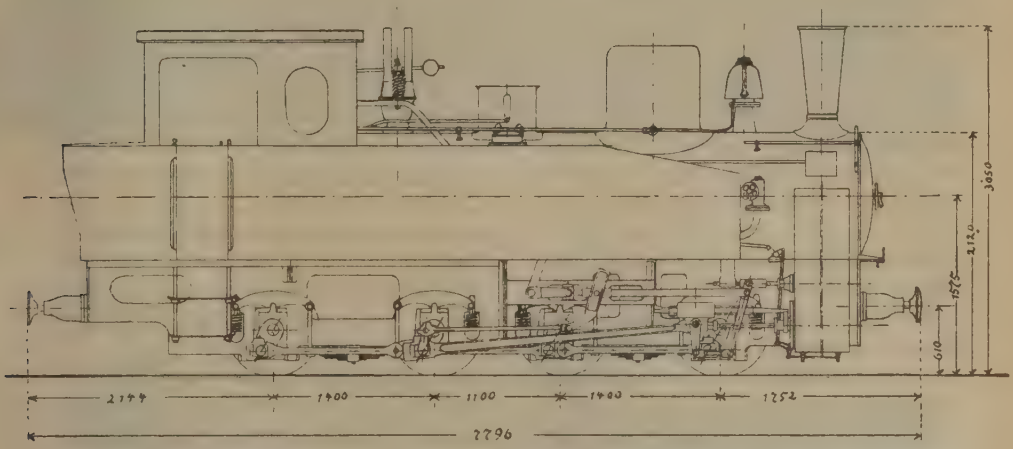

Fig. 11. — Prussian State Railway. Kattowitz Directorate. — D tank locomotive, Klien-Lindner design, used on the Upper Silesia narrow-gauge lines 785 millimetres (2 ft. 6 $^{29}/_{32}$ in.).

bar pull of 3,105 kilograms (6,845 lb.) and develops 220 horse-power, or 8·1 horse-power per ton (8·11 horse-power per English ton) of locomotive.

c and d) Next to these, there are a number of D locomotives (fig. 11) built during the years 1902-1907, which are of two very similar types. The leading and the trailing pairs of wheel have radial play, on the Klien-Lindner system, to allow for curves. These locomotives have shorter wheelbases, greater axle-loads and greater tractive power than the class last described; they work at higher pressure and give about the same power. Owing to the greater simplicity of the transmission of the drive to the axles with radial play, this design is probably preferable in many cases.

E. — *Railways with a gauge of 890 or 891 millimetres (2 ft. 11 $^{3}/_{64}$ in. or 2 ft. 11 $^{3}/_{32}$ in.).*

(Figs. 12 to 17.)

Answers to the list of questions were received from two administrations in Sweden; the answers include one hundred and four locomotives, of ten different types. The narrow-gauge lines in this country have become developed in a peculiar way, for what has been said about the 762 millimetres (2 ft. 6 in.) gauge in India, applies to a still greater extent in the case of these lines, which have by no means the usual character of narrow-gauge lines, but have very favourable conditions both as regards curves and gradients. The minimum radii of the curves

on the open line vary between 148 and 300 metres (between 7·4 and 15 chains), and at switches between 119 and 150 metres (between 5·95 and 7·5 chains); the steepest gradients are between 16 and 27·6 per mil. With such favourable conditions, these lines are better able to cope with a busy traffic than any of the other narrow-gauge lines. These very favourable conditions have made it possible for locomotive designers to increase the size both of the rigid and of the total wheelbase; and a glance at a drawing or illustration of such a locomotive shows that this type is quite different from those hitherto considered; it seems more like a smaller specimen of a standard-gauge locomotive.

The individual axle-loads are not much greater than the maximums hitherto considered, but are all large, and vary between 6·1 and 7·05 tons (between 6 and 6·94 English tons). The adhesive weights do not exceed those hitherto considered, but are mostly near the upper limit; the power is by no means as great as that of the most powerful Indian locomotives, but is near the upper limit of all the others. On the other hand, the speed has been developed to such a degree, that these locomotives not only surpass all those hitherto considered, but also many locomotives used on wider gauges. Except in the case of three types, the maximum speeds are fixed at from 50 to even 65 kilometres (31 to even 40·4 miles) per hour, and the latter makes it possible to have an accelerated passenger-train service on narrowgauge lines. Among them we may
1a) mention a 1 C compound locomotive with separate tender, of the Swedish State Railway; this has a rigid wheelbase of 3,400 millimetres (11 ft. 1 7/8 in.) and a total wheelbase of 5,400 millimetres (17 ft. 8 5/8 in.) and gives 270 horse-power or 11·15 horse-power per ton (11·17 horse-power per English ton) of locomotive; it runs at a speed of 60 kilometres (37·3 miles) per hour.

Then there is a 1 C 1 tank locomotive f) with a rigid wheelbase of 3,000 millimetres (9 ft. 10 in.) and a total wheelbase of 6,275 millimetres (20 ft. 7 in.). It uses superheated steam and gives 280 horse-power, or 8·37 horse-power per ton (8·39 horse-power per English ton) locomotive. The speed authorized is 50 kilometres (31·0 miles) per hour.

The Stockholm-Rimbo Railway des- 2a) cribes three types of which one is a compound 1 C locomotive with separate tender, having a rigid wheelbase of 3,400 millimetres (11 ft. 1 7/8 in.) and a total wheelbase of 5,400 millimetres (17 ft. 8 5/8 in.). This is the most powerful locomotive of this gauge; it gives 275 horse-power or 11·37 horse-power per ton (11·40 horse-power per English ton) of locomotive (tender excluded), and this is the gratest power per unit of weight given by any locomotive with separate tender. Should increasing traffic make it necessary, there will be no difficulty in designing much more powerful locomotives for lines of this character, without having to go in for too much complication.

F. — *Railways having a gauge of 914 millimetres (3 feet).*

(Figs. 18 and 19.)

Four of the railways administrations in the United States have sent descriptions of seventeen classes of locomotives; ele

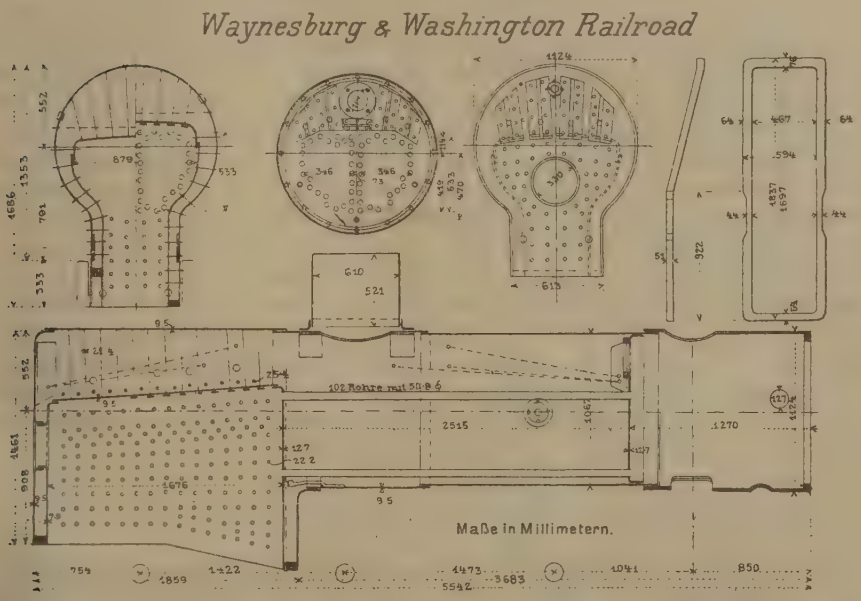

Fig. 19. — Pennsylvania Lines West of Pittsburgh. — Details of boiler of locomotive shown in fig. 18.
Gauge 914 millimetres (3 feet).

Explanation of German terms : 102 Rohre mit 50·8 ϕ = 102 tubes, diameter 50·8 millimetres (2 inches).
Masse in Millimetern = Dimensions in millimetres.

ven types which show material variations, are given in the appendix, while no particulars are given of two lots of three each, as they are very similar to two others. All these locomotives are used on lines where the conditions as to curves and gradients are very difficult.

The minimum radii of the curves on these lines, in so far as they are given in the answers, vary between 47 and 70 metres (between 2·35 and 3 $^1/_2$ chains) on the open line, and the steepest gradients between 25·6 and 82·5 per mil. In spite of these very unfavourable conditions, and without using any unusual design for the driving wheels, considerable power is obtained, in fact four similar types are among the most powerful locomotives about which we have any particulars. This is due in the first place to the magnitude of the individual axle-loads, which all exceed 6·5 tons (6·4 English tons) and in one case attain 12 tons (11·81 English tons). The fixed wheelbases used are much longer than those used in Europe for similar curves. All of them are locomotives with separate tender, which holds a large quantity of stores; and in some cases very high speeds, up to 64 kilometres (39·7 miles) per hour, are considered admissible.

2) The most powerful types are those described by the Chicago, Burlington and Quincy Railroad; they are used for lines with curves having minimum radii of 47 metres (2·35 chains) and steepest gradients of 82·5 per mil. One class of 1 C
a) locomotives with separate tender was built in 1882; there are four very similar types. The adhesive weight is 26·76 tons (26·34 English tons), and the maximum axle-load is 9 tons (8·85 English tons). The large rigid wheelbase of 3,206 millimetres (10 ft. 6 $^1/_4$ in.) is only able to run round the sharp curves, because each of the coupled axles has a lateral play of 4 millimetres ($^5/_{32}$ inch). These locomotives give 275 horse-power, and at the time when they were built this was without doubt much in advance of all other narrow-gauge locomotives.

Four newer types of 1 D locomotives *b*) built in 1900 occupy as regards power the second position among all the locomotives reported. The great adhesive weight of 44·62 tons (43·91 English tons) is combined with a more moderate but still large rigid wheelbase of 3,023 millimetres (9 ft. 11 in.), which is enabled to run round curves in the same way as in the case of the older type, by allowing the axles a little lateral play. The maximum axle-load is 12 tons (11·8 English tons). The total weight of 49·61 tons (48·82 English tons) is carried on at otal whellbase of 5,182 millimetres (17 feet), so that the load per metre of wheelbase amounts to 9·57 tons (2·87 English tons per foot).

The locomotive gives 500 horse-power, or 5·47 horse-power per centimetre of gauge or 10·05 horse-power per ton (14 horse-power per inch or 10·21 horse-power per English ton) of locomotive (tender excluded), and both the road and the roadbed are subjected to considerable fatigue for the purpose.

G. — *Railway having a gauge of 950 millimetres (3 ft. 1 $^3/_8$ in.)*

This class includes one type of locomotive of the Italian State Railway; twelve of these locomotives were built in 1909. The conditions as to curves and gradients are rather difficult; the sharpest curve has

a radius of 100 metres (5 chains) and the steepest gradient is 25 per mil. The axle-load admitted, namely 12·5 tons (12·3 English tons) is the highest reported. This condition makes it possible to design a very powerful type. The adhesive weight of 47·9 tons (47·14 English tons) is distributed over a wheelbase of 3,750 millimetres (12 ft. 3 5/8 in.); the maximum average load per metre of wheelbase is 12·77 tons (12·56 English tons). Under these conditions, assuming the coefficient of adhesion to be 1/6, the available drawbar pull on the steepest gradient is 6,200 kilograms (13,668 lb.). The heating surface of the boiler exceeds 105 square metres (1,130 square feet) and the maximum working pressure is 14 atmospheres (206 lb. per square inch); this makes it possible to develop 430 horse-power or 8·98 horse-power per ton (8·83 horse-power per English ton) of locomotive, so that this locomotives is included among those of economical design.

H. — *Railways having a gauge of 1,000 millimetres (3 ft. 3 3/8 in.).*

As many as seventeen administrations in Germany, the Argentine, Spain, France, Italy, Luxemburg, Portugal, Russia and Switzerland, sent answers about such lines, and as particulars of seventeen different types of locomotives were given, we may conclude that this gauge is the one most in favour. The characters of these lines vary widely; there are minimum radii of 21 and of 450 metres (1·05 and 22 1/2 chains), and the gradients also vary between 8 and 58·82 per mil, so that no general representation of the conditions is possible. Accordingly the designs of the locomotives also vary within wide limits, and besides typically narrow-gauge light specimens we also find very heavy types. Most of the German lines are of a difficult character, and for these tank locomotives are exclusively used; we may draw attention to the following :

1b) One type of the Alsace-Lorraine State Railway. This is a D locomotive used on curves with a minimum radius of 50 metres (2 1/2 chains) and has the large adhesive weight of 28·65 tons (28·19 English tons); the trailing pair of wheels, in a Bissel truck, is driven by a loose axle, and in this way the large wheelbase (coupled wheels only) of 3,400 millimetres (11 ft. 2 in.) is obtained.

2a) The Bavarian State Railway describes a 1 C type for a line on which the sharpest curves have a radius of only 21 metres (1·05 chains), and in spite of these difficult conditions it obtains a similar adhesive weight by having a greater individual axle-load, namely 8·3 tons (8·2 English tons).

3c) The Erfurt Directorate of the Prussian-Hessian State Railway describes, among others, (fig. 20 to 22) a D tank locomotive which is designed for curves having a radius of 40 metres (2 chains) and has an adhesive weight of 29·67 tons (29·20 English tons), the maximum axle-load being only 7·6 tons (7·48 English tons). This result is obtained by having for the fourth pair of coupled wheels an adjustable hollow-axle; the total wheelbase (coupled wheels only) is 3,300 millimetres (10 ft. 9 15/16 in.) and the load per metre of wheelbase is 9·0 tons (2·70 English tons per foot).

4) The Saxon State Railway has a class of B + B compound locomotives (fig. 23) with four cylinders, on the Fairlie sys-

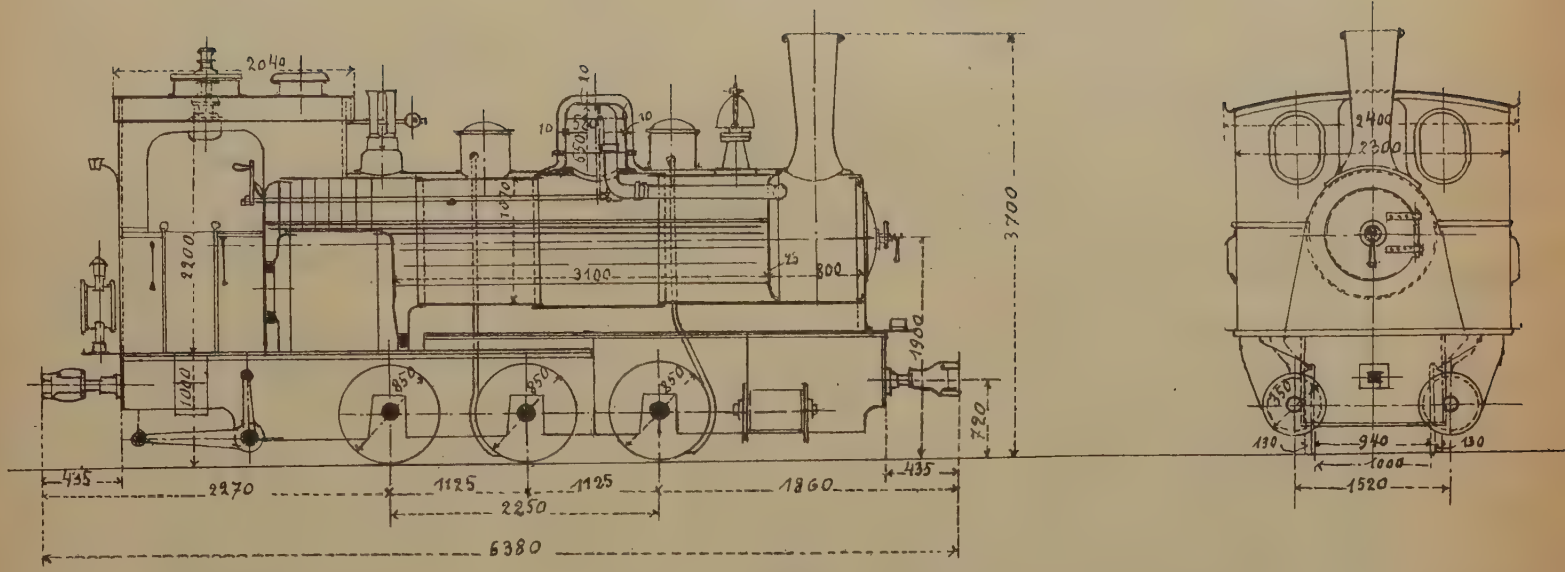

Fig. 20. — Prussian State Railway, Erfurt Directorate.

Explanation of German terms : Feuerrohre = Smoke tubes. — Kesselmitte = Centre line of boiler. — Leergewicht = Weight, empty. Dienstgewicht = Weight in working order. — Gesamtgewicht = Total weight.

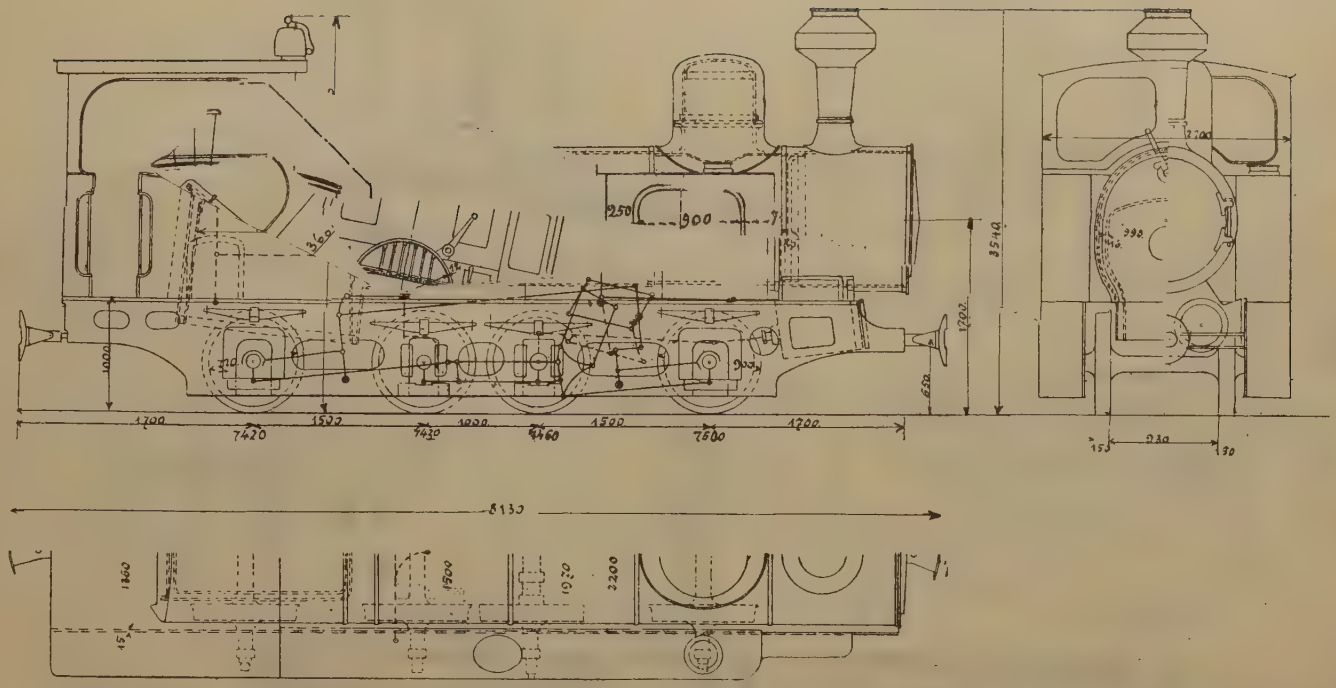

Fig. 24. — Wurtemberg State Railway. — D tank locomotive, type Ts_4, gauge 1 metre (3 ft. 3 3/8 in.). Used on the Nagold-Altensteig line.

tem, designed for curves having a minimum radius of 30 metres (1 1/2 chains) on the open line and of 25 metres (1 1/4 chains) at swiches. This locomotive has an adhesive weight of 41·8 tons (41.14 English tons), and the high maximum axle-load of 10·6 tons (10·4 English tons). The weight is well distributed by the wheelbase of 7,600 millimetres (24 ft. 11 1/4 in.), so that the load only amounts to 5·5 tons per metre (1·65 English tons per foot) of wheelbase. On the steepest gradient of 25 per mil, the available drawbar pull, on the same assumptions as made in the previous cases, is 5,460 kilograms (12,037 lb.).

The locomotive gives 395 horse-power, or 9·43 horse-power per ton (9·47 horse-power per English ton) of locomotive. Taking into consideration the sharp curves on which this locomotive is used, and its dimensions, it must be described as one of the most powerful types of its kind.

6) The Argentine Northern Railway has very favourable line conditions; the minimum radius is 450 metres (22 1/2 chains) on the open line and 180 metres (9 chains) at switches, the steepest gradient being 12 per mil. It accordingly has more of the character of a line for long-distance traffic. The locomotives, which all have a separate tender, could be made very powerful without adopting any unusual design.

6a) One type is a 2 C locomotive with an adhesive weight of 32·98 tons (32·46 English tons) and a maximum axle-load of 11·5 tons (11·3 English tons). Wood is used for firing; a locomotive of similar dimensions but arranged for coal firing would develop about 460 horse-power.

8) The Orleans Railway describes, besides a number of lighter types of older construction, a B + B compound locomotive (fig. 25) with four cylinders, on the Mallet system, for use on a line having curves with a minimum radius of 100 metres (5 chains) and steepest gradients of 30 per mil. This is very similar, as regards power and tractive effort, to the type of the same group described under 4); but it has a small total wheelbase, although the wheelbase of each of the driving bogies is larger.

10) The St. Quentin-Guise and Aisne Department Railway, for a line with steepest curves having a radius of 40 metres (2 chains) and steepest gradients of 44 per mil, has had built three light B2 automotors, with vertical boiler, having a total weight of 24 tons (23.6 English tons). b)

Descriptions of the locomotives of other narrow-gauge lines have also been sent by French railway administrations. These lines are either favourably placed as regards curves and gradients, or there seems no particular need for high powers, so that the locomotives could be designed, the axle-loads being rather high, in a simple way without using complicated engines.

13) The Portuguese National Railway Company has lines with favourable curves and gradients (radii 150-100 metres [7 1/2-5 chains] respectively and gradients of 18 per mil) and besides a lighter type also b) uses a 1 C tank locomotive which has the moderate total weight of 32 tons (31·5 English tons) and develops 325 horse-power, or 10·2 horse-power per ton (10·22 horse-power per English ton) of locomotive; this shows a proper economy in the design.

14) The Riazan-Ural Railway has no difficul-

ties to overcome on its line. The locomotives have separate tenders, are of simple design and of medium size; as naphtha is used for firing, much more power is obtained with heating surfaces of moderate sizes, than would be possible with coal.

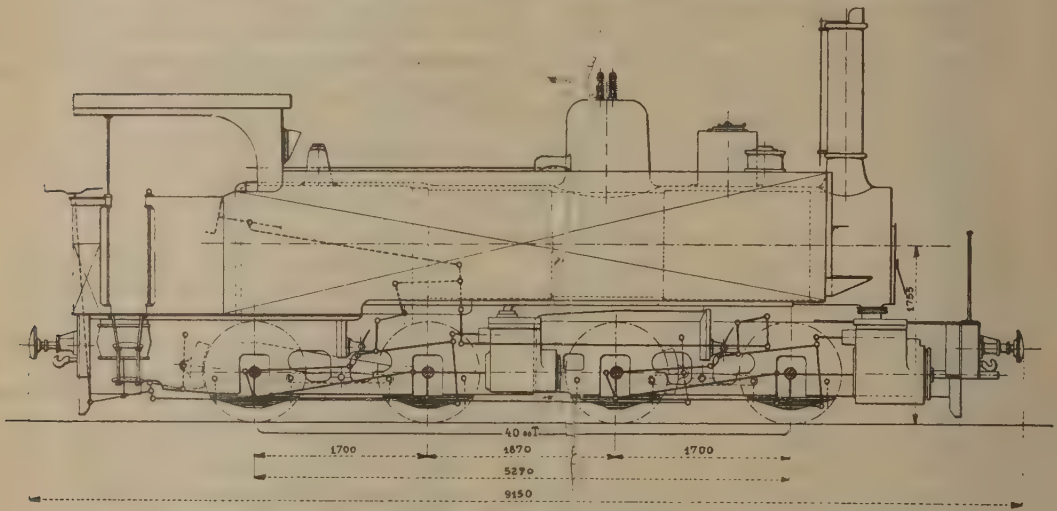

Fig. 25. — Orleans Railway. — Compound tank locomotive, Mallet system. Used on the Corrèze line.

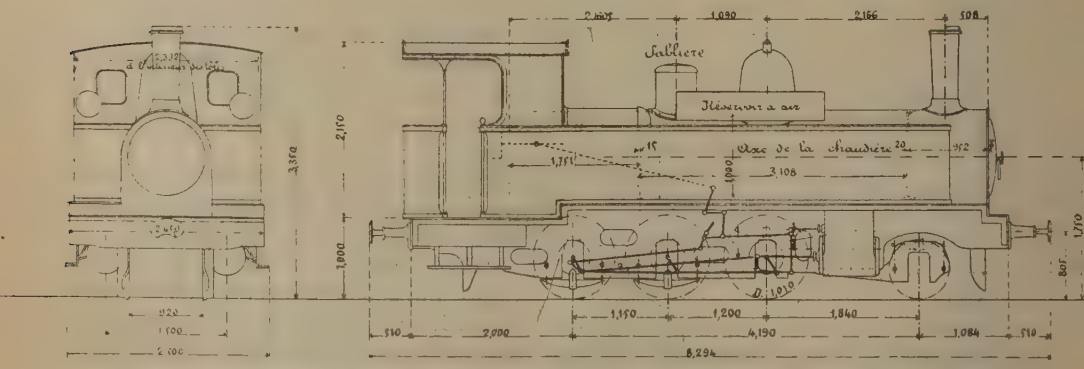

Fig. 26. — Paris-Lyons-Mediterranean Railway. — 1 C tank locomotive used on the Orange-Buis-les-Baronnies line.

Explanation of French terms : A l'intérieur des tôles = Inside the plates.
Sablière = Sanding apparatus. — Axe de la chaudière = Centre line of boiler. — Réservoir à air = Air reservoir.

16) The Rhetian Railway (Switzerland) sends particulars of a 1 D locomotive with separate tender (fig. 29) for a line on which the sharpest curves have a radius of 100

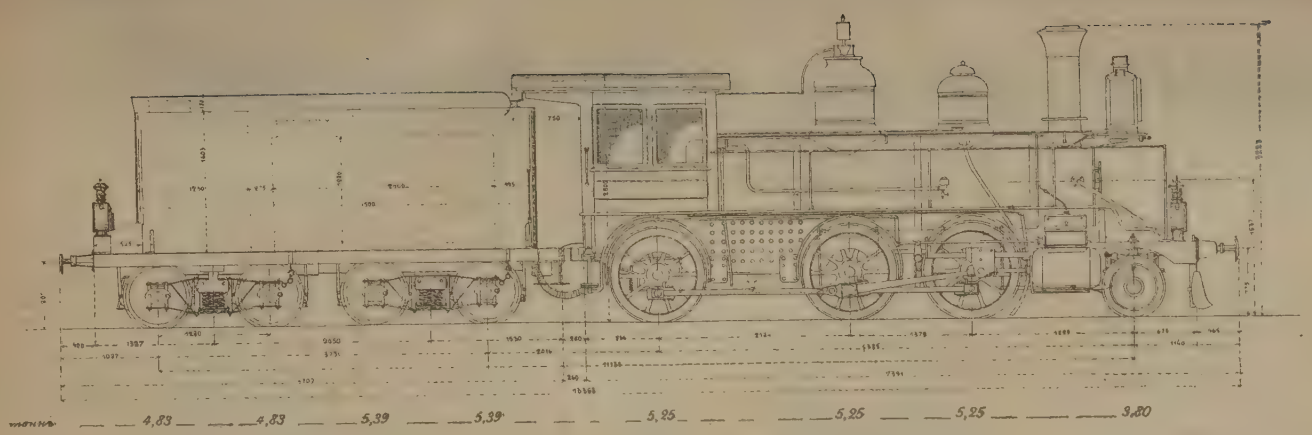

Fig. 27. — Riazan-Ural Railway.

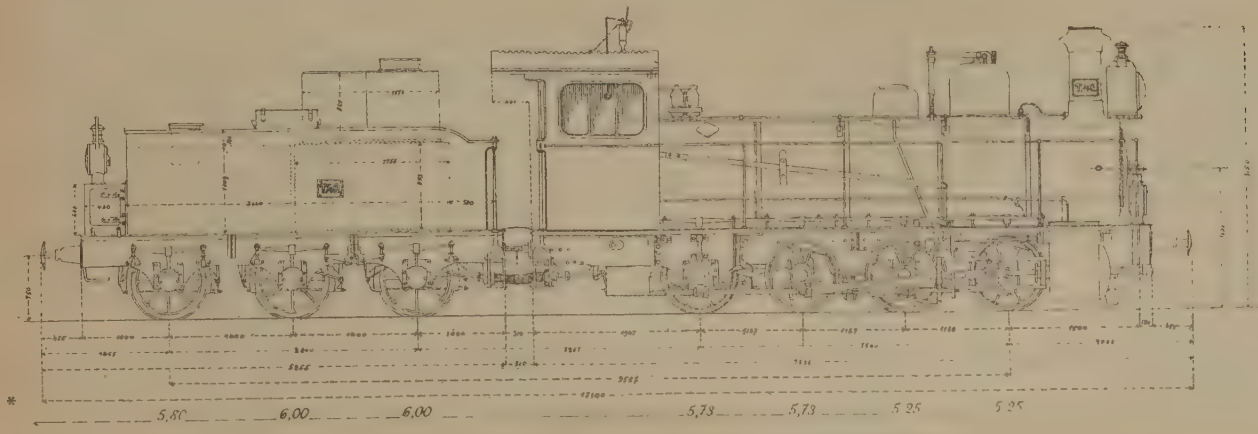

Fig. 28. — Riazan-Ural Railway.

metres (5 chains) on the open line and of 90 metres (4 $^1/_2$ chains) at switches, and the steepest gradient is 45 per mil. The maximum axle-load is rather high with this type, namely 10·62 tons (10·45 English tons); the adhesive weight is 41·6 tons (40·9 English tons) and the total weight is 46·98 tons (46·23 English tons), which are distributed by wheelbases of 4,050 and 6,100 millimetres (13 ft. 3 $^1/_2$ in. and 20 feet) respectively, and give the moderately-high average load of 7·7 tons per metre (2·31 English tons per foot) of wheelbase. The steam is superheated and used at a medium pressure; the greatest amount of power is obtained, namely 520 horse-power, or 11·1 horse-power per ton (11·12 horse-power per English ton) of locomotives tender excluded; this ratio is also a very good one.

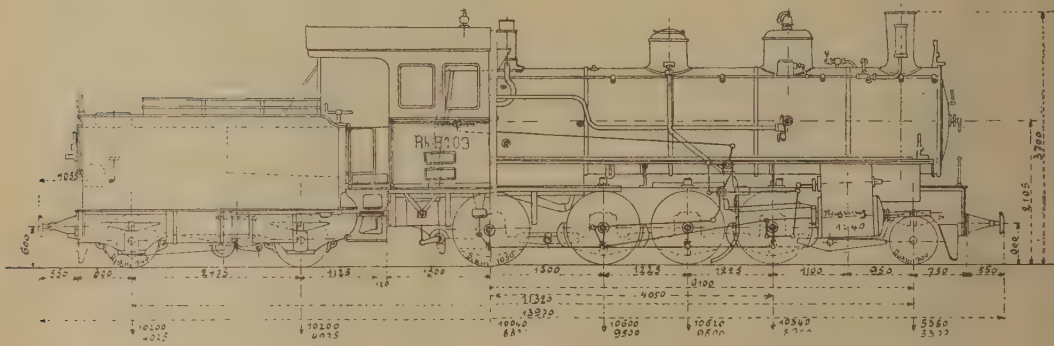

Fig. 29. — Rhetian Railway. — 1 D two-cylinder superheated-steam locomotive.

J. — *Railways having a gauge of 1,067 millimetres (3 ft. 6 in.).*

The curves on the line having this gauge are in most cases very easy, and the gradients, except in one case, also present no difficulties; the locomotives built for operating the traffic on these lines differ but little, as far as dimensions and power are concerned, from the average of the narrow-gauge locomotives already considered, except as regards the high admissible speeds, which amount to from 56 to
2) 60 kilometres (34·8 to 37·2 miles) on the Norwegian State Railway and to 50 kilo-
3) metres (31 miles) per hour on the Moscow-Vindau-Rybinsk Railway and on the Swiss Federal Railway; these are among the
4) highest speeds reported. Quite apart from the question of the dimensions and the powers, we must not leave out of consideration the large number of locomotives (561) which the Belgian National Suburban
1) Railway Company has had built of only two types, so obtaining all the advantages of work on a large scale both as regards the operation of the traffic and the maintenance of the locomotives, in a way to which no other administration has even approximated. The high adhesive weight of 29 tons (28 5 English tons) when there are curves with a radius of 25 metres (1 $^1/_4$ chains) is also noteworthy and is made possible by the axle-load of 9·7 tons (9·5 English tons).

3. — Chief properties of the locomotives.

A considerable number of particulars and figures have been given of the locomotives which in consequence of any special feature were described in the preceding sections; in order to facilitate a general view of the subject, we give a table containing a selection of the more powerful types of all gauges, which includes those locomotives which are specially remarkable from the following points of view :

a) Absolute horse-power;
b) Horse-power per centimetre of gauge;
c) Horse-power per ton of locomotive;
d) Adhesive weight;
e) Individual axle-loads;
f) Ratio of adhesive weight to radius of curves which are on the line concerned.

In each case the three highest values are underlined :

If we now consider the measures which have been taken in order to improve the limited quality coefficients of the older designs, we can make the following general remarks :

A. — *The power of the locomotives was increased :*

1° By increasing the working pressure;
2° By superheating the steam;
3° By the introduction of compounding.

Indirectly this also incluces the devices enabling the axles to adjust themselves to curves, in the case of those wheelbases which correspond to the weight of the engine required for a given power and to the admissible loads on the road-bed. The devices however only give difficulty if the adjustable axles are to be driving axles, and tend to increase the adhesive weight.

a) The working pressures which are used vary between 8 and 14 metric atmospheres (between 117·6 and 206 lb. per square inch) and their distribution as regards types of locomotives, leaving gauge out of consideration, is shown in the table given below. We have left the pressure in the vertical boiler of one tractor, of 18 to 25 atmospheres (264·7 to 368 lb. per square inch), out of consideration, and only take the figures for ordinary locomotive boilers :

Up to

8, 9, 10, 11, 12, 13, 14 atmospheres (117·6, 132·4, 147, 161·8, 176·5, 191, 206 lb. per square inch).

Were used on

3, 1, 18, 18, 41, 15, 4 types of locomotives.

The pressure of over 12 and up to 13 atmospheres (over 176·5 and up to 191 lb. per square inch) is already in use on the types in question since 1896; they include :

Two types of the Prussian-Hessian State Railway (gauge 785 millimetres [2 ft. 6 $^{29}/_{32}$ in.], items 1*c* and *d*);

Three types of the Austrian State Railway (gauge 760 millimetres [2 ft. 5 $^{29}/_{32}$ in.], items 1*a* to *c*);

Four types in the United States of America (gauge 914 millimetres [3 feet], item 2 *b*);

Three types in India (gauge 762 millimetres [2 ft. 6 in.], item 8*b*);

One type of the Norwegian State Rail-

way (gauge 1,067 millimetres [3 ft. 6 in.], item 2*c*);

Two types of the Stockholm-Rimbo Railway, in Sweden (gauge 891 millimetres [2 ft. 11 $^{3}/_{32}$ in.], item 2*a*).

The pressure of over 13 and up to 14 atmospheres (over 191 and up to 206 lb. per square inch) is in use on only four types, since 1901; they include :

Two types of the Saxon State Railway (gauge 750 millimetres [2 ft. 5 $^{1}/_{2}$ in.], item 1*b*);

One type of the Orleans Railway (gauge 1,000 millimetres [3 ft. 3 $^{3}/_{8}$ in.], type $8c_2$);

One type of the Italian State Railway (gauge 950 millimetres [3 ft. 1 $^{3}/_{8}$ in.]).

This very productive measure for increasing the power, which requires much less than a proportionate increase in the weight of the boilers, could be applied all the more readily in the case of narrow-gauge locomotives, as the increase of temperature corresponding to an increase of pressure produces, in consequence of the smaller dimensions of the fire-boxes, a smaller expansion of the latter as compared with the outer shell than in the case of large fire-boxes. Consequently, the stays and their connexions with the plates are subjected to smaller bending stresses than in the case of large fire-boxes, and accordingly they resist better.

b) As regards superheating of the steam, much fewer data are available. There are six types of such locomotives, namely :

One type of the Bavarian State Railway, working pressure 12 atmospheres (176·5 lb. per square inch) (gauge 1,000 millimetres [3 ft. 3 $^{3}/_{8}$ in.] item 2*a*);

Three types of the Swedish State Railway, working pressure 11 atmospheres (161·8 lb. per square inch) (gauge 890 millimetres [2 ft. 11 $^{3}/_{64}$ in.], items 1*f* and 1*g*), and 10 atmospheres (147 lb. per square inch) (gauge 1,067 millimetres [3 ft. 6 in.], item 4);

One type of the Stockholm-Rimbo Railway, working pressure 11 atmospheres (161·8 lb. per square inch) (gauge 891 millimetres [2 ft. 11 $^{3}/_{32}$ in.], item 2*c*);

One type of the Rhetian Railway, working pressure 12 atmospheres (176·5 lb. per square inch) (gauge 1,000 millimetres [3 ft. 3 $^{3}/_{8}$ in.], item 16).

The use of these locomotives dates back to 1906, and it is probable that the fuel economy which can be realized in this way was an important factor in the selection of this system. As far as available information shows, the steam is superheated to 300° C. (572° Fahr.).

c) Compounding already came into use in 1892; fourteen types are described, five of them with four cylinders. They are used by the following administrations :

Three types of the Saxon State Railway, with four cylinders, working pressure 12 atmospheres (176·5 lb. per square inch) (gauge 750 millimetres [2 ft. 5 $^{1}/_{2}$ in.] item 1*a*), and 14 atmospheres (206 lb. per square inch) (item 1*b*); also with four cylinders, working pressure 14 atmospheres (206 lb. per square inch) (gauge 1,000 millimetres [3 ft. 3 $^{3}/_{8}$ in.], item 4);

One type of the Wurtemberg State Railway, with four cylinders, working pres-

sure 12 atmospheres (176·5 lb. per square inch) (gauge 750 millimetres [2 ft. 5 1/2 in.], item 2);

Two types of the Austrian State Railway, working pressure 13 atmospheres (191 lb. per square inch) (gauge 760 millimetres [2 ft. 5 15/16 in.], items 1*b* and 1*c*);

One type of the Bukovina Local Railway, working pressure 13 atmospheres (191 lb. per square inch) (gauge 760 millimetres [2 ft. 5 15/16 in.], item 2);

One type of the Arad-Csanad Railway, with two de Dion Bouton two-cylinder motors, working up to a pressure of 25 atmospheres (368 lb. per square inch) (gauge 760 millimetres [2 ft. 5 15/16 in.], item 4);

One type of the Orleans Railway, with four cylinders, working pressure 14 atmospheres (206 lb. per square inch) (gauge 1,000 millimetres [3 ft. 3 3/8 in.], item 8c_2);

Two types of the Norwegian State Railway, working pressure 12 atmospheres and 13 atmospheres (176·5 and 191 lb. per square inch) (gauge 1,067 millimetres [3 ft. 6 in.], items 2*a* and 2*c* respectively);

One type of the Riazan-Ural Railway, working pressure 11 atmospheres (161.8 lb. per square inch) (gauge 1,000 millimetres [3 ft. 3 3/8 in.], item 14*b*);

One type of the Swedish State Railway, working pressure 12·5 atmospheres (183·8 lb. per square inch) (gauge 890 millimetres [2 ft. 11 3/64 in.], item 1*a*);

One type of the Stockholm-Rimbo-Railway, working pressure 12·5 atmospheres (183 8 lb. per square inch) (gauge 891 millimetres [2 ft. 11 3/32 in.], item 2*a*).

The use of four cylinders is in all cases to be attributed to the use of two separate driving bogies.

B. — Finally, we have to consider the designs which result in an increase of the adhesive weight beyond that which is attainable when a rigid wheelbase is used.

These measures, leaving out of consideration play of the axle-boxes and the use of flangeless wheels on some of the coupled axles, can be divided into two chief classes :

1° The use of separate wheel pairs having radial play;

2° The use of bogies with the axles in a separate frame.

In both cases, the axles can be actuated either by purely mechanical transmission from one central complete steam engine, or each set of axles can have a separate engine. Particulars of altogether thirteen such designs are given, in which the object desired is attained more or less completely, though the designs are complicated ; there are eight types with single pairs of wheels and five types with separate motor bogies.

Leaving out of consideration a tractor [1] with two flexible axles, each with separate drive (gauge 760 millimetres [2 ft. 5 15/16 in.], item 4), which properly speaking is not to be included in this class, as in this case there is no question of obtaining a large adhesive weight, there are left seven types of tank locomotives, all of the D class, which utilize their whole weight as adhesive weight, and have axles which are radially adjustable.

These include eleven locomotives of

two types for a gauge of 1,000 millimetres (3 ft. 3 3/8 in.), namely :

One type (item 1*b*) of the Alsace-Lorraine State Railway;

One type (item 3*c*) of the Erfurt Directorate.

Both of these types have one such axle, while the following twenty-seven locomotives of five types each have two radially-adjustable axles, namely :

One type (gauge 750 millimetres [2 ft. 5 1/2 in.], item 1*b*) of the Saxon State Railway;

One type (gauge 760 millimetres [2 ft. 5 15/16 in.], item 5) of the Kaschau-Oderberg Railway;

One type (gauge 785 millimetres [2 ft. 6 29/32 in.], items 1*c* and 1*d*) of the Kattowitz Directorate;

One type (gauge 1,000 millimetres [3 ft. 3 3/8 in.], item 5) of the Wurtemberg State Railway.

The type last mentioned is of the Klose design, and was built 1891-1899; all the others were equipped with hollow axles on the Klien-Lindner system and were built 1901-1908.

These arrangements make it possible to obtain an adhesive weight of from 24 to nearly 30 tons (23·6 to nearly 29·5 English tons), with separate axle-loads not exceeding 6 to 7·6 tons (5·9 to 7·5 English tons), and to have wheelbases of 3,900 to 4,050 millimetres (12 ft. 9 9/16 in. to 13 ft. 3 1/2 in.), able to run over curves having a minimum radius of down to 40 metres (2 chains) on the open line and 35 metres (1 3/4 chains) at switches.

2) Among the designs with two motor bogies there is one type for a gauge of 785 millimetres (2 ft. 6 29/32 in.) (table 3, item 1*b*); this is on the Hagans system. The twin engine not only actuates the three fixed axles of the main frame, but the power is also transmitted, by means of a flexible transmission, to the two axles of the bogie. *a*)

Although the maximum axle-load of this locomotive is less than in the cases previously mentioned and only amounts to 5·5 tons (5·4 English tons), yet as there are five pairs of coupled wheels an adhesive weight of over 27 tons (26·5 English tons) is attained; the locomotive has a wheelbase of 4,650 millimetres (15 ft. 3 in.) and runs over curves having a minimum radius of 40 metres (2 chains) on the open line and of 35 metres (1 3/4 chains) at switches. These locomotives were acquired in the years 1898-1901.

By far the greatest adjustability of large wheelbases to sharp curves, is obtained by the use of two separate motor bogies, worked by two separate and complete engines. The administrations have sent particulars about four such types, namely: *b*)

Two types with two motor bogies of the Meyer and Fairlie design, capable of movement relatively to the main frame of the locomotive. *α*)

Forty-five locomotives of the first type have been built during 1892-1908 for a gauge of 750 millimetres (2 ft. 5 1/2 in.) (item 1*a*); three of the second were built in 1902, with their characteristic double-locomotive-boiler; these were all built for the Saxon State Railway.

Also two types with driving gear which consists of two fixed axles in the main frame, and of a complete motor bogie with a separate pair of cylinders, with two *β*)

axles in the bogie frame, and with the bogie centre placed near the middle of the centre line of the main frame, on the Mallet-Rimrott system.

Two types of B + B tank locomotives have been built on this system, one for the Wurtemberg State Railway (gauge 750 millimetres [2 ft. 5 1/2 in.], item 2) and one for the Orleans Railway (gauge 1,000 millimetres [3 ft. 3 3/8 in.], item 8), during the years 1899-1908.

Generally speaking, the adhesive weight obtained, for the same maximum axle-load, with these B + B locomotives is not greater than in the case of the D locomotives with adjustable coupled axles. On the other hand, the wheelbase can be made much longer, so that there is a better distribution of the load per metre of track and consequently it is easier with this design, than with that with separate adjustable axles, to obtain a greater adhesive weight without greater fatigue of the road-bed, if the track is strong enough. Actually maximum axle-loads of 5·94 to 10·6 tons (5·84 to 10·4 English tons) have been used, so that the resulting adhesive weight has been 27·15 tons (26·72 English tons) and upwards, and even attained 41·8 tons (41·1 English tons).

The wheelbases vary between 4,400 and 7,600 millimetres (between 14 ft. 5 in. and 24 ft. 11 in.), and they adjust themselves so well on curves, that the locomotives with the largest wheel-base are used on curves with a minimum radius of 30 metres (1 1/2 chains) on the open line and of 25 metres (1 1/4 chains) at switches; it is true that the shortest straight between reverse curves is 10 metres (32 ft. 10 in.), and the bogie centres are 6,500 millimetres (21 ft. 4 in.) apart; the two bogies can hence never be simultaneously on reverse curves.

This adjustability of the locomotives on sharp curves is illustrated in the comparative tables given by the ratios " Adhesive weight : curve radius "; it is obtained it is true at the cost of a very undesirable complication of the gear and of flexible steam-pipe connexions, which make maintenance difficult and expensive.

4. — General conclusions.

Having now examined in detail the different types of locomotives for narrow-gauge lines as regards the tractive effort and power developed, as well as the departures from old practice in order to improve the good qualities of the locomotives generally, we may assert with satisfaction not only that locomotive builders have always been able to meet the most severe demands made when new lines were schemed, but also that during the few tens of years that such lines have been operated, quality coefficients have been obtained which in many cases are twice as good as at first, and in some cases have improved even much more. This progress is all the more meritorious, because at the time when most of the narrow-gauge railways were built, the designs of standard-gauge locomotives had already reached a high standard of excellence, and when the construction of narrow-gauge locomotives was begun much better appliances were available than is generally the case with a new branch of industry.

Now, however satisfactory these considerations may be, we must not dwell any further on them, for the question of the latest locomotive types could not have as

its sole object the collection of data, although these are of considerable value for determining the capacity of such lines; but what formed its real object were the conclusions, to be drawn from the large total of the brain work which has been devoted in each individual case to the design of the different types, in the manufacturing countries of the whole world.

If in the first place we examine the influence exercised by the plan and profile of the line and the strength of the track on the development of the locomotives in order to ascertain how to obtain the most favourable combination of track and of operation, we come to the logical conclusion that in the case of new lines the track should be designed to suit those properties of the locomotives, which can be at present obtained with good designs, and which are required not only for the traffic immediately to be expected, but also for a traffic which has increased to a corresponding extent.

Starting from this point of view, we will in what follows enumerate, and give reasons for, those proposals which we should as a rule recommend, when it is a question of building new narrow-gauge lines for public traffic, to be operated by means of steam locomotives.

In the second place, we have to consider the measures which are advisable when acquiring new locomotives for existing lines, so as to obtain the power necessary for coping with the growing traffic, if the existing older types no longer suffice for this purpose.

Although these two points are not expressly laid down in the original wording of the question which is to be discussed, yet they necessarily follow from the examination of the subject, and indeed, what other body or corporation could be more able and more justified to recommend the adoption of certain principles, recognized as advantageous, than the Congress of the administrations who operate the existing lines and not only have acquired wide experience on the subject, but also have suffered from the consequences of difficulties in operation, which have in many cases resulted from small economies at the time of construction?

In the case of the separate points which are to be considered, we give in each case the position taken by the German *Verein* as laid down in " Grundzüge für den Bau und die Betriebseinrichtungen der Lokalbahnen nach den Beschlüssen der Vereins-Versammlung vom 3/5 September 1908 zu Amsterdam. Herausgegeben und verlegt von der geschäftsführenden Verwaltung des Vereins " (Berlin, 1 January 1909), and we will quote this, according to the established practice of the *Verein*, under the abbreviated designation *Grz*.

It is true that these principles are not of themselves applicable by the International Railway Congress, because the ground covered is much larger, and because it is by no means the case that all principles which may give excellent results in individual cases, can also be applied generally, particularly if the necessary preliminary conditions are not the same; they are however of such importance from the point of view of narrow-gauge railways, that on the one hand they could not be omitted without leaving lacunæ, and on the other they give many important points useful in the solution of the question generally.

The subject itself may be subdivided as follows :

A) *Track :*

1° Gauge;
2° Gradients;
3° Curves;
4° Wheel-loads.

B) *Locomotives :*

1° Increase of power :
  a) Working pressure;
  b) Superheating;
  c) Compounding.
2° Increase of adhesive weight.

A. — *Conclusions as regards track.*

1° The evolution of such a large number of different gauges, as described above, which in many cases only show very small differences, cannot be looked upon as an absolute necessity for the proper designing of the lines; and taking into consideration the resulting increase in the number of locomotive types and their consequent greater cost of construction and of maintenance, the selection of any other gauge than those already in existence must be looked upon as disadvantageous to the development of the narrow-gauge railway industry.

Taking into consideration that it has been possible to construct metre (3 ft. 3 3/8 in.) gauge locomotives which can run round as sharp curves as locomotives of smaller gauge, curves with a radius of as little as 30 metres (1 1/2 chains) and in one case even of 21 metres (1·05 chains), and also taking into consideration that it is possible to design, for this gauge, locomotives of considerable power, more capable of operating a growing traffic than would be the case with a narrower gauge, the gauge of 1 metre (3 ft. 3 3/8 in.) is particularly recommended in all those cases in which the new line which is to be built is not in direct connection with a narrow-gauge line of another gauge.

The German *Verein* has laid down the following conclusions in *Grz.*, paragraph 2, section 2 :

> The gauge of 1,000 millimetres or of 750 millimetres (3 ft. 3 3/8 in. or 2 ft. 5 1/2 in.) is recommended for narrow-gauge local lines. In the case of minor railways a gauge of 600 millimetres (1 ft. 11 5/8 in.) is still admissible. If a narrow-gauge system of larger extent, having another gauge, already exists, it is advisable also to select this gauge for an new lines added to it.

Such a narrow limitation of the same fundamental principle is hardly applicable in the case of the Congress, and it is probable that the general recommendation of a gauge of 1 metre (3 ft. 3 3/8 in.), without excluding other gauges which already exist, would better suit the objects which we are here considering; and it might be added that for lines which are to carry public traffic, the gauge of 600 millimetres (1 ft. 11 5/8 in.) is the smallest which can be recommended.

2° The gradients used on the different lines show much variety and it may here be mentioned that longer gradients of 25 to 30 per mil are reported by nine administrations, of up to 35 per mil by six, of up to 40 per mil by three and of up to 45 per mil by three administrations, while gradients of 58·8, 70 and 82·5 per mil

were each reported by one administration, and we may assume that the latter is the limit of what is ordinarily practicable in this way.

The development of the locomotive is not so much hampered by the presence of steep gradients, as it is by the other difficulties presented by the track. On the other hand, for a given horse-power, the gross ton-mileage is materially reduced by the reduction of the train weight including the load on the carrying wheels of the locomotive and of the tender, if any, proportionately to the adhesive weight of the locomotive.

This circumstance makes it evident that it is uneconomic to have excessive gradients on lines where the trains are hauled by steam locomotives, and this the more so, the smaller the ratio of the length of the steep gradients to the total length of the line.

Grz. prescribes in this respect in paragraph 21, section 1 :

> The gradient on adhesion railways shall as a rule not exceed 40 per mil (1 : 25),

and then adds provisions as to gradients on railways and as to easing off changes of gradients, which are outside the scope of this report.

The main statement quoted can be recommended in its general form, as it expresses that it is desirable not to have gradients steeper than 40 per mil; the qualification " as a rule " allows the engineer planning the line to select steeper gradients in special cases after careful consideration of all the circumstances, for and against, particularly of the higher initial outlay or cost of working.

3° The curves also show very great differences; we find everything from a very large minimum radius down to a radius of 21 metres (1·05 chains), as has already been mentioned under heading 1, " gauge ", of this summary.

These dimensions have a very great effect both on the service and on the design of the locomotives.

In the first place, they affect the admissible speed, and we will here only note that the maximum reported speeds of over 50 and up to 65 kilometres (over 31 and up to 40·4 miles) per hour are as a rule limited to lines having curves with a minimum radius of 180 metres (9 chains), while one administration reports a minimum radius of 70 metres (3 1/2 chains) and a maximum admissible speed of 64·4 kilometres (40·0 miles) per hour. We may assume that this speed is not usual on the sharp curves. On sharper curves, the maximum admissible speeds, for which the locomotives are designed, are reduced correspondingly, on the average to about 40 kilometres (25 miles) per hour with radii of 60 metres (3 chains) and to about 30 kilometres (18·6 miles) per hour with radii of 40 metres (2 chains).

Grz. prescribes in this respect in paragraph 22, section 1, clause c :

> The radius of curves on narrow-gauge lines shall as a rule not be less than :
>
> 50 metres (2 1/2 chains) on lines with a gauge of 1,000 millimetres (3 ft. 3 3/8 in.).
> 40 — (2 —) — — of 750 — (2 ft. 5 1/2 in.).
> 25 — (1 1/4 —) — — of 600 — (1 ft. 11 3/8 in.).

Smaller radii can be used on all these lines, if the rolling stock is specially designed for running round sharp curves.

Then prescriptions follow as to the transition curves and the length of straights between reverse curves, which are to be at least 10 metres (32 ft. 10 in.) in length between the two superelevation gradients.

If the three dimensions here considered: gauge, rigid wheelbase and radius of curve, are directly proportionate to each other, the axles of the vehicles in all cases form the same angles with the radii of the curve.

But as the length of the locomotives and consequently of the most advantageous wheelbase does not decrease proportionately to the gauge, the need arises not to establish a direct proportion between the gauge and the radii of the curves, but to have a greater ratio between these two dimensions in the case of narrower gauges than in that of wider gauges.

Taking this circumstance into consideration, and also the existing lines, it seems advisable to place the matter on a simpler basis and to recommend the general adoption of the radius of 40 metres (2 chains) as a minimum, and to make any further reduction in this dimension dependent on the use of rolling stock which is so equipped that the axles have the required adjustability on the curves.

The straights between reverse curves should be at least as long as the greatest distance between bogie centres of any vehicle, if no guard rails are laid at these curves.

4° The admissible axle-loads and the admissible loads per metre of track are, among all the conditions mentioned, the most important factors in the designing of powerful locomotives, particularly in the case of lines with steep gradients.

When we considered the different types of locomotives, we drew particular attention to the fact that some of the most powerful locomotives, giving the greatest tractive efforts, were designed for lines with very unfavourable curves, as it was possible to have great axle-loads.

Grz. prescribes, under construction and maintenance of rolling stock, in paragraph 41, section 2 :

The following maximum wheel-loads, measured in a state of rest, are recommended for the following gauges :

Gauge	1 metre.	750 millimetres,	600 millimetres;
	(3 ft. 3 3/8 in.),	(2 ft. 5 1/2 in.),	(1 ft. 11 5/8 in.);
Wheel-load . . .	4·5 tons,	4 tons,	3·5 tons.
	(4·4 English tons),	(3·9 English tons),	(3·4 English tons).

Now it is true that these maximum wheel-loads recommended, or the corresponding double axle-loads are not attained in many cases on the lines about which the administrations have sent us information, but in many cases they are materially exceeded. It does not seem advisable to include such " maximum wheel-loads recommended " in our conclusions, as they would tend to limit the development of the power of the locomotives even more than many of the other difficulties of narrow-gauge lines, such as the curves and gradients, and therefore we propose the

following wording : " An axle-load of 10 tons (9·8 English tons) is recommended for lines having a gauge of 1 metre (3 ft. 3 3/8 in.); it is advisable, particularly on lines with steep gradients and on lines with sharp curves, to have as heavy axle-loads as possible."

B. — *Conclusions as regards locomotives.*

1. We have dealt in detail with the question of the power of the locomotives when considering the different types of locomotives; in order to obtain the increased power required for operating a given traffic, the following measures are to be recommended :

a) Increasing the working pressure to 14 atmospheres;

b) Superheating the steam to 300° C. (572° Fahr.);

c) Compounding.

One or more of these measures can be applied simultaneously, according to the circumstances of each case.

2° The increase of the adhesive weight beyond the figure which is determined by the maximum wheelbases for given minimum radii, by the admissible axle-loads and the maximum admissible loads per metre of track, is in the case of lines with steep gradients just as important a question as the increase of power.

Grz. recommends in paragraphs 50 and 78 :

Locomotives and rolling stock which are to be used on lines where the under-mentioned curves frequently occur on the open line, should have rigid wheelbases not exceeding :

Curves having a radius, in metres (in chains) of

25, 40, 50, 75, 100, 125, 150, 180, 210, etc.
(1 1/4), (2), (2 1/2), (3 3/4), (5), (6 1/4), (7 1/2), (9), (10 1/2), etc..

Rigid wheelbase of locomotive, in metres

1·1, 1·5, 1·6, 2·0, 2·3, 2·6, 2·9, 3·2, 3·5, etc.
(3' 7 5/16"), (4' 11"), (5' 3"), (6' 6 3/4"), (7' 6 9/16"), (8' 6 3/8"), (9' 6 3/16"), (10' 6"), (11' 5 13/16"), etc.

Rigid wheelbase of carriages, in metres

1·4, 1·8, 2·0, 2·5, 2·9, 3·3, 3·6, 3·9, 4·3, etc.
(4' 7 1/8"), (5' 10 7/8"), (6' 6 3/4"), (8' 2 7/16"), (9' 6 3/16"), (10' 10"), 11' 9 3/4"), (12' 9 9/16"), (14' 1 5/16"), etc.

As regards the first, paragraph 51 states :

As regards locomotives with wheelbases exceeding the limits specified in paragraph 50, it is recommended to use bogies or radially-adjustable axles.

As regards carriages, the following is added to the other prescriptions :

The security of the traffic is not endangered, if the rigid wheelbases are a little larger,

and it recommended,

in the case of carriages with several axles, that there should be allowed a corresponding extra amount of lateral play.

As far as can be gathered from the information received in answer to our list of questions, the maximum wheelbases re-

commended by the German *Verein* for locomotives have been exceeded in a rather considerable number of cases; on the other hand (excluding some unexplained cases, very few in number) the wheelbases specified were not exceeded without having at least one or two of the coupled axles radially adjustable, or having one or two pairs of the coupled wheels made without flanges.

Accordingly when the wheelbase dimensions given above are exceeded, it is in the first place advisable to use adjustable coupled axles, and if this does not suffice, the use of special motor bogies is then to be recommended.

SECTION II.

First supplementary question.

Is it advisable to protect the wheels and the moving parts by a metal cover?

---

1. — General considerations.

Twenty-eight administrations, who are enumerated in appendix II, part 2, have sent answers to this question; twelve of them limit themselves to the statement that they do not use such metal covers, although part of their lines also use public highways; sixteen of them make more or less detailed statements as to their views on this point; these are given in appendix II, part 3.

2. — The use of covers.

Comparing the answers as to the use of streets by the railways, and as to the use of covers, we obtain the following information :

Nine administrations use devices, either on some of their locomotives, or in some cases on all the locomotives of a given line, to protect the mechanism against dust; in the case of one locomotive type, the gear-wheel drive is enclosed in a dust-proof case so that it is completely protected against the action of any foreign bodies.

Seven of these nine administrations state that they also use streets; one gives no particulars, and one states that the whole of its line has its own road-bed.

Five administrations use no such protective coverings, although three of them have lines which use streets. Adding these to the twelve administrations previously mentioned, we find that there are altogether seventeen administrations not using any such protective coverings. Two of these administrations did use such covers formerly, but have removed them. This shows that the large majority of the administrations operating narrow-gauge lines, although many of them use streets, do not use such protective coverings.

3. — Results obtained in practice.

As regards results obtained in practice, the two administrations who formerly

used coverings but subsequently removed them, and one administration who still uses them, express the opinion that these coverings are unnecessary and make it more difficult to look after the locomotives.

Five administrations draw attention to the saving of the mechanism by the reduction of the wear; two of them however only expect real success if the whole is enclosed in a casing which is nearly dust-proof; this, apart from the closed gear-cases, can only be properly done in the case of outside frames, and one of the administrations expresses the opinion that a protective covering which is not really dust-tight is injurious rather than advantageous.

One administration thinks coverings are advisable in order to prevent the scaring of draft animals and to reduce damage in cases of collision or of grazing vehicles and persons, both for the latter and for the engine, while two administrations express the opposite opinion.

4. — Summary.

The chief question, whether the use of protective coverings seems necessary, and under what conditions it is to be recommended, or whether it appears to be superfluous, has been answered in many different ways, as was only to be expected from the treatment of the previous questions. The proportion of answers for and against is as follows :

Seven administrations consider protective coverings for the mechanism to be unnecessary, including firstly two administrations who formerly used such coverings and removed them, and one administration who is still using them; one of them states that the usual design is unsatisfactory, because it is not dust-proof; these three administrations have parts of their lines on streets; and secondly four administrations which do not use such coverings.

The same number, seven administrations, recommend protective coverings or consider their use desirable; six of them have used such coverings and one has not; two of these lines do not use the streets but have everywhere a road-bed of their own. One of them uses such coverings in order to economize in lubricating material and in the maintenance of the mechanism, as otherwise the dust which is raised would have a deleterious influence.

5. — Conclusions.

These contrary opinions are doubtless fully due, not only to the different importance attached to the advantages and disadvantages of such covers, but chiefly to the different conditions under which the traffic is operated. Not only has the quantity of dust to be considered in each individual case, but also its physical properties, particularly the hardness and the size and shape of its particles.

Those conditions make it impossible to give a general answer to the question; it will only be possible to give an answer in each individual case after the existing conditions have been considered.

The statements made enable the following general conclusion to be drawn : Protecting the wheels and the moving parts of the mechanism has as chief object the protection of the rubbing surfaces against foreign bodies, especially dust.

As secondary objects we may consider the fact that such locomotives scare animals, whether used for driving or for riding, less, and that in cases of collision or of grazing vehicles and persons, less damage is done. The coverings however make it more difficult to look after the engine, particularly at roadside stations with short stops; and care should be taken, when designing the arrangement, to provide for the easy accessibility of the mechanism.

If the locomotives are exposed to very dusty conditions, and if the dust consists of hard particles, the use of protective coverings is to be recommended, and the coverings should as far as possible be dust-proof and enclose the whole mechanism.

SECTION III.

Second supplementary question.

Is it advisable to have a footplate at each end of the locomotive? What regulations are there on the subject?

1. — General considerations.

Twenty-four administrations have sent answers to the list of questions on this subject, and nineteen have stated that their locomotives are only equipped with one footplate.

Thirteen of them have expressed no opinion as to the advisability of such an equipment, while six others consider it unnecessary, considering their traffic conditions; one administration considers it inadvisable. Thus there are five administrations left who have given an answer in the affirmative.

2. — Description of the designs.

A. — *With passage way round the locomotive.*

The Bavarian State Railway uses tank locomotive with two cabs, which are connected by a passage way round the locomotive; at each end there is a gangway by which the carriages can be reached.

The locomotive can only be driven from the one end, next the fire-box.

As it is possible to pass from the train to the locomotive while the train is in motion, the locomotive crew consists of one driver only. This naturally reduces the cost of traction, as the cost of a fireman is saved, and hence is worth special attention in connexion with narrow-gauge working.

B. — *Raised cab.*

The Arad-Csnad Railway has special tractors which it uses on its narrow-gauge lines.

These are distinguished by having a raised cab in the middle of the vehicle, from which an unobstructed view can be obtained in every direction.

The question of how a cab should be

arranged, to enable the driver to obtain as unobstructed a view as possible over the track and the adjoining parts, is no doubt solved in this case in the best possible way. This solution is however only available in cases where there is no ordinary locomotive or other boiler of large capacity, but only a steam generator without or with only a very small water-space. The expensive fuel required for such a boiler will however in many cases prove an obstacle te the extension of this system.

C. — *Two driver's cabs.*

The Belgian National Suburban Railway Company and the Aisne Department Railway use on street lines locomotives which have a cab at each end; both the regulator and the cut-off can be operated from each of the cabs. This arrangement enables the driver to have an unobstructed view over his track and over any streets joining the one on which the track is laid. The object aimed at is attained without undue multiplication of parts. On one type gangway, connections are provided, making it possible to pass from the train to the locomotive; in the other type, this is not the case. The turning of the locomotives, and the turntables necessary for this purpose, are saved in those cases in which the street lines pass through streets in which there is so much traffic that a cab which is at the back or in the middle can no longer be considered sufficiently safe. The cost of constructing and of maintaining the turntables is saved in this way, and the cost of working is reduced because the time required for turning at the end of the journey is saved. These administrations state this arrangement is to be recommended under these particular conditions.

D. — *Driver's cab on the carriages.*

The Great Western Railway (England) has introduced a peculiar design, which strictly speaking does not fall within the scope of this question, but which nevertheless has a similar object in view. It is intended for use on a standard-gauge line having its own road-bed, but can be also applied as it is to a narrow-gauge line, and hence is noticed here. A complete train consisting of two carriages and a tank locomotive is coupled up permanently so as to be able to run in either direction; the locomotive is placed between the two carriages. Each of these carriages has a cab at one end, the two cabs being at the head and at the tail of the train. The regulator can be operated from either cab by means of a mechanical rod and lever transmission. The driver is in that cab which is at the head of the train, the fireman is on the locomotive. It is not possible to pass from the carriage to the locomotive while the train is running; the employees on the train communicate by means of whistle and bell signals.

This arrangement makes it possible for the driver to have a clear view over the track and makes it unnecessary to shift the locomotive to the head of the train; it seems very suitable in the case of a shuttle service on a short section of line, where the direction of running is frequently reversed. Firstly, the time is saved, which would otherwise be required for shunting operations, and secondly the station line which would have to be kept clear for

these shunting operations, can be utilized for other purposes.

3. — Conclusions.

1° In the case of railways which use streets where there are many crossings and much traffic, it seems advisable to arrange matters in such a way that the driver not only has a good view from his locomotive over his track, but that he also can obtain as soon as possible a good view of any streets joining from either side. Leaving any turning of the locomotive at the terminus out of consideration, this object can be attained either by having a cab at each end of the locomotive, together with the necessary equipment for operating the regulator and the cut-off and for giving signals, or, if the locomotive is short, by having a raised cab from which it is possible to obtain an unobstructed view in any direction,

2° If the locomotive crew is to consist of one man only, it must be possible to pass from the carriages to the locomotive while the train is running; in the case of tank locomotives, this can be attained by having two footplates with gangway connexions. Only one of the footplates need be equipped with gear for driving the locomotive;

3° In the case of a shuttle service with a train of two carriages, the locomotive can be placed in the middle, if at least the regulator can be operated from the cabs at each end of the train.

CONCLUSIONS.

The consideration of the information given about existing locomotives and the examination of the relation between their chief properties and the character of the line, and the strength of the road and the roadbed lead to the following conclusions.

SECTION I.

Locomotives suited to the character of the line and of the traffic on narrow-gauge railways.

A. — *The design of new narrow-gauge lines which are to be operated with steam locomotives, are to be used for public traffic, and have to deal with a considerable amount of passenger or goods traffic.*

1° In all the cases in which the selection of the gauge of a new line is not decided in advance by its immediate junction with another line or by some other administrative connection with an existing narrow-gauge system, a gauge of 1 metre (3 ft. $3^3/_8$ in.) is considered the best. A smaller gauge than 600 millimetres (1 ft. 11 $^5/_8$ in.), and the selection of a new gauge which does not yet exist, are not to be recommended;

2° In the case of adhesion lines, whose locomotives work without any artificial increase of friction, it appears as a rule advisable not to have steeper gradients than 40 per mil;

3° It is recommended as a rule not to have curves with a radius of less than 40 metres (2 chains), if the vehicles are not specially designed for sharper curves. It is desirable to have the straights between the superelevation gradients of reverse curves, which are not equipped with guard rails, not shorter than the greatest existing distance between the bogies of a vehicle;

4° If a busy traffic has to be dealt with, it appears advisable to build the road and road-bed of a line having a gauge of 1 metre (3 ft. 3 3/8 in.), of such a strength that it can stand an axle-load of 10 tons (9·84 English tons); it is recommended, particularly in the case of lines with steep gradients and sharp curves, to provide for greater axle-loads.

B. — *As regards the design of new locomotives.*

1° The following may be recommended in order to increase the power of locomotives :

a) The use of a working pressure of up to 14 atmospheres;

b) Superheating the steam to 300° C. (572° Fahr.);

c) Compounding.

2° On lines on which the following curves frequently occur on the open line, no greater rigid wheelbases should be used than those given in the following table :

Radius of curve, in metres (in chains) :
25, 40, 50, 75, 100, 125, 150, 180 (1 1/4, 2, 2 1/2, 3 3/4, 5, 6 1/4, 7 1/2, 9).

Rigid wheelbase, in metres :
1·4, 1·8, 2·0, 2 5, 2·9, 3·3, 3·6, 3·9 (4' 7 1/8", 5' 10 7/8", 6' 6 3/4", 8' 2 7/16", 9' 6 3/16", 10' 10", 11' 9 3/4", 12' 9 9/16").

If the adhesive weight necessary can not be obtained inside the limits set by these wheelbases and the admissible maximum axle-loads, then, according to the excess required, the following arrangements can be recommended :

a) Lateral play;

b) Not having flanges on some of the pairs of coupled wheels; if these measures do not suffice, then;

c) Having some of the coupled axles radially adjustable; and finally

d) The use of one or two motor bogies movable relatively to the main frame, with mechanical transmission from one main steam engine or each with a separate steam engine.

SECTION II

Is it advisable to protect the wheels and the moving parts by a metal cover?

1° Locomotives which are liable to suffer from an unusual amount of dust, can have their moving parts protected by a covering, which is to enclose, as far as

possible, all the moving parts, and is to be as dust-proof as possible. Doors are to be provided in this covering so as to make the moving parts as accessible as possible;

2° Such coverings may also help to some extent to prevent the scaring of draft animals and to reduce damage in cases of collision with other vehicles, animals and persons.

SECTION III.

Is it advisable to have a footplate at each end of the locomotive?

1° In the case of lines which use streets in thickly-populated towns with much traffic, it is advisable to arrange matters so that the driver can in good time obtain an unobstructed view of any side streets crossing the line.

If it is not possible always to turn the locomotives so as to be head on, it is advisable to have a cab at each end of the locomotive; it must be possible to operate the regulator and the cut-off from each cab, and to give the necessary signals.

Tractors with a raised cab, from which an unobstructed view a can be obtained in every direction, satisfy this requirement without any need for turning them;

2° If the locomotive crew is to consist of one man only, it must be possible to pass from the train to the locomotive while running; this can be effected in the case of tank locomotives by having two footplates with gangway connexions. Only one of the footplates need be equipped for driving;

3° In the case of a shuttle service with a train of two carriages running on its own road-bed the locomotive can be placed in the middle, if it is possible to operate at least the regulator and the brakes from the carriage-cabs at the ends of the train.

APPENDIX I.

1. — Detailed list of questions relating to question XIX.

QUESTION 1. — *Particulars of the track.*

a) Gauge?

b) Smallest radius of curves: on the open line at switches?

c) Shortest straight between reserve curves:
Length of straight?
Radii?

d) Steepest gradient considered per mil, length?

QUESTION 2. — *Construction of locomotives for adhesion lines operated by steam; if possible, supply sketch of typical example, on a scale of 1 : 50, showing chief dimensions.*

a) Year of purchase?

b) Name of works, where locomotive was built?

c) Number of locomotives, of the different types?

d) Arrangement of axles:
Carrying axles, number?
— wheels, diameter?
— — wheel-load?
— — play, radial?
— — play, lateral?
— — used together in a truck?
Driving axles and coupled axled, number?
Diameter of wheels (D)?
Axle-load, in working order?
Lateral play?
Coupled up to form several driving sets?
Total length of locomotives over buffers?
Total wheelbase?
Rigid wheelbase?
Total weight in working order?
Adhesive weight?

e) *Arrangement of boiler.* — A sketch is desirable in the case of unusual constructions:
Heating surface of fire-box?
— — smoke-tubes?
— — superheater?
— — total?
Grate area?
System of smoke consumption?
Working pressure (p)?
Temperature of steam?

f) *Engine:*
Twin working?
Compound working-system?
Number of cylinders high pressure?
— — low pressure?
Diameter (d_h) high pressure?
— (d_n) low pressure?
Stroke?
System of valve gear?
Type of slide valve?
Theoretical tractive effort in the case of twin working $\frac{p \cdot d^2 \cdot l}{D}$?
of compound working, 2 cylinders $0{\cdot}75\frac{p \cdot d_h^2 \cdot l}{D}$?
of compound working, 4 cylinders $1{\cdot}5\frac{p \cdot d_h^2 \cdot l}{D}$?
Highest admissible speed?

g) *Brakes :*

Compressed-air system?
Vacuum-system?
Automatic action?
Number of axles braked?

h) *Steam heating?*

i) *Capacity :*

Of water tanks?
Of coal bunkers?

k) *separate tender?*

l) *Power of the locomotives :*

Fuel : source?
Fuel : designation of quality?
— lignite?
— brown coal?
— pit coal?
— anthracite?
— liquid fuel?
Its calorimetric value?
It evaporates on locomotives of the type this quantity of water?
With the fuel used there is a continuous output of horse power?
Normal weight of train, locomotive excluded :
On a gradient of per mil?
And at an absolute speed of miles per hour?

---

2. — List of the Administrations who sent answers to the list of questions relating to subject XIX, littera A.

A. — Railways with a gauge of 610 millimetres (2 feet).

GREAT BRITAIN AND IRELAND,

COLONIES IN SOUTH AFRICA.

1. — Central South African Railways.
2. — Natal Government Railways.

B. — Railways with a gauge of 750 millimetres (2 ft. 5 1/2 in.).

GERMANY.

1. — Saxon State Railway.
2. — Wurtemberg State Railway.

EGYPT.

3. — Fayoum Light Railways Company.

RUSSIA.

4. — First Secondary Railway Company of Russia.

C. — Railways with a gauge of 760 or 762 millim. (2 ft. 5 15/16 in. or 2 ft. 6 in.).

AUSTRIA AND HUNGARY.

a) AUSTRIA.

1. — Austrian State Railway.
2. — Bukovina Light Railway.
3. — Austrian Southern Railway.

b) HUNGARY.

4. — Arad-Csanad Railway.
5. — Kaschau-Oderberg Railway.

GREAT BRITAIN AND IRELAND.

EMPIRE OF INDIA.

6. — Bengal-Nagpur Railway.
7. — Eastern Bengal State Railway.
8. — North Western State Railway.
9. — Bombay, Baroda and Central India Railway.

D. — Railways with a gauge of 785 millimetres (2 ft. $6\,^{29}/_{32}$ in).

GERMANY.

1. — Prussian-Hessian State Railway, Kattowitz Directorate.

E. — Railways with a gauge of 890 or 891 mill (2 ft. $11\,^{3}/_{64}$ in, or 2 ft. $11\,^{5}/_{64}$ in.).

SWEDEN.

1. — Swedish State Railway.
2. — Stockholm Rimbo Railway.

F. — Railways with a gauge of 914 millimetres (3 feet).

UNITED STATES OF AMERICA.

1. — Baltimore and Ohio Railroad.
2. — Chicago, Burlington and Quincy Railroad.
3. — Pennsylvania Lines West of Pittsburgh.
4. — Southern Pacific Company.

G. — Railways with a gauge of 950 millimetres (3 ft. $1\,^{3}/_{8}$ in.).

ITALY.

1 — Italian State Railway.

H. — Railways with a gauge of 1 metre (3 ft. $3\,^{3}/_{8}$ in.).

GERMANY.

4. — Particulars of noteworthy types.

A. — Railways with a gauge of 610 millimetres (2 feet).

GREAT BRITAIN, COLONIES IN SOUTH AFRICA.

2. — *Natal Government Railways, Africa.*

Eastcourt-Weenen-Branch connects farming centres with the main lines.

Radius of sharpest curves on the open line : 61 metres (3·05 chains).

Radius of sharpest curves at switches : 64 metres (3·2 chains).

Shortest straight between reverse curves : 12 metres (13·1 yards).

Steepest gradient considered : 30 per mil with a corresponding reduction on curves

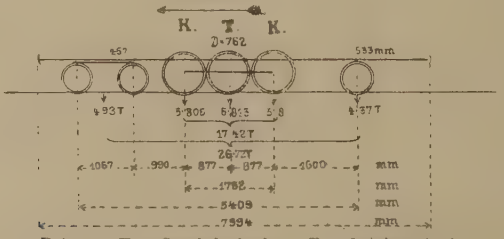
Year of purchase of locomotive : 1907.

Tank locomotive supplied by Hawthorn Leslie Co., Limited, Newcastle-on-Tyne (fig. 1).

Number : 6.

Adjustability of axles : lateral play of bogie, 76 millimetres (3 inches) ; of bissel truck, 102 millimetres (4 inches).

Arrangement of axles.



Reference : K. = Coupled wheels. — T. = Driving wheels.

Heating surface :

Fire-box. . .	3·7	sq. metres	(39·8 sq. feet).
Smoke-tubes.	58·9	—	(634·8 —).
Total. . .	62·6	sq. metres	(673·8 sq. feet).

Grate area : 1·02 sq. metres (11 sq. feet).

Working pressure : $p = 11{\cdot}6$ atmospheres.

Working : Twin-working.

Dimensions of cylinders :

$d \times l = 292 \times 381$ millim. ($11\ ^1/_2'' \times 1'\ 3''$).

System of valve gear : Walschaerts, with flat side valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 9{,}400$ kilog. (20,723 lb.).

Highest admissible speed : 24 1 kilometres (15 miles) per hour.

System of brakes steam and hand brake : Acting on three pairs of wheels.

Steam heating : none.

Capacity for coal, 1·2 cubic metres (42·3 cubic feet) ; water, 3·6 cubic metres (792 English gallons).

When using bituminous coal of round Natal, train weighing 70 tons gross (68·9 English tons), is hauled up a gradient of 30 per mil at a speed of 14·5 kilometres (9 miles) per hour.

B. — Railways with a gauge of millimetres (2 ft. $5\ ^1/_2$ in.).

GERMANY.

1. — *Saxon State Railway.*

Radius of sharpest curves on the open line : 50 metres ($2\ ^1/_2$ chains).

Radius of sharpest curves at switches : 43 metres (2 15 chains).

Shortest straight between reverse curves : 10 metres (10·9 yards).

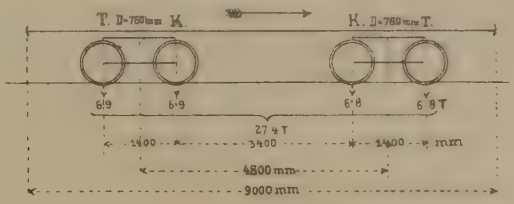
Steepest gradient considered : 40 per mil.

Year of purchase of locomotive : 1892 to 1908.

a) Tank locomotive supplied by the " Sächsische Maschinenfabrik " formerly R. Hartmann, Chemnitz in Saxony (fig. 2).

Number : 45

Arrangement of axles.



Adjustability of axles : Two combined in each bogie.

Heating surface :

Fire-box . . .	4·10 sq. metres	(44·13 sq. feet).
Smoke-tubes.	45·74	—	(492·35 —).
Total . . .	49·84 sq. metres	(536·48 sq. feet).

Grate area : 0·97 sq. metre (10·4 sq. feet).

Working pressure : p = 12 to 14 atmospheres.

Compound working : Meyer System.

Dimensions of cylinders (4) :

$d \times l$ { 2 × 240 × 380 mill. (9 7/16" × 1' 3").
2 × 370 × 380 — (1' 2 9/16" × 1' 3").

System of valve gear : Heusinger with flat side and Trick port valve.

Theoretical tractive effort according to the formula $1{\cdot}5 \frac{p \cdot d_h^2 \cdot l}{D}$ = 5,148 kilog. (11,349 lb.).

Highest admissible speed : 30 kilometres (18·6 miles) per hour.

Automatic brake acting on three pairs of wheels.

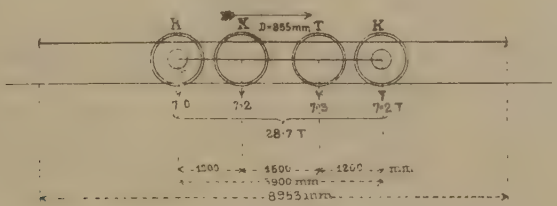
Capacity for coal, 1 cubic metre (35·3 cubic feet) ; water, 2·4 cubic metres (528 English gallons).

Year of purchase of locomotive : 1901.

b) Tank locomotive supplied by the " Sächsische Maschinenfabrik " formerly R. Hartmann Chemnitz in Saxony (fig. 3).

Number : 9.

Arrangement of axles.



Adjustability of axles : first and fourth coupled axle on the Klien-Lindner System.

Heating surface :

Fire-box. . .	4·22 sq metres	(45·42 sq. feet).
Smoke-tubes.	45·74	—	(492·35 —).
Total. . .	49·96 sq. metres	(537·77 sq. feet).

Grate area : 0·97 sq. metre (10·44 sq. feet).

Working pressure : p = 14 atmospheres.

Compound working.

Dimensions of cylinders :

$d \times l$ { 340 × 430 mill. (1' 1 3/8" × 1' 5").
530 × 430 — (1' 8 7/8" × 1' 4 15/16").

System of valve gear : Heusinger with flat slide valves and Trick port valve.

Theoretical tractive effort according to the formula $0{\cdot}75\frac{p \cdot d_h^2 \cdot l}{D} = 6{,}105$ kilog. (13,459 lb.).

Highest admissible speed : 30 kilometres (18·6 miles per hour.

Brakes acting on two pairs of wheels.

Capacity for coal, 1·2 cubic metres (42·3 cubic feet); water, 2 4 cubic metres (528 English gallons).

2. — *Wurtemberg State Railway.*

Radius of sharpest curves on the open line : 100 metres (5 chains).

Radius of sharpest curves at switches : 50 metres (2 1/2 chains).

Shortest straight between reverse curves : 38 metres long (41·5 yards) between curves having radii of 500 and 300 metres (25 and 15 chains).

Strepest gradient considered, 25 per mil on a length of 1,800 metres (1,969 yards).

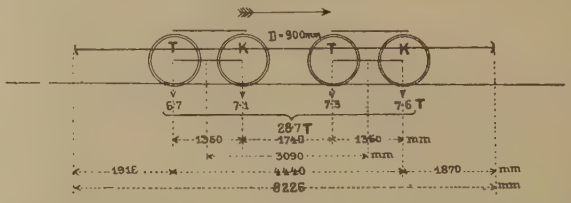
Years of purchase of locomotive 1899-1908.

Tank locomotive supplied by the "Maschinen Fabrik Esslingen" (fig. 4).

Number : 8.

Adjustability of axles : two combined in each bogie, on the Mallet-Rimrott system.

Arrangement of axles.



Heating surface :

Fire-box. . .	4·5	sq. metres	(48·4 sq. feet).
Smoke-tubes.	51·9	—	(558·6 —
Total . . .	56·4	sq. metres	(607·0 sq. feet).

Grate area : 0 98 sq. metre (10·54 sq. feet).

Working pressure : $p = 12$ atmospheres.

Compound-working.

Dimensions of cylinders (4) :

$d \times l$ { $2 \times 275 \times 450$ mill. ($10\,{}^{13}/_{16}' \times 1'\,5\,{}^{11}/_{16}''$).
{ $2 \times 420 \times 450$ — ($1'\,4\,{}^{9}/_{16}'' \times 1'\,5\,{}^{11}/_{16}''$).

System of valve year : Heusinger von Waldegg with Trick port valves.

Theoretical tractive effort according to the formula $1{\cdot}5\frac{p \cdot d_h^2 \cdot l}{D} = 6{,}800$ kil. (14,991 lb.).

Highest admissible speed : 30 kilometres (18·6 miles) per hour.

System of brakes : Westinghouse acting on two pairs of wheels.

Steam heating.

Capacity for coal, 1·2 cubic metres (42 3 cubic feet); water, 2·5 cubic metres (550 English gallons).

When using Saar and Ruhr coal mixed which evaporates 7·5 to 8 times its weight of water, 240 horse-power are developed and a train weighing 90 tons gross (88·6 English tons), is hauled up a gradient of 25 per mil at a speed of 20 kilometres (12·4 miles) per hour.

RUSSIA.

4. — *First secondary Railway Company of Russia.*

Radius of sharpest curves on the open line : 106·7 metres (5·33 chains).

Radius of sharpest curves at switches : 64 metres (3·2 chains).

Shortest straight between reverse curves : 22·4 metres (24·5 yards).

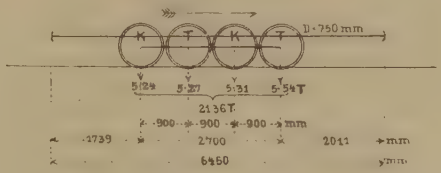
Steepest gradient considered : 15 per mil over a length of 853 metres (933 yards).

Year of purchase of locomotives : 1898, 1902 and 1908.

Locomotive with separate tender supplied by Kolomna Works.

Number : 91.

Arrangement of axles.



Adjustability of axles : 14 millimetres ($^9/_{16}$ inch) of lateral play.

Heating surface :

Fire-box. . .	6.0 sq. metres	(64·5 sq. feet).
Smoke-tubes.	49·6 —	(533·9 —).
Total. . .	55·6 sq. metres	(598·4 sq. feet).

Grate area : 1·15 sq. metres (12·37 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 355 \times 300$ millim. ($1' 2'' \times 11\ ^{13}/_{16}''$).

System of valve gear Heusinger.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}049$ kilog. (13,358 lb.).

Highest admissible speed : 32 kilometres (19·9 miles) per hour.

Steam heating : Screw breake.

Capacity for fuel = 5 cubic metres (177 cubic feet); water, 5·4 cubic metres (1,188 English gallons).

When using birch wood and pine wood 197 horse-power are developed and a train weighing 202 tons gross (198·8 English tons), is hauled up a gradient of 8 per mil at a speed of 21 kilometres (13·0 miles) per hour.

C. — Railways with a gauge of 760 or 762 millimetres (2 ft. 5 $^{29}/_{32}$ in. or 2 ft. 6 in.).

AUSTRIA AND HUNGARY.

Gauge : 760 millimetres (2 ft. 5 $^{29}/_{32}$ in.).

a) Austria.

1. — *Austrian State Railway.*

Radius of sharpest curves on the open line : 60 metres (3 chains).

Radius of sharpest curves at switches : 65 metres (3 $^1/_4$ chains).

Shortest straight between reverse curves : 7 metres (7·6 yards).

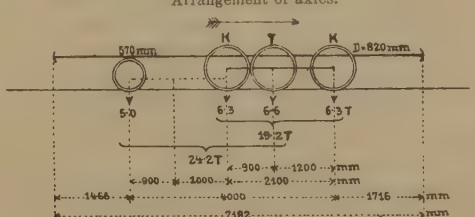
Steepest gradient considered : 32 per mil.

Year of purchase of locomotive : 1897 — 1908.

a) Tank locomotive supplied by Krauss & Co., Linz; Lokomotivfabrik, Wiener Neustadt; Maschinenfabrik der Staatseisenbahn-Gesellschaft; I Böhm-Mahr. Maschinen Fabrik (fig. 5).

Number : 41.

Arrangement of axles.



Adjustability of axles ; Bissel truck with lateral play of 35 millimetres (1 3/8 inches) of the last coupled axle, which has a play of 25 millimetres (1 inch) towards either side, effects the lateral displacement.

Heating surface :

Fire-box. . .	4·42 sq. metres	(47·57 sq. feet).
Smoke-tubes.	46·28 —	(498·17 —).
Total. . .	50·70 sq. metres	(545·74 sq. feet).

Grate area : 1 sq. metre (10·76 sq. feet).

Working pressure : $p = 12$ atmospheres.

Smoke consumer : Marek system.

Twin-working.

Dimensions of cylinders :

$d \times l = 290 \times 400$ millim. ($11\ 7/16'' \times 1'3\ 3/4''$).

System of valve gear : Heusinger von Waldegg with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 5{,}046$ kilog. (11,125 lb.).

Highest admissible speed : 35 kilometres (21·7 chains).

System of brakes vacuum automatic : Acting on two pairs of wheels.

Capacity for coal, 1·7 cubic metre (60 cubic feet); water, 3·2 cubic metres (704 English gallons).

When using Hinterholz coal which evaporates 5·2 times its weight of water 225 horse-power are developed and a train weighing 95 tons gross (93·5 English tons) is hauled up a gradient of 10 per mil at a speed of 35 kilometres (21·7 miles) per hour.

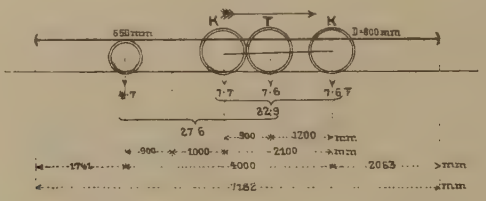
—

Year of purchase of locomotive : 1904.

b) Tank locomotive supplied by the Lokomotivfabrik Krauss & Co., Linz (fig. 6).

Number : 3.

Arrangement of axles.



Adjustability of axles : Bissel truck with lateral play of 35 millimetres (1 3/8 inches) towards either side, effects the lateral displacement of the last coupled axle, which has a play of 25 millimetres (1 inch).

Heating surface :

Fire-box. . .	4·6 sq. metres	(49 5 sq. feet).
Smoke-tubes.	57·8 —	(622·1 —).
Total. . .	62·4 sq. metres	(671·6 sq. feet).

Grate area : 1·03 sq. metre (11·08 sq. feet).

Working pressure : $p = 13$ atmospheres.

Compound working.

Dimensions of cylinders :

$d \times l = \frac{320}{500}$ mill. $\left(\frac{1'0\ 19/32''}{1'7\ 14/16''}\right) \times 400$ mill. ($1'3\ 3/4''$).

System of valve year : Heusinger-Waldegg with flat valves.

Theoretical tractive effort according to the for, mula $0.75 \frac{p \cdot d^2 \cdot l}{D} = 4{,}855$ kilog. (10,703 lb.).

Highest admissible speed : 35 kilometres (21.7 miles) per hour.

System of brakes vacuum automatic : Acting on two pairs of wheels.

Steam heating.

Capacity for coal, 1·7 cubic metres (60 cubic feet); water, 3·1 cubic metres (682 English gallons).

When using upper Silesian coal which evaporates 6·7 times its weight of water 273 horse-

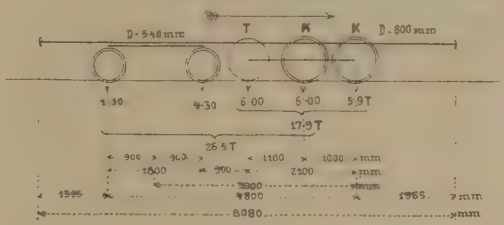
power are developed and a train weighing 115 tons gross (113·2 English tons), is hauled up a gradient of 10 per mil at a speed of 35 kilometres (21·7 miles) per hour.

Year of purchase of locomotive : 1896.

c) Tank locomotive supplied by Krauss & Co., Linz (fig. 7).

Number : 3.

Arrangement of axles



Adjustability of axles : carrying axles in bogie, driving without flanges.

Heating surface :

Fire-box . .	4·30 sq. metres	(46 28 sq. feet).
Smoke-tubes	61·4 —	(660·92 —).
Total . .	65·70 sq. metres	(707.20 sq. feet).

Grate area : 1·03 square metres (11·08 sq. feet).

Working pressure : $p = 13$ atmospheres.

Compound-working.

Dimensions of cylinders :

$$d \times l = \frac{310}{450} \times 400 \text{ mill.} \left(\frac{1' \, 3\,{}^{3}/_{16}''}{1' \, 5\,{}^{11}/_{16}''} \times 1' \, 3\,{}^{3}/_{4}'' \right).$$

System of valve year : Heusinger von Waldegg, with flat valves.

Theoretical tractive effort according of the formula $0{\cdot}75 \frac{p' \cdot d^2 \cdot l}{D} = 4{,}685$ kilog. (10,328 lb.).

Highest admissible speed : 40 kilometres (24·8 miles) per hour.

System of brakes vacuum automatic : acting on two pairs of wheels.

Steam heating.

Capacity for coal, 1 cubic metre (35·3 cubic feet); water, 3 cubic metres (660 Engl. gallons).

When using Newcastle coal which evaporates 6·95 times its weight of water 284 horse-power are developed and a train weighing 100 tons gross (98·4 English tons), is hauled up a gradient of 10 per mil at a speed of 40 kilometres (24·8 miles) per hour.

—

2. — *Bukovina Local Railway.*

Name of line Czudin-Koszczuja.

Radius of sharpest curves on the spen line : 100 metres (5 chains).

Radius of sharpest curves at switches : 65 metres (3 ¼ chains).

Shortest straight between reverse curves : 100 metres (109 yards) between curves having a radius of 200 metres (10 chains).

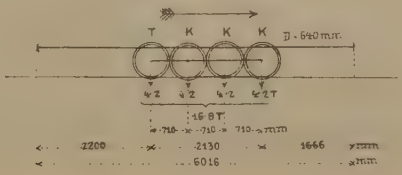
Steepest gradient considered : 17 per mil; length, 830 metres (908 yards).

Year of purchase of locomotive : 1908.

Tank locomotive supplied by Krauss & Co., Linz (fig. 8).

Number : 2.

Arrangement of axles.



Adjustability of axles : this two middle axles have a lateral play of 20 millimetres ($^{13}/_{16}$ inch).

Heating surface :

Fire-box . .	3·59 sq. metres	(38 64 sq. feet).
Smoke-tubes	26·95	—	(290·09 | — |).
Total . .	30·54 sq. metres	(328·73 sq feet).

Grate area : 0·706 sq. metre (7·599 sq. feet).

Working pressure : $p = 13$ atmospheres.

Compound-working.

Dimensions of cylindres :

$$d \times l = \frac{270}{410} \times 340 \text{ mill.} \left(\frac{10\ ^5/_8''}{1'\ 4\ ^5/_{32}''} \times 1'\ 1\ ^3/_8'' \right).$$

System of valve year : Heusinger von Waldegg, with flat valves.

Theoretical tractive effort according to the formula $0{\cdot}75 \frac{p \cdot d_h^2 \cdot l}{D} = 3{,}776$ kilog. (8,325 lb.).

Highest admissible speed : 25 kilometres (15·5 miles) per hour.

Screw brakes, acting on two pairs of wheels.

Steam heating.

Capacity for coal, 1·6 cubic metres (56·5 cubic feet) ; water, 2 cubic metres (440 English gallons).

When using upper Silesian coal, which evaporates 6·3 times its weight of water, a train weighing 100 tons gross (98·4 English tons), is hauled up a gradient of 17 per mil at a speed of 10 kilometres (6·2 miles) per hour.

—

3. — *Austrian Southern Railway, as managing administration.*

c) Styrian Country Railway. Kapfenberg Au-Seewiesen line.

Radius of sharpest curves on the open line : 80 metres (4 chains).

Radius of sharpest curves at switches : 65 metres (3 $^1/_4$ chains).

Shortest straight between reverse curves : 23·85 metres (26·08 yards) between curves having radii of 80 and 90 metres (4 and 4 $^1/_2$ chains).

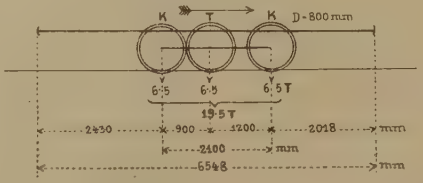
Steepest gradient considered : 25 per mil.

Year of purchase of locomotive : 1893.

Tank locomotive supplied by the Lokomotivfabrik Krauss & Co., Linz (fig. 9).

Number : 3.

Arrangement of axles.



Heating surface :

Fire-box. . .	3 sq. metres	(32·29 sq. feet).
Smoke-tubes.	37	—	(398·27 | — |).
Total. . .	40 sq. metres	(430·56 sq. feet).

Grate area : 0·77 square metre (8·28 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 290 \times 400$ millim. ($11\ ^7/_{16}'' \times 1'\ 3\ ^3/_4''$).

System of valve year : Heusinger von Waldegg, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 5{,}046$ kilog. (11,126 lb.).

Highest admissible speed : 35 kilometres (21·7 miles) per hour.

System of brakes vacuum : acting on three pairs of wheels.

Steam heating : none.

Capacity for coal, 1 cubic metre (35·3 cubic feet) ; water, 2·26 cubic metres (497·4 English gallons).

When using Ostrau coal 150 horse-power are developed and a train weighing 70 tons gross

(68·9 English tons), is hauled up a gradient of 25 per mil at a speed of 15·2 kilometres (9·4 miles) per hour.

—

e) Styrian country railway, Preding-Wieselsdorf and Pöltschach-Gonobitz lines.

Radius of sharpest curves on the open line : 60 metres (3 chains).

Radius of sharpest curves at switches : 65 metres (3 1/4 chains).

Shortest straight between reverse curves : 21 metres (22·9 yards).

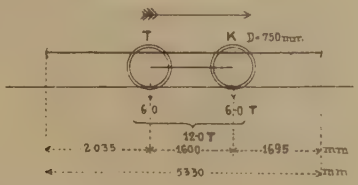
Steepest gradient considered : 16 per mil.

Year of purchase of locomotive : 1892.

Tank locomotive supplied by the Lokomotivfabrik Krauss & Co., Linz (fig. 10).

Number : 2.

Arrangement of axles.



Heating surface :

Fire-box. . .	2·36 sq. metres	(25·40 sq. feet).
Smoke-tubes.	21·35 —	(229·81 —
Total. . . .	23·71 sq. metres	(255·21 sq. feet).

Grate area : 0·51 sq metre (5·49 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 225 \times 350$ millim. (8 7/8″ × 1′ 1 3/4″).

System of valve year : Stephenson, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 2{,}835$ kilog. (6,250 lb.).

Highest admissible speed : 25 kilometres (15·5 miles) per hour.

System of brakes vacuum : acting on two pairs of wheels.

Steam heating.

Capacity for coal : 0·7 cubic metre (24·7 cubic feet); water, 1·15 cubic metre (253·1 English gallons).

When using lignite coal 70 horse-power are developed and a train weighing 80 tons gross (78 7 English tons), is hauled up a gradient of 16 per mil at a speed of 12·3 kilometres (7·6 miles) per hour.

—

b) Hungary.

4. — *Arad-Csanad Railways.*

First Lower Hungarian Agricultural line.

Radius of sharpest curves on the open line : 60 metres (3 chains).

Radius of sharpest curves at switches : 52 metres (2·6 chains).

Shortest straight between reverse curves : 10 metres (10·9 yards).

Steepest gradient considered : 10 per mil.

Tractors.

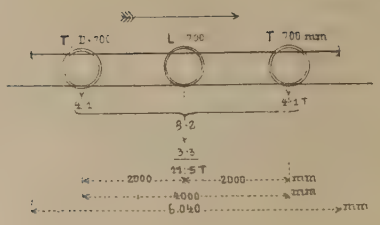
Year of purchase of locomotive : 1904.

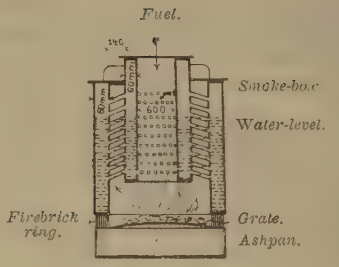
Tank locomotive supplied by the locomotive works of the Hungarian state railway.

Number : 2.

Adjustability of axles : free flexible axle.

Arrangement of axles.





Heating surface :

Water-tubes.	2 × 6·4 sq. met.	(2 × 68·9 sq. ft.).
Superheater.	2 × 2·2 —	(2 × 23·7 —).
Total. . .	17·2 sq. metres	(185·2 sq feet).

Grate area : 2 × 1·1 sq. met. (11·8 sq. feet).

Working pressure : $p = 18$ to 25 atmospheres.

Compound-working in four cylinders.

Dimensions of cylinders :

$$d \times l = \frac{2 \times 116}{2 \times 170} \times 140 \text{ millimetres}$$

$$\left(\frac{2 \times 4\ ^{9}/_{16} \text{ inches}}{2 \times 6\ ^{11}/_{16} \text{ inches}} \times 5\ ^{1}/_{2} \text{ inches}\right).$$

Theoretical tractive effort according to the formula $1{\cdot}5 \frac{p \cdot d_h^2 \cdot l}{D} = 1{,}010$ kilog. (2,227 lb.).

Highest admissible speed : 35 kilometres (21·7 miles) per hour.

Hand brake : acting on two pairs of wheels.

Steam heating.

Capacity for coal, 2 cubic metres (70·6 cubic feet); water, 2 cubic metres (440 English gallons).

When using charcoal or coke, which evaporates 6·5 times its weight of water 75 horse-power are developed and a train weighing 80 tons gross (78·7 English tons), is hauled up a gradient of 10 per mil at a speed of 15 kilometres (9·3 miles) per hour.

—

5. — *Kaschau-Oderberg Railway.*

Rózsahegy-Korytinca.

Radius of sharpest curves on the open line : 65 metres (3 ¼ chains).

Radius of sharpest curves at switches : 60 metres (3 chains).

Shortest straight between reverse curves : 25 metres (27 yards).

Steepest gradient considered : 22·5 per mil.

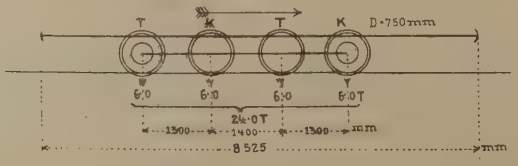
Year of purchase of locomotive : 1908.

Tank locomotive supplied by the locomotive works of the Hungarian State Railway, Budapest.

Number : 3.

Adjustability of axles on the Klien-Lindner system.

Arrangement of axles.



Heating surface :

Fire-box. . .	4·38 sq. metres	(47·14 sq. feet).
Smoke-tubes.	44·23 —	(476·10 —).
Total. . .	48·61 sq. metres	(523·24 sq. feet).

Grate area : 0·9 sq. metre (9·68 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 340 \times 350$ mill. (1′ 1 3/8″ × 1′ 1 1/16″).

System of valve gear : Stephenson with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}470$ kilog. (14,264 lb.).

Highest admissible speed : 25 kilometres (15·5 miles) per hour.

System of brakes screw brake: acting on two pairs of wheels.

Steam heating.

Capacity for coal, 1·32 cubic metres (46·62 cubic feet); water, 2·30 cubic metres (506·2 English gallons).

GREAT BRITAIN, COLONIES IN INDIA.

(Gauge : 762 millimetres [2 ft. 6 in.]).

6 — *Bengal Nagpur Railway.*

Radius of sharpest curves on the open line : 125 metres (6 1/4 chains) as a rule but there are two curves with 117 metres (5·85 chains).

Radius of sharpest curves at switches : 86 metres (4·3 chains); but all new ones have radii of 110 metres (5 1/2 chains).

Shortest straight between reverse curves : 14 metres (15·3 yards), between curves with radii of 436 and 125 metres (21·8 and 6 1/4 chains).

Steepest gradient considered 12·5 per mil.

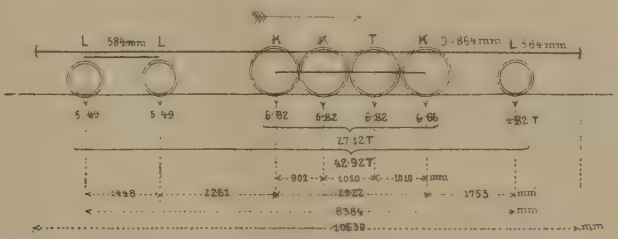
Year of purchase of locomotive : 1905.

a) Tank locomotive for mixed traffic supplied by North British Locomotive Company.

Number : 16.

Adjustability of axles : radial play 2 1/4°, lateral play 1/8 inch, two axles together in a bogie.

Arrangement of axles.



Heating surface :

Fire-box. . .	6·21 sq. metres	(66·84 sq. feet).
Smoke-tubes.	77·74 —	(836·81 —).
Total. . .	83·95 sq. metres	(903·65 sq. feet).

Grate area : 1·5 sq. metre (16·14 sq. feet).

Working pressure : $p = 11.3$ atmospheres.

Twin working in 2.

Dimensions of cylinders :

$d \times l = 368 \times 457$ mill. (1′ 2 1/2″ × 1′ 6″).

System of valve gear : Walschaerts with balanced D valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 8{,}520$ kilog. (18,783 lb.).

Highest admissible speed : 24 kilometres (14.9 miles) per hour.

System of brakes steam for locomotive and automatic vacuum for train : acting on three pairs of wheels.

Capacity for coal, 3 cubic metres (105·9 cubic feet); water, 6·3 cubic metres (1,386·6 English gallons).

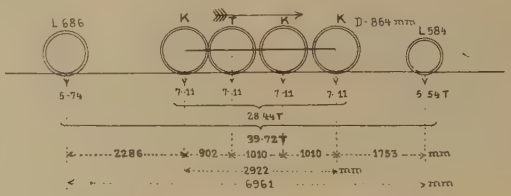
Pench Valley coal is used.

Year of purchase of locomotive : 1907-1909.

b) Locomotive with separate tender for goods trains supplied by North British Locomotive Co.

Number : 30.

Arrangement of axles.



Adjustability of axles : two Bissel axles, radial play 2 $^1/_4$°.

Heating surface :

Fire-box . .	7·33 sq. metres	(78·90 sq. feet).
Smoke-tubes	107·0 —	(1,151·78 —).
Total . .	114·33 sq. metres	(1,230·68 sq. feet).

Grate area : 1·91 sq. metres (20·55 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working with two cylinders.

Dimensions of cylinders :

$d \times l = 368 \times 457$ mill. ($1' 2\ ^1/_2'' \times 1' 6''$).

System of valve gear : Walschaerts, with balanced D valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 9{,}090$ kilog. (20,040 lb.).

Highest admissible speed : 24 kilometres (14·9 miles) per hour.

System of brakes steam brake for locomotive and tender : acting on three pairs of wheels of the locomotive and three pairs of wheels of the tender, automatic vacuum brake for train.

Steam heating : none.

Capacity for coal, 3 cubic metres (105·9 cubic feet) ; water, 7·7 cubic metres (1,694·7 English gallons).

Pench Valley coal is used.

—

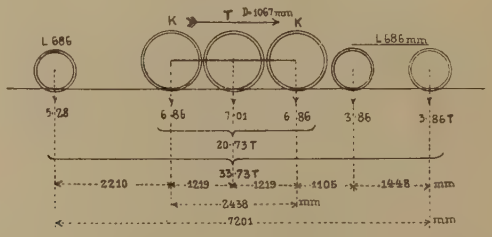
Year of purchase of locomotive : 1906-1909.

c) Locomotive with separate tender for passenger trains supplied by North British Locomotive Co.

Number : 20.

Adjustability of axles : radial play 1 $^1/_2$°, lateral play $^1/_8$ inch, two axles together in a bogie.

Arrangement of axles.



Heating surface :

Fire-box . .	6·12 sq. metres	(65·87 sq. feet).
Smoke-tubes	90·39 —	(972·98 —).
Total. . .	96·51 sq. metres	(1,038 85 sq. feet).

Grate area : 1·62 sq. metres (17·43 sq. feet).

Working pressure : $p = 11{\cdot}3$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 368 \times 457$ mill. ($1' 2\,^1/_2'' \times 1' 6''$).

System of valve year : Walschaerts, with balanced D valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}890$ kilog. (15,190 lb.).

Highest admissible speed : 24 kilometres (14·9 miles) per hour.

System of brakes steam brake for locomotive and tender : acting on three pairs of wheels of the locomotive and three pairs of wheels of the tender, automatic vacuum brake for the train.

Steam heating : none.

Capacity for coal, 3 cubic metres (105·9 cubic feet); water, 7·7 cubic metres (1,694·7 English gallons).

Pench Valley coal is used.

8. — *North Western State Railway.*

Kohat-Thal Railway & Nowshera-Dargai Railway.

Radius of sharpest curves on the spen line : 73 and 84 metres (3·65 and 4·2 chains).

Radius of sharpest curves at switches : 111 metres (5·55 chains).

Shortest straight between reverse curves : 20 metres (21·9 yards).

Steepest gradient considered : 10 and 12 per mil.

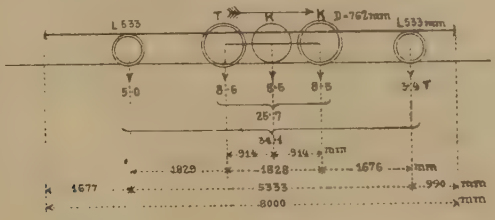
Year of purchase of locomotive : 1904.

Tank locomotive supplied by North British Locomotive Co., Limited.

Number : 2.

Adjustability of axles : carrying wheels radially adjustable ; the middle has wheels without flanges.

Arrangement of axles.



Heating surface :

Fire-box. . .	5·9 sq. metres	(63·59 sq. feet).
Smoke-tubes.	63·7 —	(685·60 —).
Total. . .	69·6 sq. metres	(749·19 sq. feet).

Grate area : 1·32 sq. metres (14·21 sq. feet).

Working pressure : $p = 12{\cdot}7$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 356 \times 406$ millim. ($1' 2'' \times 1' 4''$).

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 8{,}550$ kilog. (18,850 lb.).

Highest admissible speed : 24·1 kilometres (15·0 miles) per hour.

System of brakes vacuum automatic : acting on three pairs of wheels.

Steam heating : none.

Capacity for coal, 1·9 cubic metres (67·1 cubic feet); water, 3·05 cubic metres (671·3 English gallons).

Pit coal is used, and a train weighing 80 tons (78·7 English tons) gross is hauled.

—

9. — *Bombay, Baroda and Central India Railway.*

Radius of sharpest curves on the open line : 152·4 metres (7·68 chains).

Radius of sharpest curves at switches : 91·4 metres (4·57 chains).

*

Shortest straight between reverse curves : 30·1 metres (32·9 yards) between curves having radii of 873 and 524 metres (43·65 and 26·2 chains).

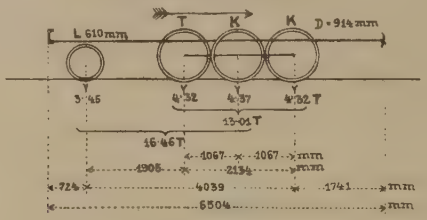
Steepest gradient considered : 6·66 per mil.

Year of purchase of locomotive : 1903.

Locomotive with separate tender supplied by Kitson & Co., Leeds (England).

Number 3 in use and several on order.

Arrangement of axles.



Adjustability of axles : carrying axle in pony truck, lateral play 76 millimetres (3 inches).

Heating surface :

Fire-box. . .	6·1 sq. metres	(65·66 sq. feet).
Smoke-tubes.	46·0 —	(495·15 —).
Total. . .	52·1 sq. metres	(560·81 sq. feet).

Grate area : 1·1 sq. metres (11·84 sq. feet).

Working pressure : $p = 11{\cdot}2$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 279 \times 381$ millim. ($11'' \times 1'\ 3''$).

System of valve gear : Walschaerts modified by Kitson, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D}$ = 3,640 kilog. (8,025 lb.).

Highest admissible speed : 32·2 kilometres (20·0 miles) per hour.

System of brakes steam and hand : acting on three pairs of wheels.

Steam heating : none.

Capacity for coal, 2·5 cubic metres (88·3 cubic feet); water, 4·5 cubic metres (990 English gallons).

When using pit coal which evaporates 6·49 times its weight of water train weighing 356 tons (349·6 English tons) gross on the flat is hauled at a speed of 24·6 kilometres (15·3 miles) per hour.

D. — Railways with a gauge of 785 millimetres (2 ft. 6 $^{29}/_{32}$ in.).

GERMANY.

1. — *Prussian State Railway, Kattowitz Directorate.*

Upper Silesian narrow-gauge lines.

Radius of sharpest curves on the open line : 40 metres (2 chains).

Radius of sharpest curves at switches : 35 metres (1 $^3/_4$ chains) where locomotives are used and 24 metres (1·2 chains) where they are not used.

Shortest straight between reverse curves : 10 metres (10·9 yards).

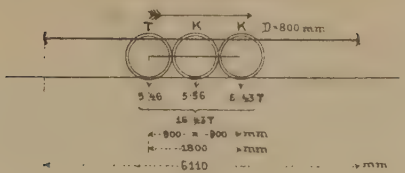
Steepest gradient considered : 40 per mil.

Year of purchase of locomotive : 1876 to 1880, 1884, 1888, 1890, 1891.

a) Tank locomotive supplied by Krauss in Munich and Hagans in Erfurt, of 2 very similar types; the more powerful is described.

Number : 39.

Arrangement of axles.



Heating surface :

Fire-box. . .	2·74 sq. metres	(29·94 sq. feet).
Smoke-tubes.	24 36	—	(262·22 —).
Total. . .	27·10 sq. metres	(292·16 sq. feet).

Grate area : 0·64 sq. metre (6·89 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 280 \times 400$ millim. ($11'' \times 1'\,3\,3/4''$).

System of valve year : Stephenson with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 4{,}704$ kilog. (10,370 lb.)

Highest admissible speed : 25 kilometres (15·5 miles) per hour.

Sytem of brakes screw brake : Acting on two pairs of wheels.

Steam heating : none.

Capacity for coal, 1·35 cubic metres (47·7 cubic feet); water, 1·6 cubic metres (352 English gallons).

When using Upper Silesian coal train weighing 130 tons (127·9 English tons) gross, is hauled up a gradient of 13 per mil at a speed of 10 kilometres (6·2 miles) per hour.

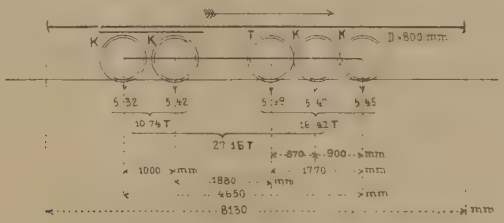
—

Year purchase of locomotive : 1898-1901.

b) Tank locomotive supplied by Hagans in Erfurt.

Number : 4.

Arrangement of axles.



Adjustability of axles : the coupled axles are in two motor bogies, on the Hagans system.

Heating surface :

Fire-box. . .	4·42 sq. metres	(47·58 sq. feet).
Smoke-tubes.	55·89	—	(601·61 —).
Total. . .	60 31 sq. metres	(649·19 sq. feet).

Grate area : 1·11 sq. metres (11·94 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 350 \times 400$ millim. ($1'1\,3/4'' \times 1'\,3\,3/4''$).

System of valve year : Heusinger with fla valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 7{,}350$ kilog. (16,204 lb.).

Highest admissible speed : 25 kilometres (15·5 miles) per hour.

System of brakes and brake : Acting on two pairs of wheels.

Steam heating : none.

Capacity for coal, 1·5 cubic metres (53 cubic

feet); water, 2·5 cubic metres (550 English gallons).

When using Upper Silesian coal train weighing 180 tons (177·2 English tons) gross, is hauled up a gradient of 13 per mil at a speed of 10 kilometres (6·2 miles) per hour.

—

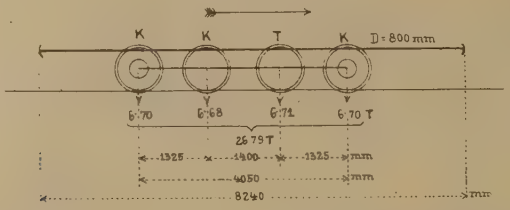
Year of purchase of locomotive : 1902.

c) Tank locomotive supplied by Hartmann, in Chemnitz.

Number : 2.

Adjustability of axles : First and fourth axle on the Klien-Lindner system. Middle axles fixed.

Arrangement of axles.



Heating surface :

Fire-box. . .	4·68	sq. metres	(50·37 sq. feet).
Smoke-tubes.	49·38	—	(531 54 —).
Total. . .	54·06	sq. metres	(581·91 sq. feet).

Grate area : 1·08 sq. metre (11.62 sq. feet).

Working pressure : $p = 12{\cdot}5$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 340 \times 400$ mill. ($1'\ 1\ ^3/_8'' \times 1'\ 3\ ^3/_4''$).

System of valve gear : Heusinger, with flat valves.

Theoretical tractive effort according of the formula $\frac{p \cdot d^2 \cdot l}{D} = 7{,}225$ kilog. (15,928 lb.)

Highest admissible speed : 25 kilometres (15.5 miles) per hour.

System of brakes hand brake automatic : Acting on two pairs of wheels.

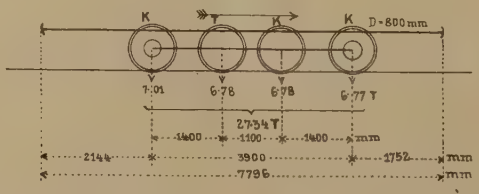
Steam heating : none.

Capacity for coal, 1·5 cubic metres (53 cubic feet); water, 2·5 cubic metres (550 English gallons).

When using upper Silesian coal, a train weighing 180 tons (177·1 English tons) gross, is hauled up a gradient of 13 per mil at a speed of 10 kilometres (6.2 miles) per hour.

—

Arrangement of axles.



Year of purchase of locomotive : 1904, 1905 and 1907.

d) Tank locomotive supplied by Orenstein & Koppel, A. G. in Drewitz-Berlin (fig. 11).

Number : 10.

Adjustability of axles : first and fourth axle on the Klien-Lindner system; in addition the middle axles have a lateral play of 20 millimetres ($^{25}/_{32}$ inch).

Heating surface :

Fire-box. . .	3·70 sq. metres	(39·82 sq. feet).
Smoke-tubes.	49·09	—	(528·41 —).
Total. . .	52·79 sq. metres	(568·23 sq. feet).

Grate area : 1·0 sq. metre (10·76 sq. feet).

Working pressure : $p = 13$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 340 \times 400$ mill. ($1' 1\ 3/8'' \times 1' 3\ 3/4''$).

System of valve gear : Heusinger, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 7{,}514$ kilog. (16,565 lb.).

Highest admissible speed : 25 kilometres (15·5 miles) per hour.

System of brakes hand brake automatic : Acting on two pairs of wheels.

Steam heating : none.

Capacity for coal, 1·5 cubic metres (53 cubic feet); water, 2·5 cubic metres (550 English gallons).

When using upper Silesian coal, a train weighing 180 tons (177·1 English tons) gross, is hauled up a gradient of 13 per mil at a speed of 10 kilometres (6.2 miles) per hour.

E. — Railways with a gauge of 890 or 891 millimetres (2 ft. 11 3/64 in. or 2 ft. 11 5/64 in.)

SWEDEN.

---

1. — *Swedish State Railway.*

Stockholm-Rimbo.

Radius of sharpest curves on the open line : 200 metres (10 chains).

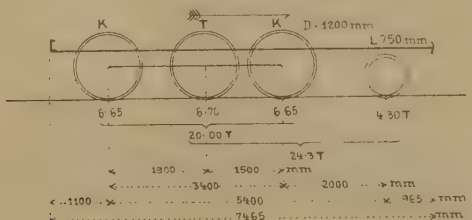
Radius of sharpest curves at switches : 125 metres (6 1/4 chains).

Year of purchase of locomotive : 1904 and 1906.

a) Tank locomotive supplied by « Vagn & Maskin Fabriks A. G. Fahlun » (fig. 12).

Number : 3.

Arrangement of axles.



Adjustability of axles : Bissel axle with lateral lay of 50 millimetres (2 inches) towards each side.

Heating surface :

Fire-box. . .	6·0 sq. metres	(64·58 sq. feet).
Smoke tubes.	54·5	—	(586·65 —).
Total. . .	60·5 sq. metres	(651·23 sq. feet).

Grate area : 0·9 sq. metre (9·68 sq. ft.)

Working pressure : $p = 12{\cdot}5$ atmospheres.

Compound working.

Dimensions of cylinders :

$d \times l = \frac{340}{510} \times 500$ mill. $\left(\frac{1'\,1\,3/8''}{1'\,8''} \times 1'\ 7\ 11/16''\right)$

System of valve gear : Heusinger, with flat valves.

Theoretical tractive effort according to the formula $0.75\ \frac{p \cdot d_h^2 \cdot l}{D} = 4{,}500$ kilog. (9,921 lb.).

Highest admissible speed : 60 kilometres (37·3 miles) per hour.

System of brakes New-York air brake automatic : acting on three pairs of wheels.

Capacity for coal, 2·0 cubic metres (70·6 cubic feet); water, 8·0 cubic metres (1,760 English gallons).

—

Stockholm-Rimbo and Dala-Ockelbo-Norrsundet.

Radius of sharpest curves on the open line : 148 metres (7·4 chains).

Radius of sharpest curves at switches : 119 metres (5·95 chains).

Shortest straight between reverse curves : 5·7 metres (6·2 yards).

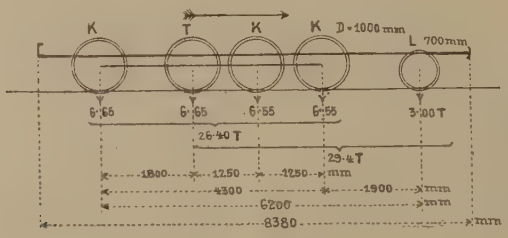
Steepest gradient considered : 27·6 per mil.

Year of purchase of locomotive : 1906.

b) Tank locomotive supplied by « Vagn & Maskin Fabriks A. B. Fahlun » (fig. 13).

Number : 4.

Arrangement of axles.



Adjustability of axles : the leading carrying axle has a lateral play of 50 millimetres (2 inches) on each side and the trailing coupled axle one of 15 millimetres ($^{19}/_{32}$ inch).

Heating surface :

Fire-box. . .	5·14 sq. metres	(55·32 sq. feet).
Smoke-tubes.	66·57	—	(716·58 —).
Total. . .	71·71 sq. metres	(771·90 sq. feet).

Grate area : 1·25 sq. metres (13·45 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 340 \times 500$ mill. ($1' 1\,^3/_8'' \times 1' 7\,^{11}/_{16}''$).

System of valve gear : Heusinger, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}940$ kilog. (15,300 lb.).

Highest admissible speed : 35 kilometres (21·7 miles) per hour.

System of brakes steam brake automatic : acting on three pairs of wheels.

Capacity for coal. 1·5 cubic metres (53 cubic feet); water, 5·2 cubic metres (1,145 English gallons).

—

Hvetlanda-Sässjö.

Radius of sharpest curves on the open line : 200 metres (10 chains).

Radius of sharpest curves at switches : 100 metres (5 chains).

Shortest straight between reverse curves : 15 metres (16·4 yards).

Steepest gradient considered : 20 per mil.

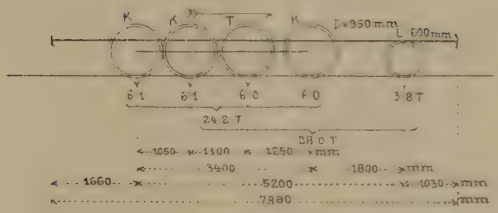
Year of purchase of locomotive : 1907.

c) Tank locomotive supplied by Motala, Werkstads Nya A. B. Motala.

Number : 1.

Adjustability of axles : the Bissel axle has a lateral play of 40 millimetres ($1\,^9/_{16}$ inches) and the trailing coupled axle one of 20 millimetres ($^{25}/_{32}$ inch).

Arrangement of axles.



Heating surface :

Fire-box . . .	5·57 sq. metres	(59·95 sq. feet).
Smokes-tubes.	47·17	—	(507·75 —).
Total. . .	52·74 sq. metres	(567·7 sq. feet).

Grate area : 0·9 sq. metre (9·68 sq. feet).

Working pressure : $p = 11$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 340 \times 460$ mill. ($1' 1\ 3/8'' \times 1' 6\ 1/8''$).

System of valve gear : Allan, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}160$ kilog. (13,580 lb.).

System of brakes steam brake automatic : acting on three pairs of wheels.

Capacity for coal, 0·9 cubic metre (31·8 cubic feet); water, 2·9 cubic metres (638·3 English gallons).

Kinnekulle-Lidköping-Åkantorp.

Radius of sharpest curves on the open line : 190 metres (9 1/2 chains).

Radius of sharpest curves at switches : 150 metres (7 1/2 chains).

Shortest straight between reverse curves : 35 metres (38·3 yards).

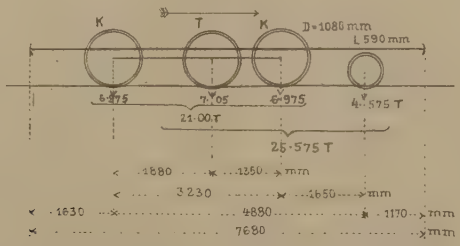
Steepest gradient considered : 16 per mil.

Year of purchase of locomotive : 1892, 1905 and 1908.

d) Tank locomotive supplied by Nydquist & Rohn, Trollhättan (fig. 15).

Number : 66.

Arrangement of axles.



Adjustability of axles : Bissel axle with a lateral play of 40 millimetres (1 9/16 inches).

Heating surface :

Fire-box . . .	5·1 sq. metres	(54·9 sq. feet).
Smokes-tubes.	45·7	—	(491·9 —).
Total. . .	50·8 sq. metres	(546·8 sq. feet).

Grate area : 0·8 square metre (8·61 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 320 \times 450$ mill. ($1' 0\ 5/8'' \times 1' 5\ 11/16$).

System of valve year : Allan, with flat valves.

Theoretical tractive effort according to the

formula $\frac{p \cdot d^2 \cdot l}{D}$ = 5,110 kilog. (11,265 lb.).

Highest admissible speed : 50 kilometres (31 miles) per hour.

Steambrake automatic acting on two pairs of wheels.

Capacity for coal, 0·75 cubic metre (26·5 cubic feet); water, 3 cubic metres (660 English gallons).

When using hit coal giving 7·500 heat units (13,500 B.T.U. per lb.), which evaporates 7 times its weight of water 175 horse-power are developed and a train weighing, 160 tons (157·5 English tons) gross, is hauled up a gradient of 16 per mil at a speed of 25 kilometres (15·5 miles) per hour.

Uddevalla Lelängen.

Radius of sharpest curves on the open line : 180 metres (9 chains).

Radius of sharpest curves at switches : 140 metres (7 chains).

Shortest straight between reverse curves : 10 metres (10·9 yards).

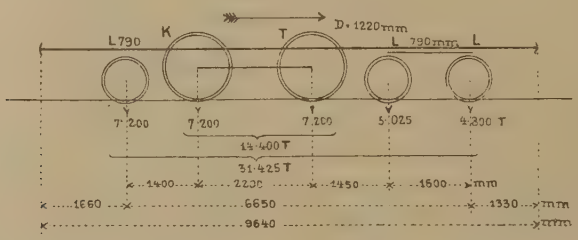
Steepest gradient considered : 16·67 per mil.

Year of purchase of locomotives : 1903.

e) Tank locomotive supplied by « Nydquist & Hohn », Trollhättan (figure 16).

Number : 8.

Arrangement of axles.



Adjustability of axles : one bogie and one Bissel truck.

Heating surface :

Fire-box . . .	6·25 sq. metres	(67·27 sq. ft.).
Smokes-tubes.	49·75 —	(535·52 —).
Total. . .	56·00 sq. metres	(602·79 sq. ft.).

Grate area : 0·90 square metre (9·68 sq. feet).

Working pressure : p = 11 atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l$ = 335 × 460 mill. (1′ 1 $^5/_{16}$″ × 1′ 6 $^1/_8$″).

System of valve gear : Allan, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \quad d^2 \cdot l}{D}$ = 4,720 kilog. (10,406 lb.).

Highest admissible speed : 65 kilometres (40·4 miles) per hour.

System of brakes steam brake automatic : acting on two pairs of wheels.

Steam heating : none.

Capacity for coal, 1 cubic metre (35·3 cubic feet); water, 4 cubic metres (880 English gallons).

When using pit coal which evaporates 7 times its weight of water 195 horse-power are developed and a train weighing 140 tons (137·8 English tons) gross, is hauled up a gradient of 16 per mil at a speed of 30 kilometres (18·6 miles) per hour.

—

Norra-Östergötland.

Radius of sharpest curves ou the open line : 300 metres (15 chains).

Radius of sharpest curves at switches : 150 metres (7 $^1/_2$ chains).

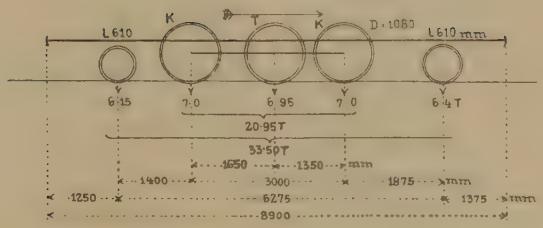
Steepest gradient considered : 16 per mil.

Year of purchasse of locomotive : 1908.

f) Tank locomotive supplied by « Nydquist & Hohn », Trollhättan.

Number : 4.

Arrangement of axles.



Adjustability of axles : two bissel trucks with a lateral play of 40 millimetres (1 $^{9}/_{16}$ inches).

Heating surface :

Fire-box . . .	6·04 sq. metres	(65·01 sq. feet).
Smoke-tubes .	53·99	—	(581·16 | —).
Superheater .	13·80	—	(148·54 | —).
Total. . .	73·83 sq. metres	(794·71 sq. feet).

Grate area : 0·9 sq. metre (9·68 sq. feet).

Working pressure : $p = 11$ atmospheres.

Temperature of steam : 300° C (572° Fahr.).

Twin-working.

Dimensions of cylinders :

$d \times l = 370 \times 460$ mill. ($1' 2\ ^{9}/_{16}'' \times 1' 6\ ^{1}/_{8}''$).

System of valve gear : Walschaerts, with Schmidt piston valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}400$ kilog. (14.110 lb.).

Highest admissible speed : 50 kilometres (31 miles) per hour.

System of brakes steam brake automatic : acting on three pairs of wheels.

Capacity for coal, 1·25 cubic metre (44·1 cubic feet) ; water, 4·0 cubic metres (880 English gallons).

When using pit coal which evaporates 7 times its weight of water 250 horse-power are developed and a train weighing 200 tons (196·8 English tons) gross, is hauled up a gradient of 16 per mil at a speed of 30 kilometres (18·6 miles per hour.

—

Västergötland Göteborg.

Radius of sharpest curves on the open line : 200 metres (10 chains).

Radius of sharpest curves at switches : 150 metres (7 $^{1}/_{2}$ chains).

Shortest straight between reserve curves : 40 metres (43·7 yards).

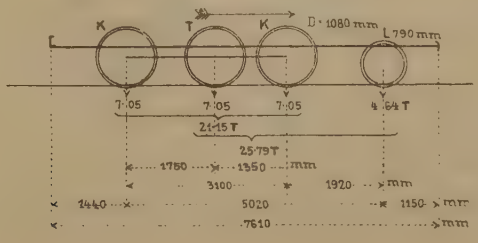
Steepest gradient considered 16·8 per mil.

Year of purchase of locomotive : 1901 to 1909.

g) Tank locomotive supplied by « Nydquist & Hohn », Trollhättan (fig. 17).

Number : 9.

Arrangement of axles.



Adjustability of axles : Bissel truck with a lateral play of 40 millimetres (1 $^{9}/_{16}$ inches).

Heating surface :

Fire-box. . .	5·65 sq. metres	(60·81 sq. feet).
Smoke-tubes.	49·70	—	(534·98 | — |).
Superheater.	11·20	—	(120·56 | — |).
Total . . .	66·55 sq. metres	(716·35 sq. feet).

Grate area : 1·1 sq. metres (11·84 sq. feet).

Working pressure : $p = 11$ atmospheres.

Temperature of steam 300° C. (572° Fahr).

Twin-working.

Dimensions of cylinders :

$d \times l = 370 \times 500$ mill. ($1' 2\,^{9}/_{16}'' \times 1' 7\,^{11}/_{16}''$).

System of valve gear : Walschaerts, with Schmidt piston valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}950$ kilog. (15·322 lb.).

Highest admissible speed : 50 kilometres (31 miles) per hour.

System of brakes Hardy vacuum automatic : acting on three pairs of wheels.

Steam heating : none.

Capacity for coal, 2·0 cubic metres (70·6 cubic feet); water, 8·0 cubic metres (1,760 English gallons).

When using pit coal which evaporates 7 times ist weight of water 280 horse-power are developed and a train weighing 200 tons (196·8 English tons) gross, is hauled up a gradient of 16 per mil at a speed of 30 kilometres (18·6 miles) per hour.

---

2. — *Stockholm-Rimbo Yärnvägs A. B.*

Stockholm-Roslagen Railways.

Radius of sharpest curve on the open line : 200 metres (10 chains).

Radius of sharpest curves at switches : 125 metres ($6\,^{1}/_{4}$ chains).

Shortest straight between reserve curves : 35 metres (38·3 yards) between curves having radii of 300 and 400 metres (15 and 20 chains).

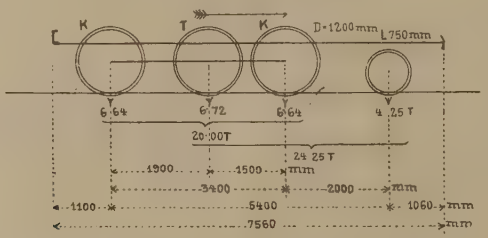
Steepest gradient considered : 20 per mil.

Year of purchase of locomotive : 1904 and 1906.

a) Tank locomotive supplied by « Vagn. & Maskin-Fabriks A. B. Fahlun ».

Number : 3.

Arrangement of axles.



Adjustability of axles : Bissel axle with a lateral play of 50 millimetres (2 inches).

Heating surface :

Fire-box . . .	6·5 sq. metres	(69 9 sq. feet).
Smoke-tubes .	54·0	—	(581·3 | — |).
Total. . .	60·5 sq. metres	(651·2	—	).

Grate area : 0·9 sq. metre (9·68 sq. feet).

Working pressure : $p = 12{\cdot}5$ atmospheres.

Compound-working.

Dimensions of cylinders :

$$d \times l = \frac{340}{510} \times 500 \text{ mill.} \left(\frac{1' 1\,^{3}/_{8}''}{1' 8''} \times 1' 7\,^{11}/_{16}'' \right)$$

System of valve gear : Heusinger von Waldegg, with flat valves.

Theoretical tractive effort according to the formula $0.75 \frac{p \cdot d^2 \cdot l}{D} = 4{,}560$ kilog. (10,053 lb.).

Highest admissible speed : 57 kilometres (35·4 miles) per hour.

System of brakes New York air brake automatic : acting on three pairs of wheels.

Capacity for coal, 2 cubic metre (70·6 cubic feet); water, 8 cubic metres (1,760 English gallons).

F. — Railways with a gauge of 914 millimetres (3 feet).

UNITED STATES OF AMERICA.

2. — *Chicago, Burlington and Quincy Railroad Company.*

This company operates about 120 kilometres (74 5 miles) of narrow-gauge road; it is used almost exclusively in serving various mines.

The service performed is mainly a switching service.

There are eight types of locomotives in use ; three of the 1 C type, one of the C type and four of the 1 D type.

Of these types, the chief particulars are given of one of the more powerful types of older design and of one of more recent design.

Radius of sharpest curves on the open line : 47 metres (2·35 chains).

Radius of sharpest curves at switches : 59 metres (2·95 chains).

Shortest straight between reverse curves : in some cases there in none.

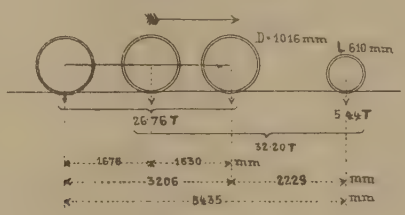
Steepest gradient considered : 82·5 per mil.

Year of purchase of locomotive : 1882.

a) Locomotive with separate tender supplied by Baldwin Works.

Number : 4.

Arrangement of axles.



Adjustability of axles : bissel truck, coupled axles with a lateral play of 4 millimetres ($^3/_{32}$ inch).

Heating surface :

Fire-box . . .	5·29 sq. metres	(56·9 sq. feet).
Smoke-tubes .	82·2 —	(884·8 —).
Total . . .	87·49 sq. metres	(941·7 sq. feet).

Grate area : 1·1 square metres (11·8 sq. feet).

Working pressure : $p = 10{\cdot}6$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 381 \times 508$ millim. (1′ 3″ × 1′ 8″).

System of valve gear : Stephenson, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 7{,}700$ kilog. (16,975 lb.).

System of brakes Westinghouse automatic : acting on three pairs of wheels.

Steam heating : none.

Capacity for coal, 5 cubic metres (176·6 cubic feet) ; water, 9·1 cubic metres (2,003 English gallons).

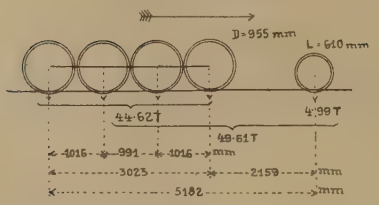
Newcastle-Wyoming bituminous pit coal used.

Year of purchase of locomotive : 1900.

Locomotive with separate tender supplied by Baldwin Works.

Number : 4.

Arrangement of axles.



Adjustability of axles: bissel truck, coupled axles with a lateral play of 4 millimetres ($^5/_{32}$ inch).

Heating surface:

Fire-box . .	7·61 sq. metres	(81·91 sq. feet.)
Smoke-tubes	126·8 —	(1,364·91 —).
Total . .	134·41 sq. metres	(1,446·82 sq. feet).

Grate area: 1·8 square metres (19·4 sq. feet).

Working pressure: $p = 12{\cdot}7$ atmospheres.

Twin working.

Dimensions of cylinders:

$d \times l = 432 \times 508$ millim. (1′ 5″ × 1′ 8″).

System of valve gear: Stephenson, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 12{,}500$ kilog. (27,557 lb.).

System of brakes Westinghouse automatic: acting on fourth pairs of wheels.

Steam heating: none.

Capacity for coal, 3 cubic metres (106 cubic feet); water, 9·1 cubic metres (2,003 English gallons).

Newcastle-Wyoming bituminous pit coal is used.

—

3. — *Pennsylvania Lines West of Pittsburgh.*

Waynesburg & Washington Railroad.

Radius of sharpest curves on the open line: 53·5 metres (2·675 chains).

Radius of sharpest curves at switches: 89·7 metres (4,485 chains).

Shortest straight between reverse curves: 18 6 metres (20·3 yards) between curves with radii of 57 and 87·6 metres (2·85 and 4·38 chains.)

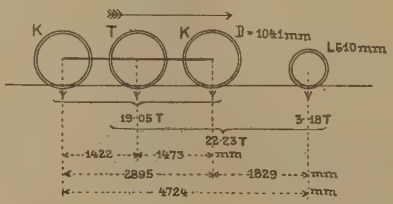
Steepest gradient considered: 25·6 per mil).

Year of purchase of locomotive: 1889 to 1903.

Locomotive with separate tender supplied by American Locomotive Co., Pittsburgh Works (figs. 18 and 19).

Number: 6.

Arrangement of axles.



Adjustability of axles: bissel axle, no mechanical restriction; coupled axles with a lateral play of 14 millimetres ($^9/_{16}$ inch).

Heating surface:

Fire-box . . .	5·57 sq. metres	(59·95 sq. feet).
Smoke-tubes.	40·9 —	(440·26 —).
Total. .	46·47 sq. metres	(500·21 sq. feet).

Grate area : 0·75 square metre (8·07 sq. feet).

Working pressure : $p = 10·6$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 305 \times 508$ millim. ($1' \times 1'\ 8''$).

System of valve gear : Link motion, with Allen balanced valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 4{,}810$ kilog. (10,582 lb.).

Highest admissible speed : 48·2 kilometres (29·9 miles).

System of brakes vacuum non-automatic : acting on two pairs of wheels.

Capacity for coal, 4 cubic metres (141 cubic feet; water, 7·3 cubic metres (1,607 English gallons).

When using pit coal a train weighing 112 tons (110·2 English tons) gross, is hauled up a gradient of 25·6 per mil at a speed of 9·65 kilometres (6 miles) per hour.

G. — Railway with a gauge of 950 millimetres (2 ft. 11 1/2 in.).

ITALY.

1. — *Italian State Railway.*

Radius of sharpest curves on the open line : 100 metres (5 chains).

Shortest straight between reverse curves : 60 metres (65·6 yards)

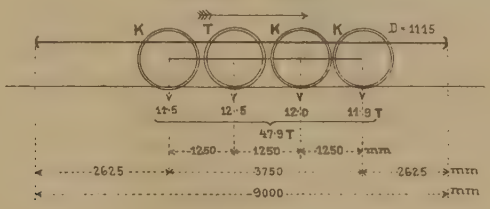
Steepest gradient considered : 25 per mil.

Year of purchase of locomotive : 1909.

Tank locomotive supplied by Schwarzkopf in Berlin.

Number : 12.

Arrangement of axles.



Heating surface :

Fire-box. . .	5·8 sq. metres	(62·43 sq. feet).
Smoke-tubes.	99·6 —	(1,072·12 sq. feet).
Total. . .	105·4 sq. metres	(1,134·55 sq. feet).

Grate area : 1·5 sq. metres (16·14 sq. feet).

Working pressure : $p = 14$ atmospheres.

Smoke consumer : Arch and screen in fire-box.

Twin working.

Dimensions of cylinders :

$d \times l = 410 \times 520$ millim. ($1'\ 4\ 1/8'' \times 1'\ 8\ 1/2$).

System of valve gear Walschaerts with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 11{,}070$ kilog. (25,790 lb.).

System of brakes vacuum automatic : acting on four pairs of wheels.

Capacity for coal 2 cubic metres (70·6 cubic feet); water, 5 cubic metres (1,100 English gallons).

Intended for Newport and Cardiff coal.

H. — Railways with a gauge 1,000 millimetres (3 ft. 3 3/8 in.).

GERMANY.

1. — *Alsace-Lorraine Railway.*

Radius of sharpest curves on the open line : 50 metres (2 1/2 chains).

Radius of sharpest curves at switches : 70 and 57 metres (3·50 and 2·85 chains).

Shortest straight between reverse curves : 2·26 metres (2·47 yards) between curves having a radius of 60 metres (65·6 yards).

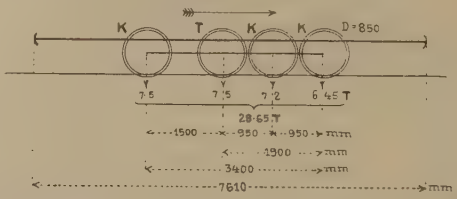
Steepest gradient considered 33 per mil.

Year of purchase of locomotive : 1903 to 1908.

b) Tank locomotive supplied by Hagans in Erfurt.

Number : 10.

Arrangement of axles.



Adjustability of axles : The trailing axle is in a Bissel truck and actuated by a loose shaft.

Heating surface :

Fire-box. . .	3·64 sq. metres	(39·18 sq. feet).
Smoke-tubes.	47·13 —	(507·32 —).
Total. . .	50·77 sq. metres	(546·50 sq. feet).

Grate area : 0·938 sq. metre (10·096 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 350 \times 400$ mill. ($1'1\,^{25}/_{32}'' \times 1'3\,^{3}/_{4}''$).

System of valve year : Heusinger with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} =$ 6,920 kilog. (15,256 lb.).

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes hand brake : acting on three pairs of wheels.

Capacity for coal 1 cubic metre (35·3 cubic feet); water, 3 cubic metres (660 English gallons).

When using pit coal giving 7,100 heat units (12,780 B. T. U. per lb.) which evaporates 5·5 to 6 times its weight of water, train weighing 70 to 80 tons (68·9 to 78·7 English tons) gross, is hauled up a gradient of 33 per mil at a speed of 15 to 12 kilometres (9·3 to 7·4 miles) per hour.

—

2. — *Bavarian State Railway.*

Neuötting-Altötting.

Radius of sharpest curves on the open line : 21 metres (1·05 chains).

Radius of sharpest curves at switches : 53 metres (2·65 chains) with grooved rails, otherwise 75 metres (3 ¾ chains).

Shortest straight between reverse curves 6 metres (6·6 yards) between curves having radii of 30 and 70 metres (1 ½ and 3 ½ chains).

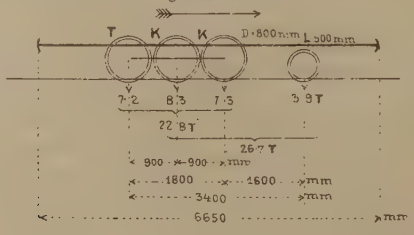
Steepest gradient considered 58·82 per mil.

Year of purchase of locomotive : 1906.

a) Tank locomotive supplied by Krauss & C°, Munich.

Number : 3.

Arrangement of axles.



Adjustability of axles : carrying axle in bissel truck with lateral play of 130 millimetres (5 1/8 inches) in each side; the third coupled axle has a play of 50 millimetres (2 inches).

Heating surface :

Fire-box. . .	4·25 sq. metres	(45·74 sq. feet).
Smoke-tubes.	32·38	—	(384·54 | —).
Superheater.	9·2	—	(99·03 | —).
Total. . .	45·83 sq. metres	(493·31 sq. feet).

Grate area : 0·79 sq. metre (8·50 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 380 \times 340$ millim. ($1' 3'' \times 1' 1\ 3/8''$).

System of valve gear : Heusinger with piston valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 7{,}364$ kilog. (16,235 lb.).

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes : Westinghouse automatic, acting on two pairs of wheels.

Capacity for coal 0·6 cubic metre (21·2 cubic feet); water, 2·5 cubic metres (550 English gallons).

When using briquettes from the Ruhr district giving 7,500 heat units (12,500 B. T. U. per lb.); 150 horse-power are developed and a train weighing 14 to 16 tons (13·8 to 15·7 English tons) gross, is hauled up a gradient of 48·1 per mil at a speed of 14 to 10 kilometres (8·7 to 6·2 miles) per hour.

—

3. — *Erfurt directorate.*

Radius of sharpest curves on the open line : 40 metres (2 chains).

Radius of sharpest curves at switches : 75 metres (3 3/4 chains).

Shortest straight between reverse curves : 11 metres (12 yards) between curves having radii of 70 and 150 metres (3 1/2 and 7 1/2 chains).

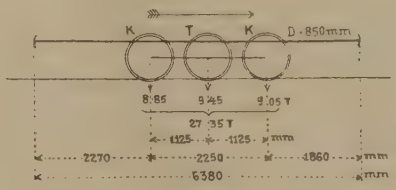
Steepest gradient considered : 33·3 per mil.

Year of purchase of locomotive : 1908.

Tank locomotive supplied by Ch. Hagans in Erfurt (fig. 20).

Number : 2.

Arrangement of axles.



Heating surface :

Fire-box. . .	3·81 sq. metres	(41·01 sq. feet).
Smoke-tubes.	47·21	—	(508·18 | —).
Total. . .	51·02	—	(549·19 | —).

Grate area : 0·857 sq. metre (9·225 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 350 \times 400$ millim. ($1' 1\ 25/32'' \times 1' 3\ 3/4''$).

System of valve gear : Heusinger with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}918$ kilog. (15,252 lb.).

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes Schleifer : acting on three pairs of wheels.

Capacity for coal, 1 cubic metre (35·3 cubic feet); water, 3·1 cubic metres (682 English gallons).

When using Ruhr coal, 189 horse-power

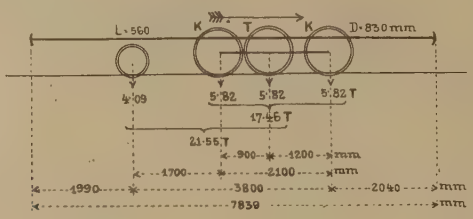
are developed and a train weighing 64 tons (62·9 English tons) gross, is hauled up a gradient of 25 per mil at a speed of 15 kilometres (9·3 miles) per hour.

Year of purchase of locomotive : 1899.

b) Tank locomotive supplied by Krauss & C°, Munich (fig. 21).

Number : 1.

Arrangement of axles.



Adjustability of axles : Carrying axle in Bissel truck with play of 20 millimetres ($^{13}/_{16}$ inch).

Heating surface :

Fire-box. . .	3·53 sq. metres	(37·99 sq. feet).
Smoke-tubes.	33·15 —	(356·83 —).
Total. . .	36·68 sq. metres	(394·82 sq feet).

Grate area : 0·65 sq. metre (6·99 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 300 \times 400$ mill. ($11\,^7/_8'' \times 1'\,3\,^3/_8''$).

System of valve gear : Heusinger with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 5{,}205$ kilog. (11,457 lb.).

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes Schleifer : acting on two pairs of wheels.

Capacity for coal, 0·76 cubic metre (26·8 cubic feet); water, 2·1 cubic metres (462 English gallons).

When using Ruhr coal, lumps and briquettes, 146 horse-power are developed and a train weighing 64 tons (62·9 English tons) gross, is hauled up a gradient of 25 per mil at a speed of 10 kilometres (6·2 miles) per hour.

—

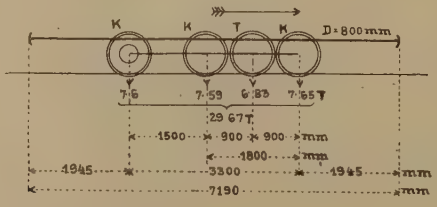
Year of purchase of locomotive : 1902.

c) Tank locomotive supplied by Ch. Hagans in Erfurt (fig. 22).

Number : 1.

Adjustability of axles : 4th axle is of the hollow-axle type.

Arrangement of axles.



Heating surface :

Fire-box. . . 3·64 sq. metres (39·18 sq. feet).
Smoke-tubes. 47·13 — (507·32 —).

Total. . . 50·77 sq. metres (546·60 sq. feet).

Grate area : 0·94 sq. metre (10·11 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 320 \times 400$ millim. ($1'\,^{19}/_{32}'' \times 1'\,3\,^{3}/_{4}''$).

System of valve gear : Heusinger, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6,144$ kilog. (13,545 lb.).

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes Schleifer : acting on three pairs of wheels.

Capacity for coal, 1 cubic metre (35·3 cubic feet); water, 3 cubic metres (660 Engl. gallons).

When using Ruhr coal, lumps and briquettes, 200 horse-power are developed and a train weighing 64 tons (62·9 English tons) gross, is hauled up a gradient of 25 per mil at a speed of 15 kilometres (9·3 miles) per hour.

—

4. — *Saxon State Railway.*

Radius of sharpest curves on the open line : 30 metres ($1\,^{1}/_{2}$ chains).

Radius of sharpest curves at switches : 25 metres ($1\,^{1}/_{4}$ chains).

Shortest straight between reverse curves : 10 metres (10·9 yards).

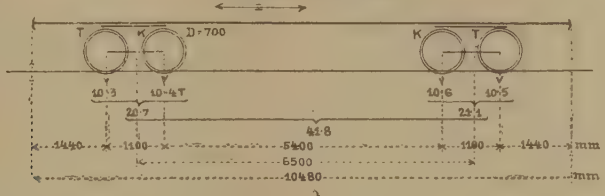
Steepest gradient considered : 25 per mil.

Year of purchase of locomotive : 1902.

Tank locomotive supplied by R. Hartmann, Chemnitz in Saxony (fig. 23).

Number : 3.

Arrangement of axles.



Adjustability of axles : Each pair of axles in a motor bogie of the Fairlie type.

Heating surface :

Fire-box. . . 7·77 sq. metres (83·63 sq. feet).
Smoke-tubes. 71·28 — (767·27 —).

Total. . . 79·05 sq. metres (850·91 sq. feet).

Grate area : 1·89 sq. metres (20·34 sq. feet).

Working-pressure : $p = 14$ atmospheres.

Compound-working.

Dimensions of cylinders :

$d \times l = \frac{2 \times 280}{2 \times 430} \times 380$ mill. $\left(\frac{2 \times 11'}{2 \times 1'5''} \times 1'3''\right)$.

System of valve gear : Heusinger, with flat valves, with Trick port.

Theoretical tractive effort according to the formula $1{\cdot}5\frac{p \cdot d_h^2 \cdot l}{D} = 8,232$ kilog. (18,148 lb.)

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes Brake : acting on two pairs of wheels.

Capacity for coal, 1·6 cubic metres (56·5 cubic feet); water, 3·2 cubic metres (704 English gallons).

—

5. — *Wurtemberg State Railway.*

Radius of sharpest curves on the open line : 80 metres (4 chains).

Radius of sharpest curves at switches : 70 metres ($3\,^{1}/_{2}$ chains).

*

Shortest straight between reverse curves : 5·4 metres (5·9 yards) between curves having radii of 475 and 378 metres (23 3/4 and 18·9 chains).

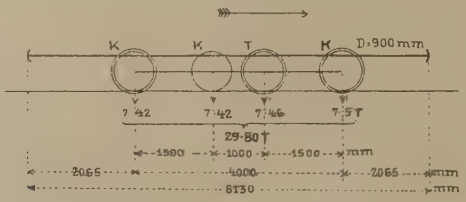
Steepest gradient considered : 40 per mil.

Year of purchase of locomotive : 1891 to 1899.

Tank locomotive supplied by the Maschinenfabrik, Esslingen (fig. 24).

Number : 3.

Arrangement of axles.



Adjustability of axles : first and fourth axle radially adjustable, on the Klose system, third axle has wheels without flanges.

Heating surface :

Fire-box. . .	5·42 sq. metres	(58·34 sq. feet).
Smoke-tubes.	65·20 —	(701·83 —).
Total. . .	70·62 sq. metres	(760·17 sq. feet).

Grate area : 1·02 sq. metres (10·97 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 340 \times 500$ millim. ($1' 1\,3/8'' \times 1' 7\,11/16''$).

System of valve gear : (Joy) Klose, with flat valves with Trick port.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 7{,}800$ kilog. (17,196 lb.).

Highest admissible speed : 30 kilometres (18·6 miles).

System of brakes : Westinghouse automatic : acting on one pair of wheels.

Steam heating.

Capacity for coal, 0·75 cubic metre (26·5 cubic feet) ; water, 2·4 cubic metres (528 Engl. gallons).

When using pit coal, Saar and Ruhr, mixed in equal parts which evaporates 7 to 7·5 times its weight of water, 190 horse-power are developed and a train weighing 50 tons (49·2 English tons) gross, is hauled up a gradient of 40 per mil at a speed of 15 kilometres (9·3 miles) per hour.

—

ARGENTINE REPUBLIC.

6. — *Argentine Northern Railway.*

Radius of sharpest curves on the open line : 450 metres (22 1/2 chains).

Radius of sharpest curves at switches : 180 metres (9 chains).

Shortest straight between reverse curves : 500 metres (547 yards).

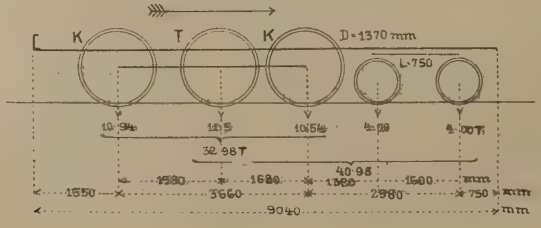
Steepest gradient considered : 12 per mil.

Year of purchase of locomotive : 1905.

a) Locomotive with separate tender supplied by Borsig.

Number : 9.

Arrangement of axles.



Adjustability of axles : carrying axles in a bogie.

Fire-box . . 11.26 sq. metres (121·20 sq. feet).
Smoke-tubes 108·70 ' — (1,170·08 —).

Total . . 119·96 sq. metres (1,291·28 sq. feet).

Grate area 1·5 square metres (16·14 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 430 \times 610$ millim. (1′ 5″ × 2″).

System of valve gear : Stephenson, with piston valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 9{,}880$ kilog. (21,782 lb.).

System of brakes vacuum automatic : acting on two pairs of wheels.

Capacity for wood, 10 cubic metres (353 cubic feet) ; water, 15 metres cubes (3,300 English gallons).

When using wood a train weighing 340 tons (335 English tons) gross, is hauled up a gradient of 10 per mil at a speed of 25 kilometres (15·5 miles) per hour.

—

FRANCE.

8. — *Orleans Railway.*

Coreze line.

Radius of sharpest curves on the open line : 100 metres (5 chains).

Radius of sharpest curves at switches : 107·35 metres (5·37 chains).

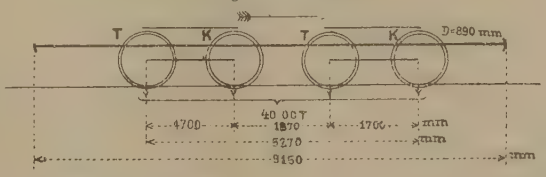
Shortest straight between reverse curves : 40 metres (43·7 yards).

Steepest gradient considered : 30 per mil.

Year of purchase of locomotive : 1905 to 1906.

c_2) Tank locomotive (fig. 25).

Arrangement of axles.



Adjustability of axles : each pair of axles is in a bogie of the Mallet type.

Heating surface :

Fire-box. . . 6·00 sq. metres (64·58 sq. feet).
Smoke-tubes. 72·00 — (775·02 —).

Total. . . 78·00 sq. metres (839·60 sq. feet).

Grate area : 1·57 sq. metres (16.89 sq. feet).

Working pressure : $p = 14$ atmospheres.

Working compound in fourth.

Dimensions of cylinders :

$$d \times l = \frac{2 \times 300}{2 \times 460} \times 460 \text{ mill.} \left(\frac{2 \times 11\ 7/8''}{2 \times 1'6''} \times 1'6'' \right).$$

System of valve gear : Walschaerts with flat valves.

Theoretical tractive effort according to the formula $1{\cdot}5\ p \cdot \frac{d_h^2 \cdot l}{D} = 9{,}768$ kilog. (21,535 lb.).

Highest admissible speed ; 40 kilometres (24·8 miles) per hour.

System of brakes vacuum automatic : Acting on fourth pairs of wheels.

Steam heating : none.

Capacity for coal, 1·2 cubic metres (42·4 cubic feet) ; water, 3·0 cubic metres (660 English gallons).

When using pit and pea-coal from Decazeville, train weighing 110 tons gross (108·2 English tons), is hauled up a gradient of 30 per mil at a speed of 18 kilometres (11·2 miles) per hour.

10. — *Aisne Department Railway.*

Tramway.

Radius of sharpest curves on the open line : 40 metres (2 chains).

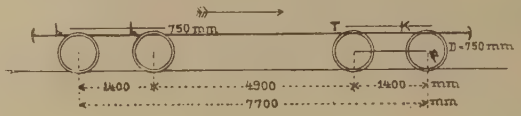
Radius of sharpest curves at switches : 40 metres (2 chains).

Steepest gradient considered : 44 per mil.

b) Year of purchase of automotor cars : 1907, supplied by Pinguely.

Number : 3.

Arrangement of axles.



Adjustability of axles : each pair of axles in one bogie.

Heating surface, total : 20·44 sq. metres (220·02 sq. feet).

Grate area : 0·44 sq. metre (4·73 sq. feet).

Working pressure : $p = 12{\cdot}1$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 230 \times 300$ millim. (9″ × 11 $^{7}/_{8}$″).

System of valve gear : Walschaerts, with flat valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 2{,}540$ kilog. (5,600 lb.).

System of brakes compressed air : acting on fourth pairs of wheels.

Capacity for coal, 0·43 cubic metre (15·18 cubic feet) ; water, 2·9 cubic metres (638 English gallons).

Coal from Mariemont is used.

—

PORTUGAL.

13. — *National Railway Company.*

Radius of sharpest curves on the open line : 150 metres (7 $^{1}/_{2}$ chains).

Radius of sharpest curves at switches : 100 metres (5 chains).

Shortest straight between reverse curves : 50 metres (54·7 yards).

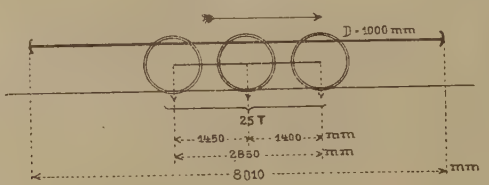
Steepest gradient considered : 18 per mil.

Year of purchase of locomotive : 1888.

b) Tank locomotive, supplied by the Maschinenfabrik Esslingen.

Number : 6.

Arrangement of axles.



Heating surface :

Fire-box. . .	6·00 sq. metres	(64·58 sq. feet).
Smoke-tubes.	64·00	—	(668·91 | — |).
Total. . .	70·00 sq. metres	(753·49	—	).

Grate area : 0·88 sq. metre (9·47 sq. feet).

Working pressure : $p = 10$ atmospheres.

Twin-working.

Dimensions of cylinders :

$d \times l = 350 \times 500$ mill. (1′ 1 $^{13}/_{16}$″ × 1′ 7 $^{11}/_{16}$″).

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 6{,}120$ kilog. (13,492 lb.).

Highest admissible speed : 45 kilometres (27·9 miles) per hour.

System of brakes Clayton vacuum automatic : acting on three pairs of wheels.

Capacity for coal, 0·8 cubic metre (28·2 cubic feet) : water, 3·0 cubic metres (660 English gallons).

Cardiff coal is used.

—

RUSSIA.

14. — *Riazan-Ural Railway.*

Urbach Ural, 346 kilometres (215 miles), Erschoff-Nicolajevsk, 94 kilometres (58·4 miles), Krasnyikut-Alexandrov 152 kilometres (94 miles), total, 592 kilometres (367·4 miles).

Radius of sharpest curves on the open line : 426 metres (21·3 chains).

Shortest straight between reverse curves : 0 metre.

Steepest gradient considered : 8 per mil.

Year of purchase of locomotive : 1894.

a) Locomotive with separate tender (fig. 27), supplied by Baldwin-Works.

Number : 4.

Adjustability of axles : carrying axle in a bissel truck.

Heating surface :

Fire-box. . .	4·59 sq. metres	(49·41 sq. feet).
Smoke-tubes.	37·22 —	(400·64 —).
Total. . .	41·81 sq. metres	(450·05 sq. feet).

Grate area : 0·87 sq. metre (9·36 sq. feet).

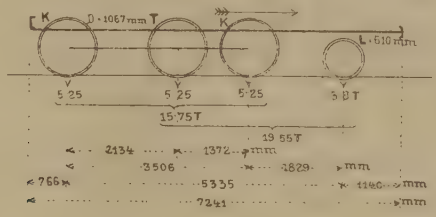
Working pressure : $p = 8$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 305 \times 406$ millimetres (1′ × 1′ 4″).

Arrangement of axles.



System of valve gear : Stephenson with Adams valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 2{,}840$ kilog. (6,261 lb.).

Highest admissible speed : 37·5 kilometres (23·3 miles) per hour.

System of brakes Hardy automatic : acting on the tender pairs of wheels.

Capacity for coal : naphta, 3·5 cubic metres (123·6 cubic feet); water, 7·5 cubic metres (1,650 gallons).

Naphta giving 10,800 heat units (19,440 B. T. U. per lb.) is used.

—

SWITZERLAND.

16. — *Rhetian Railway.*

Radius of sharpest curve on the open line : 100 metres (5 chains).

Radius of sharpest curves at switches : 90 metres (4 1/2 chains).

Shortest straight between reverse curves : 10 metres (10·9 yards) between parabolic transition curves.

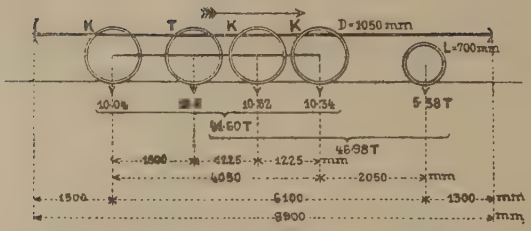
Steepest gradient considered : 45 per mil.

Year of purchase of locomotive : 1906 to 1909.

Locomotive with separate tender supplied by the Schweizerische Locomotivfabrik Winterthur.

Number : 11.

Arrangement of axles.



Adjustability of axles : carrying axle in bissel truck with play of 75 millimetres (3 inches); lateral play of coupled axles, 25 to 32 millimetres (1 inch to 1 $^{9}/_{32}$ inches).

Heating surface :

Fire-box . .	8·4 sq. metres	(90·42 sq. feet).
Smoke-tubes.	97·1	—	(1,045·21 | — |).
Superheater.	27·5	—	(296·01 | — |).
Total . .	133·0 sq. metres	(1,431·64 sq. feet).

Grate area : 2·1 sq. metres (22·60 sq. feet).

Working pressure : $p = 12$ atmospheres.

Smoke consumer Langer.

Twin working.

Dimensions of cylinders :

$d \times l = 460 \times 580$ millim. (1′ 6″ × 1′ 10 $^{7}/_{8}$″)

System of valve gear : Heusinger, with piston valves.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 14{,}000$ kilog. (30,865 lb.).

Highest admissible speed : 45 kilometres (27·9 miles) per hour.

System of brakes Hardy vacuum automatic : acting on two pairs of wheels.

Capacity for coal : 2·5 cubic metres (88·3 cubic feet) ; water 10 cubic metres (2·200 English gallons).

When using German and Belgian briquettes coal a train weighing 100 tons (98·4 English tons) gross, is hauled up a gradient of 35 per mil at a speed of 18 kilometres (11·2 miles) per hour.

I. — Railway with a gauge of 1,067 millimetres (3 ft. 6 in.).

BELGIUM.

1. — *Belgian National Suburban Railway Company.*

Locomotives of these types are constructed both for lines with a gauge of 1,000 millimetres and one of 1,067 millimetres (3 ft. 3 $^{3}/_{8}$ in. and 3 ft. 6 in.).

Radius of sharpest curves on the open line : 25 metres (1 $^{1}/_{4}$ chains).

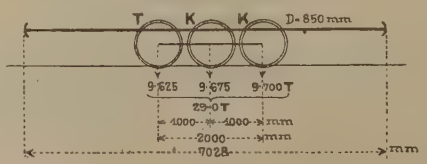
Steepest gradient considered : 70 per mil.

Year of purchasse of locomotives since 1884 of two similar types, of which the more powerful is given here.

Tank locomotive supplied by several Belgian locomotive works.

Number : 561.

Arrangement of axles.



Heating surface :

Fire-box. . .	6·10 sq. metres	(65·60 sq. feet).
Smoke-tubes.	42·02 —	(452·31 —).
Total. . .	48·12 sq. metres	(517·91 sq. feet).

Grate area : 0·945 sq. metre (10·172 sq. feet).

Working pressure : $p = 12$ atmospheres.

Twin working.

System of valve gear : Walschaerts, with flat valves and ports.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 2{,}205$ kilog. (4,861 lb.).

Highest admissible speed : 35 to 40 kilometres (21·7 to 24 8 miles) per hour.

System of brakes Handbrake : acting on two pairs of wheels.

Capacity for coal, 0·65 cubic metre (22·95 cubic feet); water, 1 cubic metre (220 English gallons).

When using Belgian pit coal which evaporates 8 times its weight of water, 118 horsepower are developed at a speed of 30 kilometres (18·6 miles) per hour.

NORWAY.

2. — *Norwegian State Railway.*

Radius of sharpest curves on the open line : 188 metres (9·4 chains).

Radius of sharpest curves at switches : 100 metres (5 chains).

Shortest straight between reverse curves : is not prescribed.

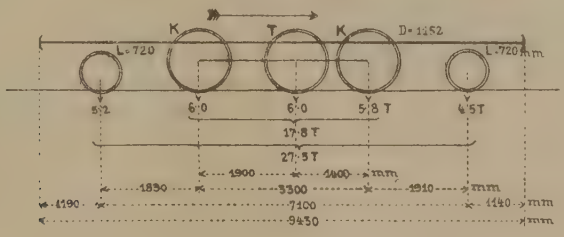
Steepest gradient considered : 23·8 per mil.

Year of purchase of locomotive : 1895 to 1908.

b) Tank locomotive.

Number : 6.

Arrangement of axles.



Adjustability of axles : leading axle in Bissel truck, play 70 millimetres (2 3/4 inches).

Heating surface :

Fire-box. . .	5·21 sq. metres	(56 08 sq. feet).
Smoke-tubes.	40 95 —	(440·79 —).
Total. . .	46·16 sq. metres	(496·87 sq. feet).

Grate area : 0·85 sq. metre (9·14 sq. feet).

Working pressure : $p = 10$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 330 \times 460$ millim. (1′ 1″ × 1′ 6″).

System of valve gear : Heusinger.

Theoretical tractive effort according to the formula $\frac{p \cdot d^2 \cdot l}{D} = 4{,}400$ kilog. (9,700 lb.).

Highest admissible speed : 55 kilometres (34·2 miles) per hour.

System of brakes compressed air automatic : acting on two pairs of wheels.

Steam heating : none.

Capacity for coal, 0·8 cubic metre (28·3 cubic feet) ; water, 2·2 cubic metres (484 English gallons).

RUSSIA.

3. — *Moscow-Windau-Rybinsk Railway.*

Radius of sharpest curves on the open line : 322 metres (16·1 chains).

Radius of sharpest curves at switches : 178 metres (8·9 chains).

Shortest straight between reverse curves : 313 metres (342 yards) between curves with radii of 639 and 958 metres (31·95 and 47·9 chains).

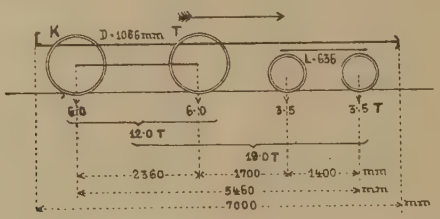
Steepest gradient considered : 6·6 per mil.

Year of purchase of locomotive : 1871 to 1878.

a) Locomotive with separate tender of three similar types, of which the most powerful is given here supplied by Evanseid, Doubs and Schwarzkopf.

Number : 9.

Arrangement of axles.



Adjustability of axles : Two carrying in a bogie.

Heating surface :

Fire-box . . .	5·30 sq. metres	(57·05 sq. feet).
Smoke-tubes .	40 —	(430 57 —).
Total. . .	45·30 sq. metres	(487·62 sq. feet).

Grate area : 1 sq. metre (10·76 sq. feet).

Working pressure : $p = 10$ atmospheres.

Twin working.

Dimensions of cylinders :

$d \times l = 254 \times 458$ mill. (10″ × 1′ 6″).

System of valve gear : Allan with flat valves.

Theoretical tractive effort according of the formula $\frac{p \cdot d^2 \cdot l}{D} = 2{,}770$ kilog. (6,107 lb.).

Highest admissible speed : 50 kilometres (31 miles) per hour.

Capacity for wood, 4·86 cubic metres (171·64 cubic feet) ; water 4·47 cubic metres (983 English gallons).

APPENDIX II.

2. — Summary of the answers relating to the first supplement subject XIX, littera A.

Is it advisable to protect the wheels and the moving parts by a metal cover ?

The administrations enumerated below use no such protective covers on the lines which fall within the scope of this report, and express no opinions as to their value :

8 (1). *Austrian State Railway.*

14. *Baltimore & Ohio Railroad.*

15. *Pennsylvania Lines West of Pittsburgh.* — The front end is protected by a so-called " pilot " or " cow-catcher ", which is essential in the case of trespassing men or animals being on the track. It is to be recommended.

17. *Paris-Lyons-Mediterranean Railway.*

19. *Eastern Bengal Railway.*

20. *North Western State Railway of India.* — This only runs on its own special track.

22. *Natal Government Railways.*

24. *Moscou-Vindau-Rybinsk Railway.*

25. *First Secondary Railway Company of Russia.*

26. *Swedish State Railway.* — 1·5 kilometres (0·93 mile) of street are also used by the railway.

27. *Stockholm-Rimbo Railway.*

28. *Swedish Federal Railway.* — On the Brunig line the street is not used.

(1) The numbers placed before the names of the administrations are the index numbers of the list given in appendix II.

a) *Length of streets, also used by the railway, in villages and towns. Length of highway, also used by the railway, outside villages and towns. Width of streets and highways.*

1. *Alsace-Lorraine State Railway.* — Two of the narrow-gauge lines have their own road-bed; the third, 22 kilometres (13·7 miles) long, is laid on streets; about 8·5 kilometres (5·28 miles) of it are inside villages and towns. The width of the streets varies between 8 and 10 metres (25 ft. 7 in. and 32 ft. 10 in.).

2. *Bavarian State Railway.* — The streets are also used, about 1·9 kilometres (1·2 miles) being inside continuous villages and towns, and 6 kilometres (3·7 miles) outside. The width of the streets varies between 4·9 and 20 metres (16 ft. 1 in. and 65 ft. 8 in.).

3. *Prussian-Hessian State Railway, Erfurt Directorate.* — The streets are also used, about 3·6 kilometres (2·2 miles) being inside continuous villages and towns, and 34 kilometres (21·1 miles) outside. The width of the streets varies between 9 and 15 metres (29 ft. 6 in. and 49 ft. 3 in.).

5 *Saxon State Railway.* — The streets are also used, 1·4 kilometres (0·87 mile) being inside continuous villages and towns, and 3 9 kilometres (2·4 miles) outside. The streets have a width of from 7·5 to 10 metres (24 ft. 7 in. to 32 ft. 10 in.).

6. *Wurtemberg State Railway.* — 0·675 kilometre (0·419 mile) of street inside continuous villages and towns, and 11·45 kilometres (7·11 miles) outside are used for the railway. These streets have a width of 5 metres (16 ft. 5 in).

9. *Bukovina Local Railway.* — All the nar-

row-gauge lines have special roads-beds of their own.

10. *Austrian Southern Railway.* — Streets inside continuous villages and towns are not used. Outside 1·35 kilometres (0 838 mile) of highway, 6 metres (19 ft. 8 in.) wide, are used by the Külmsdorf-Eisenkappel line, and 9·8 kilometres (6·1 miles) of highway, 9 metres (29 ft. 6 in.) wide, are used by the Mori-Arco-Riva line. All the other narrow-gauge lines have special road-beds of their own.

11. *Arad-Csanad Railway.* — 12 kilometres (7·5 miles) of street are used inside continuous villages and towns, and 75 kilometres (46·6 miles) outside; these have a width of from 10 to 20 metres (32 ft. 10 in. to 65 ft. 8 in.).

12. *Belgian National Suburban Railway Company.* — 1,704 kilometres (1,059 miles) are on unwidened streets and 318 kilometres (198 miles) are on widened streets.

16. *Orleans Railway.* — No streets are used inside continuous villages or towns. Outside them the Blois-St. Aignan line does not use the highway, nor does the Blanc Argent line; but 7·66 kilometres (4·76 miles) of the Coreze line are on highways having a width of 10 metres (32 ft. 10 in.), 6 metres (19 ft. 8 in.) of which are left clear for the ordinary wheeled traffic.

18. *St. Quentin-Guise and Aisne Department Railway.* — 2 kilometres (1·2 miles) of local line use the streets as well.

21. *Bombay, Baroda & Central India Railway.* — Streets and highways are not used.

---

b) *Are such coverings used?*

---

1. *Alsace-Lorraine Railway.* — Protective coverings are not used on our narrowgauge locomotives.

2. *Bavarian State Railway.* — Yes.

3. *Prussian Hessian State Railway* — No.

5. *Saxon State Railway.* — Yes, in the case of the Fairlie locomotive.

6. *Wurtemberg State Railway.* — Yes, in the case of the locomotives type T s 4, used on a gauge of 1 metre (3 ft. 3 3/8 in).

7. *Argentine Northern Railway.* — No.

9. *Bukovina Local Railway.* — None are used on the narrow-gauge locomotives. In the case of standard-gauge locomotives used for hauling on lines which also use streets, we have given up the use of such coverings.

10. *Austrian Southern Railway.* — On the Mori-Arco-Riva line such coverings were used when the line was opened to traffic in 1891; they were removed in 1896 and have not been used since. They were never in use on the other narrow-gauge lines.

11. *Arad-Csanad Railway.* — The whole mechanism is boxed in and runs in an oil-bath.

12. *Belgian National Suburban Railway Company.* — Yes.

13. *Fayoum Light Railways Company.* — Yes.

16. *Orleans Railway.* — On the St. Aignan-Blois line such coverings are used, but not on the other narrow-gauge lines.

18. *St. Quentin-Guise and Aisne Department Railway.* — In the local service no, in the tramway service yes.

21. *Bombay, Baroda & Central India Railway.* — The connecting and coupling roads and valve gear are cased in to protect them from dust. They are used on these engines but none are fitted to older types.

---

c) *What observations have been made as to the use of such coverings generally : As regards*

the shying of draft animals; As regards accidents, collisions with other vehicles? How does this effect the operation and the maintenance of the engine?

---

2. *Bavarian State Railway.* — In every respect favourable. The operation and the maintenance are simple.

5. *Saxon State Railway.* — No particular advantage has been observed. The shying of animals is not to be feared, if the mechanism is exposed, as the platform which extends beyond the mechanism hides it almost wholly from the animals. The platform also prevents damage in case any other vehicles approach too closely.

Protective coverings make it more difficult to attend to the mechanism.

6. *Wurtemberg State Railway.* — The protective covering has given goods results on lines which use the streets as well: in particular they protect the driving gear against the dust which is raised, and against the mud when it is bad weather, and prevent the accumulation of ice and snow in the mechanism in winter. As the reciprocating parts are hidden from view, animals are less apt to shy than if the protective coverings were absent.

The coverings reduce the effect of violent collisions; minor collisions become less dangerous as the protective covering prevents any contact with the moving parts.

The coverings give no particular trouble as regards the operation of the engine; as regards the maintenance of the latter, the coverings can easily and quickly be removed.

9. *Bukovina Local Railway.* — In the case of standard-gauge locomotives, used for traction on lines which also use streets, such coverings were at first used; but we gave them up because we found that animals shied as much at locomotives with coverings as at locomotives without.

10. *Austrian Southern Railway.* — On the Mori-Arco-Riva local line, when there was deed snow, a small amount of trouble arose as the coverings became undone because the doors projected slightly beyond the loading gauge. In order to prevent such an occurence, which might give rise to serious trouble, the coverings were removed.

On all the other narrow-gauge lines, the absence of coverings has never given rise to any accident or trouble.

Coverings make it more difficult to operate the engine, especially at roadside stations where the stops are short. The mechanism is not appreciably benefited by such coverings, unless they are dust-proof, as it is just the finely-powdered dust which penetrates the bearings of the mechanism and accelerates the wear.

12. *Belgian National Suburban Railway Company.* — When coverings are used, the mechanism wears much better, especially when the track is along dusty roads.

13. *Fayoum Light Railways Company.* — The coverings are efficacious with outside frame, as it is then possible to have them nearly dust-proof. The coverings must be at least 100 millimetres (4 inches) above rail-level. As a rule the points of collision are higher than the mechanism. The rubbing surfaces require less maintenance,

18. *St. Quentin-Guise and Aisne Department Railway.* — We are of opinion that their object is not so much for avoiding the scaring of animals, and accidents and collisions which are very rare, as for reducing the maintenance. But in order that this saving may be real, it is necessary that the protection should be complete, that is to say that the mechanism should be wholly enclosed. If it is not, partial protection is harmful rather than useful.

21. *Bombay, Baroda & Central India Railway.* — Oil is saved as no dust can reach the working parts. All parts are easily aceessible

and slide bars would give trouble from dust if not protected.

---

d) *Does the use of such coverings seem necessary, and under what condition? Is it to be recommended? Or does it appear superfluous?*

---

1. *Alsace-Lorraine Railway.* — We do not consider the use of coverings to be necessary.

2. *Bavarian State Railway.* — The use of such coverings seems necessary if the line runs for some distance alongside a street or highway or on it.

3. *Prussian-Hessian State Railway, Erfurt Directorate.* — No. The advantage would be counterbalanced by making the moving parts less accessible.

4. *Prussian-Hessian State Railway, Kattowitz Directorate.* — Coverings are not recommended, as they reduce the accessibility. There are no streets used where much dust could be produced.

5. *Saxon State Railway.* — It does not seem absolutely necessary to place protective coverings over the moving parts.

It is advisable to put a covering over the parts at the cylinders, in order to reduce the noise should a stuffing-box leak. Otherwise, coverings may be considered unnecessary under the existing conditions.

6. *Wurtemberg State Railway.* — Protective coverings are useful and to be recommended for lines on which there is danger of collision with vehicles and persons. The protective coverings should be properly designed so as to make it possible to take them down readily, so as to make it easy to operate the mechanism and make it accessible. It seems to us that such protective coverings are superfluous on lines wich have a road bed of their own.

7. *Argentine Northern Railway.* — The use of such metal coverings would be particularly advantageous in this case, owing to the great quantity of dust raised when running, as the track is not ballasted.

9. *Bukovina Local Railway.* — When the line passes over streets where there is much traffic, such coverings are to be recommended.

10. *Austrian Southern Railway.* — The use of such protective coverings does not seem to be necessary on our narrow-gauge lines.

12. *Belgian National Suburban Railway Company.* — Yes, particularly on lines running on streets or highways, or running alongside them.

13. *Fayoum Light Railways Company.* — We recommend the use of coverings, provided they are nearly air-tight, in the case of lines which run along dusty or sandy streets or highways.

The same statement is made as regards the Romagna steam tramway system.

16. *Orleans Railway.* — Coverings are recommended for those locomotives which have to run on dusty roads.

21. *Bombay, Baroda & Central India Railway.* — It entirely depends on the ballast. They are required on our road as there is so much sand and dust.

23. *Portuguese National Railway Company.* — We do not think it advisable to cover the wheels or the moving parts of the mechanism.

APPENDIX III.

3. — List of the administrations who sent answers to the list of questions relating to the second supplement of subject XIX, littera A.

GERMANY.

1. — Alsace-Lorraine Railway.
2. — Bavarian State Railway.
3. — Prussian-Hessian State Railway, Erfurt Directorate.
4. — Prussian-Hessian State Railway, Kattowitz Directorate.
5. — Saxon State Railway.
6. — Wurtemberg State Railway.

AUSTRIA AND HUNGARY.

a) Austria.

7. — Austrian State Railway.
8. — Bukovina Local Railway.

b) Hungary.

9. — Arad-Csanad Railway.
10. — Kaschau-Oderberg Railway.

BELGIUM.

11. — Belgian National Suburban Railway Company.

EGYPT.

12. — Société anonyme d'entreprise générale de travaux (Belgium). «Fayoum Light Railways Company. »

UNITED STATES OF AMERICA.

13. — Baltimore & Ohio Railroad.

FRANCE.

14. — Orleans Railway.
15. — Paris-Lyons-Mediterranean Railway.
16. — St. Quentin-Guise and Aisne Department Railway.

GREAT BRITAIN.

a) United Kingdom.

17. — Great Western Railway.

b) Empire of India and Colonies.

18. — Bombay, Baroda & Central India Railway.
19. — Central South Africa Government Railways.
20. — Natal Government Railways.

RUSSIA.

21. — Moscow-Vindau-Rybinsk Railway.
22. — First Secondary Railway Company of Russia.

SWEDEN.

23. — Swedish State Railway.

SWITZERLAND.

24. — Swiss Federal Railway.

Summary of the answers relating to the first supplement.

Is it advisable to have a footplate at each end of the locomotive? What regulations are there on the subject?

The following administrations have stated that no locomotives are used on the lines falling within the scope of this report, which have two footplates, and have expressed no opinion as to the utility or need of such an arrangement.

4 (1). *Prussian-Hessian State Railway, Kattowitz Directorate.*

5. *Saxon State Railway.* — This has platforms extending round the locomotives of the Fairlie type, but not with the object of driving the locomotive from the head of the train, as the cab is in the middle of the locomotive.

6. *Wurtemberg State Railway.*

7. *Austrian State Railway.*

10. *Kaschau-Oderberg Railway.*

13. *Baltimore & Ohio Railroad.*

15. *Paris-Lyons-Mediterranean Railway.*

18. *Bombay, Baroda & Central India Railway.*

19. *Central South Africa Government Railways.*

20. *Natal Government Railways.*

21. *Moscow-Vindau-Rybinsk Railway.*

22. *First Secondary Railway Company of Russia.* — There is no experience available.

23. *Swedish State Railway.*

The following administrations do not use locomotives with two footplates and do not consider them necessary.

1. *Alsace-Lorraine Railway.* — All of our narrow-gauge locomotives are tank locomotives with one footplate only. We consider a second footplate superfluous. The communication cord makes communication between the locomotive and the train possible.

3. *Prussian-Hessian State Railway, Erfurt Directorate.* — No need for this has ever become apparent in this district.

8. *Bukovina Local Railway.* — There is no second footplate and its absence gives rise to no inconvenience.

12. *Société anonyme d'entreprise générale de travaux. Fayoum Light Railways Company* and *Romagna steam tramway.* — The advantages are problematic; the staff is not in favour of it and fears accidents, and does not want to use them.

14. *Orleans Railway.* — Two footplates are useless in the case of our undertaking.

24. *Swiss Federal Railway.* — There are no second footplates and such are not used.

a) Diagram showing the arrangement of the handles used in driving the locomotives.

b) Can the locomotives be driven from either footplate?

c) Is it necessary to do stoking while running?

2. *Bavarian State Railway.* — *a)* The locomotives are tank locomotives; the footplate is

(1) The numbers placed before the names of the administrations are the index numbers of the list given in appendix III.

at one end and there is a small platform at the other. — *b*) No, only from the footplate. — *c*) Yes.

9. *Arad-Csanad Railway.* — The tractors have the footplate in the middle, affording a clear view in either direction.

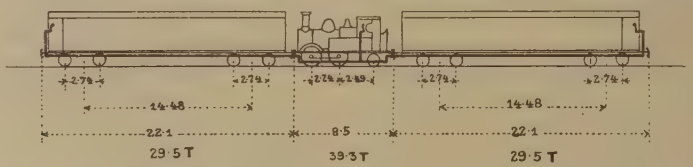
11. *Belgian National Suburban Railway Company.* — There is a footplate at each end of the locomotive, and the locomotive can be driven from either footplate. It is necessary to do stoking while running.

16. *St. Quentin and Aisne Department Railway.* — *b*) This railway has locomotives with a footplate at each end. The shaft by means of which the regulator is operated passes through the whole length of the boiler and has at each end a lever and handle, so that the regulator can be operated from either footplate. A lever is also placed on each footplate for working the reversing gear. These two levers are connected by a rod, which operates the valve gear, so that the cut-off may be set as desired from either footplate.

c) It is necessary to do stoking while running.

17. *Great Western Railway* (*Great Britain*). — Standard gauge.

a) The train consists of two cars, with a locomotive placed between them. The two cars have a driver's compartment at each end of the train, as shown in the adjoining sketch



b) The regulator of the locomotive can be operated from the footplate and from the driver's compartment in either car, by means of shafts which extend below the floor of the cars and under the locomotive, and are connected by flexible couplings.

c) It is necessary to do stoking while running.

---

d) What auxiliary means are provided to enable the employees on the two footplates to communicate with each other in those cases in which the locomotive can not be driven from either footplate?

What auxiliary means are available, in the case of locomotives running backwards, to enable the watchmen in charge of a given section of line to make a locomotive stop?

Is there any communication between the two footplates, and between these and the train, which can be used while the train is running?

---

2. *Bavarian State Railway.* — The footplate is connected with the front platform by a run-board with railing, which can also be used while the train is running. Hinged gangway footplates at the ends of the carriages give access to the train.

9. *Arad-Csanad Railway.* — There is no communication with the train.

11. *Belgian National Suburban Railway Company.* — The driver and the fireman see each other. There is no communication between locomotive and train.

16. *St. Quentin-Guise and Aisne Department Railway.* — The footplate of the locomotive and the platform of the carriage are next to each other.

17. *Great Western Railway* (*Great Britain*). — Communication between the train and the locomotive staff is effected by means of the prescribed steam-whistle signals and electric-bell signals.

e) *What advantages does this have: 1° As regards the safety of the working? 2° Does this arrangement make it possible to reduce the number of employees on the train, as compared with former arrangements? 3° Does this result in a reduction in the working expenses? 4° Does this result in a saving of capital expenditure, as compared with the use of turntables?*

f) *Is this arrangement recommended?*

---

2. *Bavarian State Railway.* — *e*) 1° The possibility of passing from the locomotive to the train and vice versa while running. — *e*) 2° Yes, because one man only is required for the locomotive. — *e*) 3° Yes. — *e*) 4° Turntables do not enter into consideration as tank locomotives are used. — *f*) Yes.

11. *Belgian National Suburban Railway Company.* — *e*) 1° The driver can see the track in front of him much better and this gives greater security. — *e*) 2° No. — *e*) 3° No. — *e*) 4° Yes. — *f*) Yes.

12. *Société anonyme d'entreprise générale de travaux.* — The use of two footplates is not recommended.

16. *St. Quentin-Guise and Aisne Department Railway.* — The staff can not be reduced. The capital outlay is less than for turntables. The use of two footplates is recommended.

17. *Great Western Railway* (*Great Britain*). — No reduction in the number of employees on the train results. The fireman is always on the footplate of the locomotive, while the driver is in the driver's compartment at the head of the train.

SECTIONAL DISCUSSION

Meeting held 6 July 1910 (morning).

MR. VON ZIFFER, VICE-PRESIDENT IN THE CHAIR

The President. (In French.) — We now begin the discussion of question XIX.

I call upon Mr. Jesser to give a summary of his report.

Mr. Jesser, *reporter.* (In German.) — The programme of the 5th section of the present session of the Congress includes, among other questions, that of the present system of construction of locomotives and rolling stock, and I have the honour to submit to you a report on this question, which is of extreme importance to the development of narrow-gauge railways.

In accordance with the usual practice, the administrations belonging to the Congress were requested, by the kind intermediacy of our general secretary, Mr. Weissenbruch, to place at my disposal the information about the types which have given good results, which was necessary in order to form an opinion of the present state of the question, and many railways have very kindly supplied me with detailed information about their practice.

I beg to refer you, in connection with this point as well as with all others which it would take us too long to examine here, to my report, together with its appendices, which you have received.

The many answers which I have received in answer to my list of questions lead us to conclude that the engineers specially dealing with this service show great interest in this subject, and as it is above all thanks to this participation that our deliberations can lead to a satisfactory result, I think that I express the feeling of the section by giving our collaborators our best thanks for the valuable assistance they have given to our common cause.

In a certain sense I may even venture to assert that the material supplied was too ample, for a preliminary examination showed that the proper study of modern rolling stock, its comparison with older types and the simultaneous consideration of the progress made, would be too voluminous a piece of work to be condensed into a single report. Accordingly I found myself compelled to limit myself to littera *A*, locomotives, or else I should have been unable to consider the subject from all desirable points of view, and I therefore propose to the section that the investigation of littera *B* of the question, relating

to the carriages and wagons, should be postponed to a future session of the Congress.

To pass now to the question we are going to consider today, I begin by mentioning in a general way that the information supplied by forty administrations relates to lines of nine gauges differing materially from each other, varying from 0·610 to 1·067 metres (2 feet to 3 ft. 6 in.), with nearly 1,400 locomotives of 107 different types.

Excluding for the moment one great undertaking which has more than 560 locomotives, and taking only the remaining railways, there are on the average only about eight locomotives per type, and this proportion is much more unfavourable in the case of many small undertakings.

It is beyond doubt that this promotes high prime cost and cost of working, which could be reduced by standardizing types and dimensions, and that this disadvantage is to a large extent due to the adoption of so many different gauges.

Let us now consider the locomotives of different gauges. The qualities which are of special interest to us in these locomotives, are the ability to run round curves as easily as possible, at a sufficient speed, at the expenditure of a tractive effort or power proportioned to the needs of the traffic, without exceeding the maximum axle-loads which a comparatively light track and roadbed can carry. From this point of view, exceptionally severe conditions are imposed above all on the types of locomotives used on narrow-gauge lines, for the necessity of reducing as much as possible the cost of construction of such lines leads in many cases to the adoption of sharp curves and of steep gradients.

Now, although in making a comparative study of the different types, the tractive efforts which can be developed under different conditions of profile can easily be deduced from the adhesive weight and the total weight, yet matters are altogether different as regards the power which assuming all the chief dimensions to be properly proportioned to each other, is subordinated to a certain number of factors. Such are the heating surface, its division between fire-box and smoke tubes, the working pressure, the temperature of the steam, the simple or double expansion of the steam, finally, all the factors affecting the heating, such as the nature and the properties of the fuel, the strength of the draft and the skill of the locomotive crews. Even excluding the latter factors, which have preponderating influence on the power obtainable and can hardly be determined numerically, the first set of factors is already not easy to elucidate sufficiently to obtain an exact idea of the subject. It hence appeared necessary to make, by way of comparison, a uniform determination of the powers.

As the ordinary data relating to the evaporative power and the consumption of steam apply usually to locomotives with large fire-boxes, they cannot be utilized as they stand for the conditions which we are considering, and the determination of the power is based on experimental coefficients determined during a series of trial runs made with locomotives on narrow-gauge lines. According to the results obtained, the working pressure in atmospheres multiplied by the fire-box heating surface plus quarter the smoke-tube heat-

ing surface, repesents, with sufficient approximation, the available output in horse-power, when Cardiff coal is used and the draft is brisk. In cases of superheating and compounding, this figure for the power can in each case be increased by over 10 per cent.

If we analyse the information supplied about the different types of locomotives, taking as basis the considerations just brought forward, we find that the following measures have been used with success to increase the power of the new as compared with the older types :

1° Increasing the working pressure of the boilers;

2° Superheating the steam;

3° Compounding.

The *working pressure* varies, in the case of ordinary locomotive boilers, between 8 and 14 atmospheres; in the great majority it amounts to 12 atmospheres and is most frequently fixed at this figure which may now be considered as standard. Pressures of between 12 and 13 atmospheres have been in use on fifteen types since 1896, and pressures of between 13 and 14 atmospheres have been in use on four types, since 1901, on German, French and Italian railways. This excellent method of increasing the power, which involves a comparatively slight increase in the weight of the locomotives, could be used all the more readily in the case of narrow-gauge railways, as the increase in the temperature of the walls of the boiler, an increase corresponding with the pressure, exercises, owing to the relative shortness of the fire-boxes, a less injurious influence on the stays than in the case of large fire-boxes, and further progress in this direction is to be expected.

Superheating the steam has been introduced since 1901 on six types, and now goes up to 300° C. (572° Fahr.). It is adopted above all in countries where fuel is scarce, and it may be concluded that the better utilization of the latter has contributed towards the selection of this system.

Compounding has been used on a large scale since 1892; according to the information received, it is applied on fourteen types of engines. Five of these, having two independent motor trucks, are equipped with four cylinders, while the others, where space is more limited, only have two. Compounding everywhere followed the introduction of medium pressures and above all that of high pressures, exceeding 12 atmospheres.

Among the locomotives designed for similar axle-load limits and lines of similar kind, the most powerful are those which have one or more of the improvements just described. The following may be mentioned :

Lines with a gauge of 610 millimetres (2 feet) : 4-6-2 tank locomotive of the Natal Government Railways, giving 215 horse-power, or 8·13 per ton of weight of the locomotive, the working pressure being 11·6 atmospheres.

Lines with a gauge of 750 millimetres (2 ft. 5 1/2 in.) : 0-8-0 tank locomotive of the Saxon State Railway, giving 250 horse-power, or 8·7 per ton of weight of the locomotive, with two cylinders, compound working and a pressure of 14 atmospheres.

Lines with a gauge of 760 millimetres (2 ft. 5 15/16 in.) : 0-6-4 tank locomotive of the Austrian State Railway, giving 280 horse-power, the highest power rela-

tively to the weight of the locomotive, namely 10·57 horse-power per ton of gross weight. This is a compound, with a working pressure of 13 atmospheres.

Lines with a gauge of 890 millimetres (2 ft. 11 3/64 in.) : 2-6-2 tank locomotive of the Swedish State Railway, giving 280 horse-power, or 8·37 per ton of weight of the locomotive. The boiler works at a pressure of 11 atmospheres and has a superheater.

Lines with a gauge of 950 millimetres (3 ft. 1 3/8 in.) : 0-8-0 tank locomotive of the Italian State Railway, giving 430 horse-power, or 8·98 per ton of weight of the locomotive. The working pressure is 14 atmospheres.

Lines with a gauge of 1 metre (3 ft. 3 3/8 in.) : 0-4 + 4-0 tank locomotive of the Saxon State Railway, giving 395 horse-power, or 9·43 per ton of weight of the locomotive; compound, 14 atmospheres. Also 0-4 + 4-0 tank locomotive of the Orleans Railway, giving 370 horse-power, or 9·25 per ton of weight of the locomotive; compound, 14 atmospheres.

Appreciably higher powers have been obtained by locomotives with separate tender and by the use of heavier axle-loads, in the case of lines where conditions are favourable. In this connection I may mention, for purposes of comparison, the following :

Lines with a gauge of 762 millimetres (2 ft. 6 in.) : 2-8-2 locomotive, with separate tender, of the Bengal-Nagpur Railway (Empire of India), giving 410 horse-power, or 6·95 per ton of gross weight; working pressure, 12 atmospheres.

Lines with a gauge of 914 millimetres (3 feet) : 2-8-0 locomotive, with separate tender, of the Chicago, Burlington, and Quincy Railway, giving 500 horse-power, working pressure 12 7 atmospheres. This great power is due to the heavy axle-load, 12 tons. An interesting feature of this type is that although it has a rigid wheel-base of 3·023 metres (9 ft. 11 in.), for the four coupled axles, yet it can run round curves having a radius of 47 metres (2·35 chains), without any special device except giving the axles a slight lateral play in their bearings. An increase in the wear of the tires and rails has been preferred to the use of complicated gear for giving the coupled wheels radial adjustment.

Lines with a gauge of 1 metre (3 ft. 3 3/8 in.) : 4-6-0 locomotive, with separate tender, of the Argentine Northern Railway, giving 460 horse-power, or 6·23 per ton of gross weight, with a working pressure of 12 atmospheres. Finally, there is the 2-8-0 locomotive with separate tender, of the Rhetian Railway, the most powerful of all the types, giving 520 horse-power, with a working pressure of 12 atmospheres, and using superheated steam.

We now pass to the second principal property, the tractive effort. We may mention, as of particular interest, the types making it possible to increase the *adhesive weight* beyond the limits feasible when rigid wheelbases are used.

Apart from allowing suitable play in the axle-boxes and having no flanges on some of the coupled wheels, the devices adopted for this purpose can be classified into two chief groups :

1° Having individual pairs of wheels with radial adjustment;

2° Having sets of driving wheels the axles of which are mounted in separate frames.

In those two cases, the driving is effected either purely by mechanical transmission of the action of a pair of chief steam engines, or by a special and complete pair of steam motors for each bogie. Altogether thirteen of these designs exist, in which the object aimed at is attained more or less completely, sometimes, it is true, at the price of great complication; thus there are eight types with radial pairs of wheels and five types with bogies with independent motors.

The first group includes a tractor with two free flexible axles each of which is driven, by a two cylinder de Dion-Bouton engine, with toothed-gear transmission; also seven types of 0-8-0 tank locomotives, two of which have a single free flexible axle and five have two flexible axles. One of the latter is on the Klose system, with mechanical device to provide for the change of length of the coupling rod; all the others are on the Klien-Lindner system, in which the power of the engine is transmitted to a rigid coupled shaft and its torque to pairs of radial wheels mounted by means of a hollow axle concentric with the shaft.

These devices make it possible to obtain, when the axle-loads are 6 to 7·6 tons, an adhesive weight of from 24 to nearly 30 tons, and although the total wheelbases are 3·900 to 4·050 metres (12 ft. 9 $^{9}/_{16}$ in. to 13 ft. 3 $^{1}/_{2}$ in.), to run round curves having a radius of as little as 40 metres (2 chains) on the open line and of 35 metres (1 $^{3}/_{4}$ chains) at switches.

Among the designs with *two motor bogies*, I must mention a type on the Hagans system, used on the Prussian-Hessian State Railway, on lines having a gauge of 785 millimetres (2 ft. 6 $^{29}/_{32}$ in.). The power developed by a single-expansion engine which is fixed to the main frame drives three pairs of rigid wheels and also two axles of a bogie, to which it is transmitted by means of articulated levers.

With the very moderate axle-load of 5·5 tons, it was possible to obtain an adhesive weight of over 27 tons, and although the total driving-wheel base is 4·650 metres (15 ft. 3 in.), it is possible to run round curves having a radius of 35 or 40 metres (1 $^{3}/_{4}$ or 2 chains).

But by far the easiest method of adapting long wheelbases to unfavourable curves is the use of two driving bogies, each actuated by a complete and independent pair of steam engines.

This design is represented by two different types. The older has two driving bogies, movable relatively to the main frame plates, while the more recent has one driving bogie in the main frame and another which is movable. The Saxon State Railway has some of the former type, on the Meyer system, in use on lines with a gauge of 750 millimetres (2 ft. 5 $^{1}/_{2}$ in.), and some of the latter type, on the Fairlie system, with its characteristic double boiler, on 1 metre (3 ft. 3 $^{3}/_{8}$ in.) gauge lines.

Quite recently the firm of Beyer, Peacock & Co., Limited, of Manchester, has again tried this system as improved by Mr. Garratt, and by placing the two driving bogies at the ends of the main frame plates in front and behind the boiler of the locomotives, it has obtained sundry advantages from the point of view of free development of the different details. Locomotives of this kind have recently been built for the Tasmanian Government Railway.

The Mallet-Rimrott system, with a movable driving bogie, has been applied

to a type built for the Wurtemberg State Railway and to one intended for the Orleans Railway.

To sum up, assuming the maximum axle-loads to be equal, it is not possible to obtain, with these locomotives of the 0-4 + 4-0 type, a greater adhesive weight than with the 0-8-0 type with flexible coupled axles. On the other hand, it is possible to have a much longer wheelbase, so that the weight is distributed more advantageously. Consequently, this design makes it possible to increase the adhesive weight, with a suitably-strengthened track, without extra fatigue of the substructure.

At present, axle-loads of 5·49 to 10·6 tons are used, giving an adhesive weight of 27·15 to 41·8 tons. The wheelbases vary between 4·400 and 7·600 metres (between 14 ft. 5 in. and 25 feet), and the ease of negociating curves is such that with the longest wheelbases it is possible to run round curves having a radius of 30 or 25 metres (1 $^1/_2$ or 1 $^1/_4$ chains).

We have now examined in detail the chief different types of locomotives.

We may assert with satisfaction not only that locomotive builders have always been able to meet the most severe demands made when new lines were schemed, but also that during the few tens of years that such lines have been operated, quality coefficients have been obtained which in many cases are twice, or even more, as good as at first.

Now, however satisfactory these considerations may be, we must not dwell any further on them, for the question of the latest locomotive types could not have as its sole object the collection of data, although these are of considerable value for determining the capacity of such lines; but what formed its real object were the conclusions, to be drawn from the large total of the brain work which has been devoted in each individual case to the design of the different types, in the manufacturing countries of the whole world.

If in the first place we examine the influence exercised by the plan and profile of the line and the strength of the track on the development of the locomotives, in order to ascertain how to obtain the most favourable combination of track and of operation, we come to the logical conclusion that in the case of new lines the track should be designed to suit those properties of the locomotives, which can be at present obtained with good designs, and which are required not only for the traffic immediately to be expected, but also for a traffic which has increased to a corresponding extent.

Starting from this point of view, we shall in what follows enumerate, and give reasons for, those proposals which we should as a rule recommend, when it is a question of building new narrow-gauge lines for public traffic, to be operated by means of steam locomotives.

In the second place, we have to consider the measures which are advisable when acquiring new locomotives for existing lines, so as to obtain the power necessary for coping with the growing traffic, if the existing older types no longer suffice for this purpose.

Although these two points are not expressly laid down in the original wording of the question which is to be discussed, yet they necessarily follow from the examination of the subject, and indeed, what other body or corporation could be more able and more justified to

recommend the adoption of certain principles, recognized as advantageous, than the Congress of the administrations which operate the existing lines and not only have acquired wide experience on the subject, but also have suffered from the consequences of difficulties in operation, which have in many cases resulted from small economies at the time of construction which were quite out of proportion to the increase in the working expenses which resulted.

In the case of the separate points which are to be considered, we give in each case the position taken by the German *Verein* as laid down in *Grundzüge für den Bau und die Betriebseinrichtungen der Lokalbahnen.*

These principles are not, as they stand, suitable for at discussion the Railway Congress, because the ground covered is much wider, and because it is by no means the case that all principles which may give excellent results in individual cases, can also be applied generally, particularly if the necessary preliminary conditions are not the same; they are, however, of such importance from the point of view of narrow-gauge railways, that, on the one hand, they could not be omitted without leaving lacunæ, and, on the other, they give many important points useful in the solution of the question generally.

The subject itself may be subdivided as follows :

A) *Track :*

1° Gauge; 2° gradients; 3° curves; 4° wheel-loads.

B) *Locomotives :*

1° Increase of power; 2° increase of adhesive weight.

A. — *Conclusions as regards track.*

1° The evolution of such a large number of different *gauges,* as described above, which in many cases only show very small differences, cannot be looked upon as an absolute necessity for the proper designing of the lines; and taking into consideration the resulting increase in the number of locomotive types and their consequent greater cost of construction and of maintenance, the selection of any other gauge than those already in existence must be looked upon as disadvantageous to the development of the narrow-gauge railway industry.

Taking into consideration that it has been possible to construct metre (3 ft. 3 3/8 in.) gauge locomotives which can run round as sharp curves as locomotives of smaller gauge, curves with a radius of as little as 30 metres (1 1/2 chains) and in one case even of 21 metres (1·05 chains), and also taking into consideration that it is possible to design, for this gauge, locomotives of considerable power, more capable of operating a growing traffic than would be the case with a narrower gauge, I think that the metre (3 ft. 3 3/8 in.) gauge is particularly advantageous in the cases where the new lines to be built are not directly connected with narrow-gauge lines of different gauge.

The German *Verein* has laid down the following conclusions in *Grundzügen*, paragraph 2, section 2 :

The gauge of 1,000 millimetres or of 750 millimetres (3 ft. 3 3/8 in. or 2 ft. 5 1/2 in.), is recommended for narrow-gauge local lines. In the case of minor railways, a gauge of 600 millimetres (1 ft. 11 5/8 in.) is still admissible. If a narrow-gauge system of larger

extent, having another gauge, already exists, it is advisable also to select this gauge for any new lines added to it.

Such a definite wording of this principle could hardly be adopted by the Congress, if only on account of the different systems of weights and measures, the general recommendation of a gauge of 1 metre (3 ft. 3 3/8 in.), without excluding other gauges which already exist, would better suit the objects which we are here considering; and it might be added that for lines which are to carry public traffic, the gauge of 600 millimetres (1 ft. 11 5/8 in.) is the narrowest that can be recommended.

2° The gradients used on the different lines show much variety and it may here be mentioned that longish gradients of 25 to 30 per mil are reported by nine administrations, of up to 35 per mil by six, of up to 40 per mil by three and of up to 45 per mil by three administrations, while gradients of 58·8, 70 and 82·5 per mil were each reported by one administration, and we may assume that the latter is the limit of what is ordinarily practicable in this way.

The development of the locomotive is not so much hampered by the presence of steep gradients, as it is by the other difficulties presented by the track. On the other hand, for a given horse-power, the gross ton-mileage is materially reduced by the reduction of the train weight including the load on the carrying wheels of the locomotive and of the tender, if any, proportionately to the adhesive weight of the locomotive.

This circumstance makes it evident that it is uneconomic to have excessive gradients on lines where the trains are hauled by steam locomotives, and this the more so, the smaller the ratio of the length of the steep gradients to the total length of the line.

Grundzüge prescribes in this respect in paragraph 21, section 1 :

> The gradient on adhesion railways shall as a rule not exceed 40 per mil (1 : 25).

The main statement quoted can be recommended in its general form, as it expresses that it is desirable not to have gradients steeper than 40 per mil; the qualification " as a rule " allows the engineer planning the line to select steeper gradients in special cases after careful consideration of all the circumstances, for and against, particularly of the higher initial outlay or cost of working.

3° The curves also show very great differences; we find everything from a very large minimum radius down to a radius of 21 metres (1·05 chains).

The dimensions have a very great effect both on the service and on the design of the locomotives.

In the first place, they affect the admissible speed, and we will here only note that the maximum reported speeds of over 50 and up to 65 kilometres (over 31 and up to 40·4 miles) per hour are as a rule limited to lines having curves with a minimum radius of 180 metres (9 chains), while one administration reports a minimum radius of 70 metres (3 1/2 chains) and a maximum admissible speed of 64·4 kilometres (40·0 miles) per hour.

On sharp curves, the maximum speeds for which the locomotives are designed are consequently reduced; they amount,

on the average, to about 40 kilometres (24·8 miles) per hour with radii of 60 metres (3 chains) and to 30 kilometres (18·6 miles) per hour with radii of 40 metres (2 chains).

Grundzüge prescribes in this respect in paragraph 22, section 1, clause *c* :

The radius of curves on narrow-gauge lines shall as a rule not be less than :

50 metres (2 1/2 chains) on lines with a gauge of 1,000 millimetres (3 ft. 3 3/8 in.);

40 metres (2 chains) on lines with a gauge of 750 millimetres (2 ft. 5 1/2 in.);

25 metres (1 1/4 chains) on lines with a gauge of 600 millimetres (1 ft. 11 5/8 in.).

Smaller radii can be used on all these lines, if the rolling stock is specially designed for running round sharp curves.

Then prescriptions follow as to the transition curves and the length of straights between reverse curves, which are to be at least 10 metres (32 ft. 10 in.) in length between the two superelevation gradients.

If the three dimensions here considered : gauge, rigid wheelbase and radius of curve, are directly proportionate to each other, the axles of the vehicles in all cases form the same angles with the radii of the curve.

But as the length of the locomotives and consequently of the most advantageous wheelbase does not decrease proportionately to the gauge, the need arises not to establish a direct proportion between the gauge and the radii of the curves, but to have a greater ratio between these two dimensions in the case of narrower gauges than in that of wider gauges.

Taking this circumstance into consideration, and also the existing lines, it seems advisable to place the matter on a simpler basis and to recommend the general adoption of the radius of 40 metres (2 chains) as a minimum, and to make any further reduction in this dimension dependent on the use of rolling stock which is so equipped that the axles have the required adjustability on the curves.

The straights between reverse curves should be at least as long as the greatest distance between bogie centres of any vehicle, if no guard rails are laid at these curves.

4° The admissible axle-loads and the admissible loads per metre of track are, among all the conditions mentioned, the most important factors in the designing of powerful locomotives, particularly in the case of lines with steep gradients

When we considered the different types of locomotives, we drew particular attention to the fact that some of the most powerful locomotives, giving the greatest tractive efforts, were designed for lines with very unfavourable curves, as it was possible to have great axle-loads.

Grundzüge prescribes, under construction and maintenance of rolling stock, in paragraph 41, section 2 :

The following maximum wheel-loads, measured in a state of rest, are recommended for the following gauges :

GAUGE.	WHEEL-LOAD.
1 metre (3 ft. 3 3/8 in.).	4·5 tons (4·4 English tons).
750 millimetres (2 ft. 5 1/2 in.).	4 tons (3·9 English tons).
600 millimetres (1 ft. 11 5/8 in.).	3·5 tons (3·4 English tons).

It is true that in practice these maximum wheel-loads recommended are not always attained; on the other hand, they are often materially exceeded.

It does not seem advisable to include such "maximum wheel-loads recommended" in our conclusions, as they would tend to limit the development of the power of the locomotives even more than many of the other difficulties of narrow-gauge lines, such as the curves and gradients, and therefore we propose the following wording : "An axle-load of 10 tons (9·8 English tons) is recommended for lines having a gauge of 1 metre (3 ft. 3 3/8 in. ; it is advisable, particularly on lines with steep gradients and on lines with sharp curves, to have as heavy axle-loads as possible."

B. — *Conclusions as regards locomotives.*

1° Taking into consideration the detailed investigation I have made of this subject, I recommend, in order to obtain locomotives of the *power* suited to the requirements of the traffic :

a) Increasing the working pressure to 14 atmospheres;

b) Superheating the steam to 300° C. (572° Fahr.);

c) Compounding.

One or more of these measures can be applied simultaneously, according to the circumstances of each case.

2° *The increase of the adhesive weight* beyond the figure which is determined by the maximum wheelbases for given minimum radii, by the admissible axle-loads and the maximum admissible loads per metre of track, is in the case of lines with steep gradients just as important a question as the increase of power.

Grundzüge recommends in paragraph 50 and 78 :

Locomotives and rolling stock which are to be used on lines where the under-mentioned curves frequently occur on the open line, should have rigid wheelbases not exceeding :

CURVES HAVING A RADIUS.	RIGID WHEELBASE	
	OF LOCOMOTIVE.	OF CARRIAGES.
25 metres (1 1/4 chains).	1·1 metres (3 ft. 7 5/16 in.).	1·4 metres (4 ft. 7 1/8 in.).
40 metres (2 chains).	1·5 metres (4 ft. 11 in.).	1·8 metres (5 ft. 10 7/8 in.).
50 metres (2 1/2 chains).	1·6 metres (5 ft. 3 in.).	2·0 metres (6 ft. 6 3/4 in.).
75 metres (3 3/4 chains).	2·0 metres (6 ft. 6 3/4 in.).	2·5 metres (8 ft. 2 7/16 in.).
100 metres (5 chains).	2·3 metres (7 ft. 6 9/16 in.).	2·9 metres (9 ft. 6 3/16 in.).
125 metres (6 1/4 chains).	2·6 metres (8 ft. 6 3/8 in.).	3·3 metres (10 ft. 10 in.).
150 metres (7 1/2 chains).	2·9 metres (9 ft. 6 3/16 in.).	3·6 metres (11 ft. 9 3/4 in.).
180 metres (9 chains).	3·2 metres (10 ft. 6 in.).	3·9 metres (12 ft. 9 9/16 in.).
210 metres (10 1/2 chains).	3·5 metres (11 ft. 5 13/16 in.).	4·3 metres (14 ft. 1 5/16 in.).

As regards the first, paragraph 51 states :

As regards locomotives with wheelbases exceeding the limits specified in paragraph 50, it is recommended to use bogies or radially-adjustable axles.

As far as can be gathered from the information received in answer to our list

of questions, the maximum wheelbases recommended by the German *Verein* for locomotives have been exceeded in a rather considerable number of cases; on the other hand, the wheelbases specified were not usually exceeded without having at least one or two of the coupled axles radially adjustable, or having one or two pairs of the coupled wheels made without flanges.

Accordingly, when the wheelbase dimensions given above are exceeded, it is in the first place advisable to use adjustable coupled axles, and if this does not suffice, the use of special motor bogies is then to be recommended.

I think I have now given a summary of all the points I consider of importance as regards the general features of the locomotives.

The President. (In French.) — Then kindly read out your conclusions.

Mr. Jesser. (In German.) — In giving a summary of my conclusions, I have intercalated explanations in the text of my conclusions, without reading them out on end. The conclusions which I recommend for adoption are given at the end of my report. I will now read them out, at the request of the President.

Locomotives suited to the character of the line and of the traffic on narrow-gauge railways.

A. — *The design of new narrow-gauge lines which are to be operated with steam locomotives, are to be used for public traffic, and have to deal with a considerable amount of passenger or goods traffic.*

1° In all the cases in which the selection of the gauge of a new line is not decided in advance by its immediate junction with another line or by some other administrative connection with an existing narrow-gauge system, a gauge of 1 metre (3 ft. 3 3/8 in.) is considered the best. A smaller gauge than 600 millimetres (1 ft. 11 5/8 in.), and the selection of a new gauge which does not yet exist, are not to be recommended;

2° In the case of adhesion lines, whose locomotives work without any artificial increase of friction, it appears as a rule advisable not to have steeper gradients than 40 per mil;

3° It is recommended as a rule not to have curves with a radius of less than 40 metres (2 chains), if the vehicles are not specially designed for sharper curves. It is desirable to have the straights between the super-elevation gradients of reverse curves, which are not equipped with guard rails, not shorter than the greatest existing distance between the bogies of a vehicle;

4° If a busy traffic has to be dealt with, it appears advisable to build the road and road-bed of a line having a gauge of 1 metre (3 ft. 3 3/8 in.), of such a strength that it can stand an axle-load of 10 tons (9·84 English tons); it is recommended, particularly in the case of lines with steep gradients and sharp curves, to provide for greater axle-loads.

B. — *As regards the design of new locomotives.*

1° The following may be recommended *in order to increase the power of locomotives:*

a) The use of a *working pressure* of up to 14 atmospheres;

b) *Superheating the steam* to 300° C. (572° Fahr.);

c) *Compounding.*

2° On lines on which the following curves frequently occur on the open line, no greater

rigid wheelbases should be used than those given in the following table :

RADIUS OF CURVE.	RIGID WHEELBASE.
25 metres (1 1/4 chains).	1·4 metres (4 ft. 7 1/8 in.).
40 metres (2 chains).	1·8 metres (5 ft. 10 7/8 in.).
50 metres (2 1/2 chains).	2·0 metres (6 ft. 6 3/4 in.).
75 metres (3 3/4 chains).	2·5 metres (8 ft. 2 7/16 in.).
100 metres (5 chains).	2·9 metres (9 ft. 6 3/16 in.).
125 metres (6 1/4 chains).	3·3 metres (10 ft. 10 in.).
150 metres (7 1/2 chains).	3·6 metres (11 ft. 9 3/4 in.).
180 metres (9 chains).	3·9 metres (12 ft. 9 9/16 in.).

If the adhesive weight necessary cannot be obtained inside the limits set by these wheelbases and the admissible maximum axle-loads, then, according to the excess required, the following arrangements can be recommended :

a) *Lateral play ;*

b) *Not having flanges* on some of the pairs of coupled wheels ; if these measures do not suffice, then ;

c) *Having some of the coupled axles radially adjustable* ; and finally,

d) *The use of one or two motor bogies movable relatively to the main frame*, with mechanical transmission from one main steam engine or each with a separate steam engine.

Mr. Weiler, ministry of public works, Siam. (In German.) — In talking of the design of the locomotives, the reporter has considered the influence of the line, that is to say the curves, the gradients and the gauge of the line. I ask whether it is not also desirable to mention the influence of the maximum moving dimensions, the loading gauge. The more room the designer has available, the easier it is to succeed in obtaining powerful engines.

In Prussia, the State prescribes exactly the same standard loading gauge for tracks with gauges of 60 and of 75 centimetres (1 ft. 11 5/8 in. to 2 ft. 5 1/2 in.). That seems illogical. It seems to me that the 75-centimetre (2-ft. 5 1/2-in.) track should have a larger loading gauge. I do not know what is done in this way in other countries. But it would be interesting to examine generally the influence of the standard loading gauge on these types. It is certainly possible to design, for a smaller loading gauge, a locomotive having the same power as one for a larger loading gauge, but the design will be more complicated and more expensive. Consequently, it would probably be necessary to know also the cost of the locomotives in order to make a comparison, for it is exactly on narrow-gauge lines that this question is of importance. That is what I wished to remark.

Mr. Jesser, *reporter*. (In German.) — I have certainly thought of this. According to what I know of the conditions existing in the countries which I know, the State has fixed *a priori* the loading gauges for tracks of each gauge, and exceptions must be rare. Consequently, I thought it useless to investigate what locomotives could be put in use on narrow-gauge lines with larger loading gauges, because it seemed to me improbable that the government would authorize the use of a greater loading

gauge than that now specified. The point may be important in countries in which regulations of this kind do not yet exist. But I have not considered it from this point of view, I have taken the loading gauges such as they exist.

The President. (In German.) — The president of the 2nd section asks us to join that section where motor cars are going to be discussed. He thinks it very important that we should take part in the discussion of this question which is closely related in sundry respects with that of the locomotives. I think that we ought to accept that invitation. (*Approval.*)

— The meeting adjourned at 10 a. m.

Meeting held 6 July 1910 (afternoon).

—

MR. VON ZIFFER, VICE-PRESIDENT IN THE CHAIR.

The President. (In French.) — I declare the meeting opened. We will resume the discussion of question XIX.

Does anybody else wish to speak?

Mr. de Burlet, *vice-president.* (In French.) — I wish to obtain some information from the honourable reporter.

On page 47 of his report (1) he states that on adhesion lines there are gradients of 5·88, 70 and 82·5 per mil. That seems to me tremendous. Can he perhaps tell us on what lines these gradients exist, operated by simple adhesion locomotives, and whether there is also a goods service on these lines?

Mr. Jesser. (In French.) — These gradients are on an American line, having a gauge of 914 millimetres (3 feet).

This line is chiefly used for the carriage of goods, of minerals.

Mr. de Burlet. (In French.) — That seems extraordinary! It is probable that the heavy traffic is in the downhill direction. One cannot explain it in any other way.

Mr. Jesser. (In French.) — The locomotives are very powerful.

Mr. de Burlet. (In French.) — They probably also have special brakes.

Mr. Jesser. (In French.) — 500 horse-power.

Mr. de Burlet. (In French.) — Many thanks for this information.

Mr. Jesser. (In French.) — You will find more detailed information about this subject in the appendix.

Mr. de Burlet. (In French.) — Another figure has struck me. On page 48, 2d column, speeds of 50 and 65 kilometres (31 and 40·4 miles) per hour are mentioned. These two numbers seem to me excedingly high for secondary lines. There are few countries where such speeds are authorized by the rules in force.

Mr. Jesser. (In French.) — In Sweden we find, for a gauge of 890 millimetres

(1) See also *Bulletin of the Railway Congress*, 1910, July, p. 3163.

(2 ft. 11 3/64 in.), curves having radii of 150 metres (7 1/2 chains), and maximum speeds of 50 (31 miles), and then of 57 kilometres (35·4 miles) per hour.

Mr. de Burlet. (In French.) — Then one is authorized to run at speeds twice to three times those allowed elsewhere, particularly in Belgium, where we are not allowed to run at more than 30 kilometres (18·6 miles) per hour in the country...

The President. (In French.) — In Austria, 40 kilometres (24·8 miles) per hour.

Mr. de Burlet. (In French.) — ... and at more than 10 to 12 kilometres (6·2 to 7·5 miles), according to circumstances, in populous places.

Mr. Chassin, French Southern Railway. (In French.) — In France, the speed on narrow-gauge lines can attain 40 kilometres (24·8 miles) per hour; that is so on the French Southern Railway, in particular.

We have gradients of 30 per mil and curves with a minimum radius of 150 metres (7 1/2 chains). In order to operate these lines, we have locomotives with three coupled axles and leading bogie, and Mallet locomotives for goods.

The line from Nice to Digne, to be opened in 1911, length 150 kilometres (93 miles), with gradients of 30 per mil, will have express trains attaining a speed of 45 kilometres (28 miles) per hour.

Mr. de Burlet. (In French.) — Those lines are laid, are they not, on a road-bed of their own?

Mr. Chassin. (In French.) — Naturally. I am speaking of secondary lines having a gauge of 1 metre (3 ft. 3 3/8 in).

35 to 40 kilometres (21·7 to 24·8 miles) per hour are ordinary speeds.

Mr. de Burlet. (In French.) — Are there level crossings which are not guarded?

Mr. Chassin. (In French.) — Some are guarded, others are not.

Mr. de Burlet. (In French.) — Even with such speeds, there are level crossings which are not guarded?

Mr. Chassin. (In French.) — Certainly, but there are notice-boards cautioning the public to look out before crossing the line, and giving the times at which trains are due to pass.

The President. (In French.) — In Austria, we have the speed of 40 kilometres (24·8 miles) per hour, and we also have level crossings which are not guarded.

Mr. Francis Level, Anvin-Calais Railway. (In French.) — In France, regulations as to speed are only made for lines laid on public highways.

Mr. Girtanner, Federal department of posts, and railways, Switzerland. (In German.) — In Switzerland, the speed on narrow-gauge lines is fixed by an order of the Federal Council dated 10 March 1906; it varies between 45 kilometres (28 miles) per hour as maximum for trains equipped with the continuous brake, and with gradients attaining 15 per mil, and 18 kilometres (11·2 miles) per hour for trains without continuous brake, with gradients attaining 70 per mil and curves with a radius of less than 60 metres (3 chains), with a minimum of 40 metres (2 chains). These rules apply to lines on an independent road-bed. The speed is much less on the lines laid on public high-

ways. In such cases, it must not exceed 12 kilometres (7·5 miles) per hour when passing through populous places, in the narrow streets of towns and villages, in order to attain its maximum of 25 kilometres (15·5 miles) per hour in the open country, between the populous places. In considering these figures, it must not be forgotten that these speeds must be reduced still further, in accordance with the gradients, in the open country : on gradients of over 30 and up to 50 per mil, it must not exceed 20 kilometres (12·4 miles) per hour; up to 70 per mil, 15 kilometres (9·3 miles) per hour; up to 90 per mil, 12 kilometres (7·5 miles) per hour; over 90 per mil, 8 kilometres (5 miles) per hour. On curves having a radius of less than 75 metres (3 $^{3}/_{4}$ chains), the maximum speed must in no case exceed 20 kilometres (12·4 miles) per hour. Thus there is a considerable reduction of speed here.

Mr. de Burlet. (In French.) — That is nearly the same as with us.

Mr. Ch. Masson, Visp-Zermatt Railway, Switzerland. (In French.) — However these speeds are considerably reduced, according to gradient, to 12 and 8 kilometres (to 7·5 and 5 miles) per hour.

The President. (In French.) — Does anybody else wish to speak?

We will now discuss and vote the conclusions.

This is the first clause :

" **Locomotive suited to the character of the line and of the traffic on narrow-gauge railways.**

" A. — *The design of new narrow-gauge lines which are to be operated with steam locomotives, are to be used for public traffic, and have to deal with a considerable amount of passenger or goods traffic.*

" 1° In all the cases in which the selection of the gauge of a new line is not decided in advance by its immediate junction with another line or by some other administrative connection with an existing narrow-gauge system, a gauge of 1 metre (3 ft. 3 $^{3}/_{8}$ in.) is considered the best. A smaller gauge than 600 millimetres (1 ft. 11 $^{5}/_{8}$ in.), and the selection of a new gauge which does not yet exist, are not to be recommended."

— Adopted.

" 2° In the case of adhesion lines, whose locomotives work without any artificial increase of friction, it appears as a rule advisable not to have steeper gradients than 40 per mil."

Mr. George Level, General Light Railway Company, France. (In French.) — 40 per mil, that seems to me rather excessive.

Mr. Jesser, *reporter*. (In French.) — Do you wish to increase it?

Mr. de Burlet. (In French.) — No, no!

The wording runs : " It appears as a rule advisable... " Thus it is a qualification. Further qualification is unnecessary.

— Clause 2 is adopted.

The President. (In French.) — " 3° It is recommended as a rule not to have curves with a radius of less than 40 metres (2 chains), if the vehicles are not specially designed for sharper curves. It is desirable to have the straights between the super-elevation gradients of reverse curves, which

are not equipped with guard rails, not shorter than the greatest existing distance between the bogies of a vehicle."

Mr. Schaetz, *secretary-reporter*. (In French.) — As regards curves having a radius of 40 metres (2 chains), I wish to state that in my opinion a higher figure should be recommended as minimum limit. We here must represent the point of view of operation rather than that of construction. The constructor already has sufficient inducement to reduce the radii of the curves in order to reduce the cost of construction of the line.

Working expenses are never sufficiently considered in scheming new railway lines and there is too much tendency to calculate the cost of construction only. Sharp curves cause quick wear of the tires and the rails, and working very soon becomes expensive.

It is stated that « it is recommended as a rule not to have curves with a radius of less than 40 metres (2 chains), if the vehicles are not specially designed for sharper curves. » The locomotives must be constructed to suit the tracks, and not the tracks to suit the locomotives which are not yet built.

The proposed wording seems to me rather illogical. We cannot, however, recommend such a low limit for the radius of curves, solely in order to utilize vehicles which can round run sharp curves. There is, on the contrary, every advantage, even if such vehicles have to be used, to have lines which only have sharp curves at the points where this is absolutely necessary.

Naturally there are cases where existing rolling stock must run on new branches; but as a rule, it is new rolling stock which runs on a new line.

I propose to say : " and not to go below this limit except when it is absolutely necessary, at certain points, to have sharper curves put in."

On the other hand, the wording proposed would seem to recommend that all lines should have curves with radii of 40 metres (2 chains). I think that we should not go below 80 metres (4 chains).

Mr. George Level. (In French.) — I ask that the minimum radius should be fixed at about 80 to 90 metres (4 to $4\,^1/_2$ chains).

Mr. Jesser. (In French.) — I took 40 metres (2 chains) as minimum, because among the locomotives about which I received information, there are many which can negociate such curves without much difficulty. You will find information about this on page 68 of my report (1).

The President. (In French.) — Do you propose anything, M. Schaetz?

Mr. Schaetz. (In French.) — I uphold my original opinion. One can very well build, without much trouble, lines with no curves of smaller radius than 80 metres (4 chains). If one goes as low as 40 metres (2 chains), this must only be in case of necessity, for instance in order to avoid having to build expensive constructive works.

Mr. de Burlet. (In French.) — Is it necessary to name a figure? The radius of the curves is so closely connected with the local topographical conditions and they vary widely from one district to another.

(1) See also *Bulletin of the Railway Congress*, 1910, July, p. 3184.

Mr. Chassin. (In French.) — As a rule, it is better to have curves with a radius of at least 80 metres (4 chains). They give much better running, and the wagons and the locomotives can have longer wheelbases. It has to be noted that when there are curves with a radius of 40 (2 chains) or even 60 metres (3 chains) on the open line, the outer rails and the flanges of the wheels become worn extraordinarily quickly.

Besides, there is no question of an injunction, but merely of a recommendation.

Mr. de Burlet. (In French.) — In my opinion, the laying out of the lines should be such as to give the curves as large radii as possible. It is clear that there are greater difficulties in traction and real troubles in the case of lines with sharp curves ; a material increase in the working expenses results. If then one goes as low as 40 metres (2 chains), it is because it is impossible to do otherwise except by spending excessive sums on the construction of the lines ; but, on the other hand, there is a certain danger in fixing a minimum of 80 metres (4 chains) as a general rule. If that figure is given, it may give trouble at a given moment. If an administration proposes a scheme with curves of 50 or 60 metre (2 $^1/_2$ or 3 chains) radius, it will be told : you must not go below 80 metres (4 chains) ; this figure has been fixed by the International Railway Congress, with all the authority attached to its decisions. That is why I think it is better not to give a definite figure.

Mr. Schaetz. (In French.) — What has struck me in the proposed text, is the figure of 40 metres (2 chains) recommended as a lower limit. One can easily gather from the present discussion the limit which seems most suitable, and I am of opinion that no figure should be given in the proposals of the section.

Mr. de Burlet. (In French.) — Just as there is a disadvantage in fixing 40 metres (2 chains) as a limit, so there is another in fixing 80 metres (4 chains) as a limit. Let us simply record our general opinion, I think unanimous opinion, that in planning the line the curves should be given as large radii as reasonably possible.

Mr. Jesser. (In German.) — I venture to remark that the German *Verein*, which as we know specifies very strict conditions, has prescribed a minimum radius of 40 metres (2 chains) for lines having a gauge of 750 millimetres (2 ft. 5 $^1/_2$ in.). I think that the Congress of the railways of the whole world should not be more strict than the German *Verein*, especially as, as has already been stated, the table includes a number of rather sharp curves, and as locomotives with six coupled wheels run without trouble over curves having radii of 40 (2 chains), and even of 25 metres (1 $^1/_4$ chains). It must finally be remembered, that according to the further prescriptions, rigid wheelbases, with axles not radial at all, are admissible up to 1·5 metres (4 ft. 11 in.) for locomotives and up to 1·8 metres (5 ft. 11 in.) for vehicles. These wheelbases suffice perfectly for an ordinary locomotive with three coupled axles which is not called upon to do any exceptional work. If greater power is to be obtained (and in Austria they have succeeded in obtaining nearly 300 horsepower), this can be done by using carrying axles. It is true that locomotives of

this kind cannot be expected to give a big tractive effort. However, a whole series of types have been mentioned which also satisfy the latter condition. The simplest system is the Klien-Lindner system which makes it possible to use Locomotives with four coupled axles on curves of such radii. I certainly think that no permament-way engineer who goes to the conclusions of the Congress for guidance will be able to conclude that he must everywhere use curves having a radius of 40 metres (2 chains) as soon as there is some small obstacle. But he must be able to go down to 40 metres (2 chains) if he is in a ravine or on the steep flanks of a mountain and if a crossing involves a long viaduct or bridge.

That is how I understand the matter. It is very possible that I have not succeeded in making the text as clear as it should be; but owing to the concise wording that the conclusion should have, it is very difficult to express all ideas. I only desired to recapitulate them, and I leave it to the section now to come to the necessary decisions.

Mr. Weiler. (In German.) — I think that the first clause, which states that a gauge of 1 metre (3 ft. 3 3/8 in.) is to be preferred to a smaller gauge, already expresses the idea that smaller radii are also tolerated. In fact, the reporter specially mentions that locomotives can now be constructed in such a way as to be able to run round the sharpest curves. Consequently, it is no longer necessary to select a smaller gauge. If it is desired to increase the radius, then the first clause should be struck out; one cannot stand without the other. But I believe that many administrations of minor lines are anxious, as you have already been told, not to have too small radii.

I have been told that the Otavi line, which has a gauge of 60 centimetres (1 ft. 11 5/8 in.) and a length of 600 kilometres (373 miles), is now having the radii of its curves increased because large radii are preferred, with a view to the maintenance of the track and of the rolling stock; and it is thought preferable to incur a certain expenditure for this purpose.

Mr. C. Sapin, Côtes-du-Nord Railway, France. (In French.) — I ask, as a tendency towards leasing has been shown, that it should not be made possible for future railway owners to compel us to operate under onerous conditions. We must try to operate as cheaply as possible, and is that why when schemes for building narrow-gauge lines are being worked out, it is above all necessary to consider the ease and economy of the working; it is above all necessary not to sacrifice these elements to considerations of economy in prime cost.

I think it would be preferable not to fix a figure.

Mr. Jesser. (In German.) — Perhaps it is possible to find an intermediate statement in order to meet all wishes. One can say that a minimum radius of 80 metres (4 chains), often mentioned, is recommended, but that this limit can be reduced to below 40 metres (2 chains) if the rolling stock is specially designed for running round such curves.

Mr. de Burlet. (In French.) — This is the wording I propose: " It is agreed to recommend that the line should be planned so as to have curves of as large a radius as possible. It is only in case of

absolute necessity that one can go far down to 40 metres (2 chains) as radius, unless the vehicles are specially equipped." (*Protests.*)

Mr. Chassin. (In French.) — Strike out the part about the vehicles; the rest is all right.

Mr. de Burlet. (In French.) — Very good. Accordingly we strike out the words: "unless the vehicles are specially equipped". In any case, the first part of the text seems to me to meet all wishes very well.

Mr. Francis Level. (In French.) — It is better to specify no figure.

Mr. de Burlet. (In French.) — It is said: "It is only in case of absolute necessity".

It seems to me that my wording is of a kind to satisfy everybody, but I clearly see that we are in the presence of a good number of operators (*Laughter*); however, the latter do not as a rule buy a pig in a poke, if I may use that slang phrase. When they apply for a working lease, they know the scheme, and they fix their conditions in accordance with the technical conditions under which the line is built or is going to be built; at least such is the case with us. We never arrange for the leasing of a line before the plans have been completed and even before the line is nearly finished. The lessee accordingly has full information; if there are curves with a radius of 40 or 50 metres (2 or 2 1/2 chains), he fixes his conditions accordingly.

My own conviction is that I have already gone very far in saying: "It is only in case of absolute necessity that one can go to 40 metres (2 chains)." I thus give lessees, who are defended very eloquently here, a satisfaction which should suffice, and I show that I am conciliatory.

You will be quite well enough equipped, gentlemen, to be able to dispute matters with the engineers of departments and to prove that there is no necessity, and even if there is necessity, you will maintain that it is not absolute, and perhaps you will be right.

The President. (In French.) — There seems to be agreement. (*Signs of approval.*)

Mr. de Burlet. (In French.) — We will try to find for the decisive text, an even more forcible expression.

The President. (In French.) — Thus we are agreed as to principle, subject to drafting clause 3 in such a way as to allow for the desiderata expressed.

We now pass to clause 4:

"4° If a busy traffic has to be dealt with, it appears advisable to build the road and road-bed of a line having a gauge of 1 metre (3 ft. 3 3/8 in.), of such a strength that it can stand an axle-load of 10 tons (9·84 English tons); it is recommended, particularly in the case of lines with steep gradients and sharp curves, to provide for greater axle-loads."

Mr. de Burlet. (In French.) — The last sentence does not seem to be quite clear. It states that this recommendation applies in particular to lines with steep gradients and sharp curves, that it is advisable to build for relatively heavier axle-loads. Would it not be better to say: "In the case of lines with steep gradients and sharp curves, it is advisable to build the tracks so as to suit axle-loads exceeding 10 tons?"

Mr. Jesser. (In French.) — We agree. The wording of this clause shall be modified accordingly.

— Adopted.

The President. (In French.) — This is the second part of the conclusions :

" B. — *As regards the design of new locomotives.*

" 1° The following may be recommended in order to increase the power of locomotives :

" *a*) The use of a working pressure of up to 14 atmospheres ;

" *b*) Superheating the steam to 300° C. (572° Fahr.) ;

" *c*) Compounding."

Mr. Chassin. (In French.) — Why is 300° C. (572° Fahr.) mentioned? I propose that no figure should be given.

Mr. Jesser. (In German.) — I thought that we ought not to recommend any greater superheat, for one knows that superheated steam strongly attacks sundry details of the locomotive, especially stuffing boxes and slide valves. I was of opinion that we ought to recommend only the superheat used up to the present without trouble by the administrations belonging to the Congress. It is quite possible that later on one may succeed in constructing stuffing boxes and slide valves, able to stand higher temperatures ; in particular, the tubes are exposed to temperatures appreciably higher than those attained by the steam. I consider any further increase in the temperature as an experiment for the future, and I think that superheating up to 300° C. (572° Fahr.) can readily be adopted. Everybody is free to make experiments about the limits to which it is possible to push superheating. I personally have watched superheating experiments made with stationary boilers. Temperatures of 320° and 330° C. (608° and 626° Fahr.) were reached, and things went very well. In my opinion it is prudent, in a way, to indicate a limit, so that those who are not familiar with the subject may not use too high temperatures, without knowing that they are exceeding the usual limit.

Mr. de Burlet. (In French.) — It is better to give no figure. One is still in the experimental period, particularly as regards secondary railways.

We have constructed and sent to the Brussels exhibition a locomotive of the superheating type for use on light railways.

Mr. C. Sapin. (In French.) — I am of opinion that it would be better to recommend the continuation of investigations, so as to make it possible later on to examine the results obtained, and to ascertain whether it is advisable to develop the use of compounding and of superheating.

Mr. Chassin. (In French.) — Let us not fix a figure.

Mr. de Burlet. (In French.) — We made trials during six months before sending the locomotive I have mentioned to the exhibition. I must say that we obtained good results and we have ordered a second locomotive of the same type ; but I repeat, we are still in the experimental period.

Mr. Jesser. (In German.) — I think the use of superheat up to this temperature can very well appear in our conclusion otherwise than as an experiment, as we know that the Swedish State Railway has been using such superheating since 1906,

without having found any objectionable effects. It would accordingly be wrong to say that it is but an experiment; I think, on the contrary, that up to a temperature of 300° C. (572° Fahr.) the question may be considered definitely solved and superheating applicable without other restrictions.

Mr. de Burlet. (In French.) — It would be preferable not to limit the experiments to this figure.

I think we agree that the phrase : " up to 300° C. (572° Fahr.) " should be struck out. (*Signs of approval.*)

— Clause 1 as amended is adopted.

The President. (In French.) — This is clause 2 :

" 2° On lines on which the following curves frequently occur on the open line, no greater rigid wheelbases should be used than those given in the following table :

RADIUS OF CURVE.	RIGID WHEELBASE.
25 metres (1 1/4 chains).	1·4 metres (4 ft. 7 1/8 in.).
40 metres (2 chains).	1·8 metres (5 ft. 10 7/8 in.).
50 metres (2 1/2 chains).	2·0 metres (6 ft. 6 3/4 in.).
75 metres (3 3/4 chains).	2·5 metres (8 ft. 2 7/16 in.).
100 metres (5 chains).	2·9 metres (9 ft. 6 3/16 in.).
125 metres (6 1/4 chains).	3·3 metres (10 ft. 10 in.).
150 metres (7 1/2 chains).	3·6 metres (11 ft. 9 3/4 in.).
180 metres (9 chains).	3·9 metres (12 ft. 9 9/16 in.).

Mr. de Burlet. (In French.) — These figures seem to me to be well established. I propose to accept them.

Mr. C. Sapin. (In French.) — I propose that the figure 25 (1 1/4 chains) should be struck out.

Mr. de Burlet. (In French.) — Yes, Mr. Operator, we will strike it out. (*Laughter.*) Those who have curves with radii of 25 metres (1 1/4 chains) can examine what wheelbase is suitable; that will be in better agreement with our discussion about the radii of curves.

— Clause 2 as amended is adopted.

Mr. de Burlet. (In French.) — We have to decide about the following clauses :

" If the adhesive weight necessary cannot be obtained inside the limits set by these wheelbases and the admissible maximum axle-loads, then, according to the excess required, the following arrangements can be recommended :

" *a*) Lateral play;

" *b*) Not having flanges on some of the pairs of coupled wheels; if these measures do not suffice, then;

" *c*) Having some of the coupled axles radially adjustable; and, finally;

" *d*) The use of one or two motor bogies movable relatively to the main frame, with mechanical transmission from one main steam engine or each with a separate steam engine."

That gives a choice between different measures; that commits nobody and cannot inconvenience any administration.

Mr. du Beaufret, Bône-Guelma Railway, Algiers. (In French.) — It seems that the word " bogie " is generally held to mean

that there are two axles. Now there are narrow-gauge locomotives with six axles. It would perhaps be better to say "truck".

Mr. de Burlet. (In French.) — That remark is quite corect.

— Adopted with this modification.

The President. (In French.) — We pass to the next section of the question :

" Is it advisable to protect the wheels and the moving parts by a metal cover? "

Mr. Jesser. (In German.) — The discussion of the chief question, that of the latest types of locomotives, which is from many points of view the most interesting and most important one, being now concluded, we pass to the supplementary questions, the first being whether *it is advisable to protect the wheels and the moving parts by a metal cover*.

Twenty-eight administrations sent answers to the list of questions; twelve of them limit themselves to the statement that they do not use such covers, although some of them operate lines which also use public highways. The sixteen other administrations give more or less detailed information, of which I will give a summary. The proportion of answers in the affirmative to answers in the negative is as 7 to 7. Such covers are considered useless by two administrations whose locomotives originally had covers which later on were removed, and by another administration which continues to use the covers. The lines of these three railways are in part on public highways. In one of these cases, it is stated that the fact that covers of the ordinary type are not really dust-proof, is the cause of the uselessness of the cover. In addition, there are four administrations which do not use covers, two which use public highways; these think that such covers are unnecessary.

Of the seven administrations which are in favour of covers or consider them useful six use this means of protection on their locomotives and one does not use it; two do not utilize public highways and one uses covers in order to economize in cost of lubrication and maintenance, as otherwise the dust whirled up from the ballast would have a deleterious influence on the mechanism.

It is evident that these contradictory opinions are not due merely to the varying importance attached by the different administrations to the advantages and disadvantages of the system, but chiefly to the different conditions of working. Besides the quantity of dust which has to be considered in each individual case, the physical properties of the dust, particularly the hardness of the material out of which it is formed and the size of its particles, play an important part.

These reasons make it impossible to give a general answer to the question; it will vary in each individual case, in accordance with the factors which come into play.

The answers received make it possible to draw the following general conclusion : the use of a cover for the wheels and the moving parts of the mechanism has as chief object the protection of the rubbing surfaces against foreign bodies, especially dust.

As secondary objects, it may be mentioned that such locomotives scare horses, whether driven or ridden, less and in cases of grazing vehicles or of collision with animals or persons, less damage is done.

On the other hand, the presence of coverings makes it more difficult to look after the engine, particularly at wayside stations with short stops, and care should be taken to design the coverings so as to provide for the easy accessibility of the mechanism.

If the locomotives are exposed to much dust consisting of hard particles the use of protective coverings is to be recommended and these, in order to be effective, must be as dust-proof as possible and enclose the whole mechanism.

Accordingly I have drafted the following text, which I propose to you as conclusion :

1° Locomotives which are liable to suffer from an unusual amount of dust, can have their moving parts protected by a covering, which is to enclose, as far as possible, all the moving parts, and is to be as dust-proof as possible. Doors are to be provided in this covering so as to make the moving parts as accessible as possible;

2° Such coverings may also help to some extent to prevent the scaring of draft animals and to reduce damage in cases of collision with other vehicles, animals and persons.

Mr. C. Sapin. (In French.) — The reporter states that he received seven answers in favour and seven answers against. Now, when I look at page 6 of the report (1), I find that forty-four administrations are mentioned. Accordingly thirty have refrained from answering. To sum it up, this proves that coverings for the mechanism are used by seven companies out of the forty-four which have answered.

Consequently, this question lacks actuality.

Dust is mentioned. Seeing that secondary railways are more and more adopting somewhat faster speeds, there is every reason that the driver should be able to see, while running, the exterior mechanism.

The question of scaring animals by the sight of the mechanism has been mooted; but that is now of little importance, for motor cars merit that reproach to a far greater degree than the railways on highways. Now that motor cars are overrunning the roads, the secondary railways can no longer be considered monsters. (*Laughter.*)

Let it therefore not be said that our railways are able to scare draught animals.

Mr. Ch. Masson. (In French.) — Then the second clause of the conclusion should be struck out?

Mr. de Burlet. (In French.) — That remark is well founded. I think that we agree to strike out clause 2. (*Signs of approval.*)

Clause 1 is adopted.

Mr. Jesser. (In German.) — The second supplementary question is that of knowing whether *it is advisable to have a footplate on each end of the locomotive.*

Twenty-four administrations have sent answers about this subject. Nineteen of them state that their locomotives have only one footplate, and thirteen of these express no opinion about the usefulness of this arrangement, while the six others state that the double footplate is unneces-

(1) See also *Bulletin of the Railway Congress*, 1910, July, p. 3122.

sary, considering their traffic conditions; one administration states that it is not to be recommended.

Thus there are five administrations who have given an answer in the affirmative.

The administration of the Bavarian State Railway has tank locomotives with two cabs, connected with a passage way round the locomotive; at each end there is a gangway by means of which the employees on the train can reach the locomotive, while it is running. Provided that the other regulations in connection with this point are duly observed, locomotives of this kind may be driven by one single man. This naturally reduces the cost of traction.

In the case of railways which utilize roads or streets where there are numerous cross-roads and where there is much traffic it appears necessary, according to expert opinion, to make provision to enable the driver to see not only his track a sufficient way ahead but also as much as possible the streets crossing that on which the track is laid. If it is desired to save the cost of building and of operating turntables, as well as the time necessary for turning locomotives, so that the cab may always be frontways while running, it is possible to have either a central raised cab in the case of tracks of short length, without large-capacity boilers, or two cabs, one at each end of the locomotive.

In the types, drawings of which were sent by a Belgian administration and a French administration, the operation of the regulator and of the reversing gear can be effected from each of the two cabs without much complication of levers and rods. This solution may be considered the best for the object aimed at, as it enables the driver to have a good view of the street traffic.

A very noteworthy similar solution is reported to us by the Great Western Railway (England); strictly speaking it does not fall within the scope of this question, but nevertheless it has a similar object in view. It is intended for use on a standard-gauge line having its own road-bed, but can also by applied without modification to a narrow-gauge line; hence I mention it here. A train consisting of two carriages and a tank locomotive is coupled up permanently so as to be able to run in either direction, the locomotive always remaining between the two carriages. A mechanical rod and lever transmission makes it possible to operate the regulator from either of the two cabs which are at the two ends of the train, each of the carriages having a cab or driver's compartment at one end. While running, the driver is in that cab which is at the head of the train, and the fireman is on the locomotive. There is no provision for passing from the carriages to the locomotive while the train is running; the employees on the train communicate with each other by means of whistle and bell signals. This arrangement makes it possible for the driver to have a perfectly clear view of the track and makes it unnecessary to turn the locomotive to shift it to the head of the train; hence it seems suitable, in the case of a shuttle service on short lines where the direction of running is frequently reversed, for it saves not only the time which would be required for shunting operations, but also the station line which would have had to be kept clear, then becomes available for other purposes.

We now can pass to the conclusions which naturally fall into three divisions and which run as follows :

1° In the case of lines which use streets in thickly-populated towns with much traffic, it is advisable to arrange matters, so that the driver can in good time obtain an unobstructed view of any side streets crossing the line.

If it is not possible always to turn the locomotives so as to be head on, it is advisable to have a cab at each end of the locomotive; it must be possible to operate the regulator and the cut-off from each cab, and to give the necessary signals.

Tractors with a raised cab, from which an unobstructed view can be obtained in every direction, satisfy this requirement without any need for turning them;

2° If the locomotive crew is to consist of one man only, it must be possible to pass from the train to the locomotive while running; this can be effected in the case of tank locomotives by having two footplates with gangway connections. Only one of the footplates need be equipped for driving;

3° In the case of a shuttle service with a train of two carriages running on its own road-bed the locomotive can be placed in the middle, if it is possible to operate at least the regulator and the brakes from the carriage-cabs at the ends of the train.

Mr. du Beaufret. (In French.) — The wording of clause 1 is too absolute. To lay down the principle that the driver must watch the cross streets, means stopping the railway. The train must be able to continue its journey.

Mr. Jesser. (In German.) — I think that the French text does not exactly represent the meaning of our wording. No doubt it is more difficult to make a good translation than is generally thought. I said in German : " Für Bahnen, welche Strassennetze in verbauten Ortschaften mit dichtem Verkehre benützen, " and it is perhaps possible to translate this more accurately into French than by the phrase here given : " Dans des rues..."

Let us consider our tracks in many towns, where one is often compelled to pass through streets which are so narrow that there is barely room for a street vehicle and a tramway. Side streets cross this street, and through them cabs and large carts arrive at a trot. It will be impossible to avoid accidents, if the driver cannot stop within a short distance, in other words, if he does not see in good time the vehicles which are crossing. I request those of my colleagues who know French better than I do, to select a phrase which will clearly express the idea I have just explained.

Mr. du Beaufret. (In French.) — It is a question of the wording. I do not claim that the driver should not look out for what happens at crossings.

Mr. de Burlet. (In French.) — It is said that : " it is *advisable* to arrange matters, so that the driver can in good time obtain an unobstructed view of any side streets crossing the line. "

It seems, according to this text, that he is not *obliged* to watch the streets he passes. Evidently nobody has this idea, and in order to make the meaning more clear, I propose to say : " It is advisable that the driver should have a free view of of the track, particularly where streets cross. "

He must evidently look out everywhere but especially so where streets cross.

Mr. du Beaufret. (In French.) — Quite so.

Mr. de Burlet. (In French.) — When one says " streets " that means populous places. (*Signs of approval.*)

Mr. C. Sapin. (In French.) — As for the cabs...

A delegate. (In French.) — We are at clause 1. What is decided?

Mr. C. Sapin. (In French.) — ... the French railways use double cabs very little. The presence of the driver in front can be useful if the railway uses the public highway over the greater part of its length; but if it only uses it exceptionally, the case is not the same. For instance, if a railway runs for 1 kilometre (0·62 mile) through a town where there is much traffic, out of a total length of 100 kilometres (62 miles), then it is not necessary to have two cabs.

Mr. de Burlet. (In French.) — You allow danger to continue on one part of the line when you know that it exists!

Mr. C. Sapin. (In French.) — But if it is an exception?

Mr. de Burlet. (In French.) — No matter! Where danger exists, even if concentrated at one short part of the line, the necessary precautions must be taken. On our railway system, I do not wish the driver to be at the back at any point whatever.

Mr. C. Sapin. (In French.) — You assume the railway constitutes a danger; but taking the progress of road locomotion into consideration, it is no more a danger than a tramway or a motor car.

Mr. de Burlet (In French.) — The railway is a danger, like a motor car. All those who drive a locomotive, a motor car, any vehicle, even those who drive horses, have to exercise particular care. I do not assert that the danger is so great that railways, motor cars, carriages, etc. should not be allowed to circulate in the streets, but these means of locomotion in the streets necessitate special precautions, and one of these is that the driver or watchman should be at the head of the train. If he is behind, it is impossible for him to see what happens on the rails. His line of sight only extends horizontally. Should a child be on the track, he cannot see it in good time and an accident necessarily happens. I have often intentionally travelled in locomotive cabs, in front and behind, when passing through villages or towns, in order to become fully acquainted with the subject. After the personal experience which I have acquired, I would not take the responsibility of authorizing the driver to be at the back of the locomotive! I do not admit that because no danger exists on the greater part of the run, therefore the precautions necessary should not be taken where the danger exists.

I therefore would urge that the wording proposed by our distinguished reporter, Mr. Jesser, should be adopted.

Mr. Jesser. (In German.) — I also think that it would be very easy to avoid the case the former speaker has mentioned. On a line which has long sections on public highways and which passes through a town, it must always be possible to turn the locomotive at the terminus, so that the driver is again in front. It is only in the case of lines where the density of the traffic is such that there is no time to turn

the locomotive, on those, for instance, which run through a town, that it is necessary for the driver to be in the cab in front. If the locomotive can be turned, it is unnecessary to have a second cab. But one or the other arrangement is indispensable.

M. de Burlet. (In French.) — Do you insist, Mr. Sapin?

Mr. C. Sapin. (In French.) — You say that there is danger. Our public administrations in France take every precaution necessary from this point of view. Thus in the Haute-Saône, two-cab locomotives are used on the first railway system. On the second system, they are not used, as it was thought better to leave the driver at the back ; but safety was provided for by reducing the speed accordingly. Thus there are speeds of 6 kilometres (3·7 miles) per hour. With his brakes the driver, even at the back, can at once stop his engine.

Mr. de Burlet. (In French.) — At the back, he does not see what happens in front of his engine.

Mr. C. Sapin. (In French.) — To recommend the double cab would be a disadvantage which would be recognized later on.

Mr. Jesser. (In French.) — We turn the locomotive; then the driver is in front.

Mr. C. Sapin. (In French.) — Then it is permanently running backwards!

Mr. Jesser. (In French.) — During half the mileage of the locomotive.

Mr. C. Sapin. (In French.) — You must always return with the back in front.

Mr. Jesser. (In French.) — That does not matter.

Mr. C. Sapin. (In French.) — Your driver is very badly placed.

Mr. Jesser. (In French.) — I have often done this; it is very easy.

Mr. C. Sapin. (In French.) — Let us say : "It is to be advised." The text is too absolute.

Mr. de Burlet. (In French.) — I see nothing to change in the text.

Mr. C. Sapin. (In French.) — Do we agree in principle?

Mr. de Burlet. (In French.) — It is a question of degree. Much money has been spent in equipping the vehicles with continuous brakes. Now the first condition necessary to make them effective, is that the driver who is to work those brakes should be able to see the rails and at once perceive any obstacle which may turn up. That is only possible if he is in front. I repeat and assert it as a fact that the driver, if at the back, cannot see the rails in front of his engine properly, at those points where an unexpected danger may turn up at any moment.

Mr. Philippe, Belgian Northern Railway. (In French.) — By doing away with the front cab, you shorten the length of the engine and you improve the outlook of the driver. If you place the driver and the fireman in the same cab at the back, they can both help in the watching of the track. In the case of engines with two cabs, although the driver can see better, the fireman cannot see so well. That seems to me to be worth mentioning. On

the other hand, as regards the management of the fire and of the boiler, do you not think that in certain cases there may be a serious disadvantage in separating the fireman from his driver, who is more skilful than he is?

There are instances which I wish I had time to mention as supporting Mr. Sapin's views.

To sum up, it is advisable not to be too absolute in the conclusions.

Mr. C. Sapin. (In French.) — Why not try to work out a design for a steam locomotive of the kind similar to electric locomotives, that is to say, one in which the driver and the fireman are always in front? That question can be solved without complications. Nothing compels us to have the fire always at the back ot the locomotive.

Mr. de Burlet. (In French.) — We cannot put this into a conclusion.

Mr. Philippe. (In French.) — The question of the driver has been settled on standard-gauge railways. There are locomotives on which the driver has two sets of driving appliances at his disposal. Thus he always has, ready to hand, whether running in one direction or the other, his regulator, his reversing gear and his brake.

Mr. du Beaufret. (In French.) — One could say : " it is advisable..."

The words : " it must be possible..." are too absolute.

Mr. de Burlet. (In French) — Do you agree, Mr. Reporter?

Mr. Jesser. (In French.) — Perfectly. One could find another phrase.

Mr. de Burlet. (In French.) — Do you recommend that the locomotive crew is to consist of a single man?

Mr. Jesser. (In French.) — Yes.

Mr. de Burlet. (In French.) — I do not!

Mr. Jesser. (In French.) — It is to be recommended that it should be possible for the train men to pass from the carriages to the locomotive while the train is running.

Mr. de Burlet. (In French.) — When will they reach it? When the accident has happened?

Mr. Jesser. (In French.) — When the driver gives a signal, for instance by means of an electric bell.

Mr. de Burlet. (In French.) — Then no opinion is expressed as to whether it is advisable to have one man on the locomotive or two?

Mr. du Beaufret. (In French.) — Allowances must be made for particular cases.

Mr. de Burlet. (In French.) — In France, is it permissible to have a single man?

Mr. C. Sapin. (In French.) — The decrees provide that one can have but a single man, but when one asks the departmental administrations that this rule should be applied, they raise objections which, moreover, are often well-founded, I admit. It happens, however, sometimes that the second man does not render those services which justify his presence.

Mr. de Burlet. (In French.) — But he is on the locomotive with the driver. In my opinion, this is necessary for the safety.

Mr. Jesser. (In German.) — We could

say in clause 2 : " It is recommended that the locomotive should be accessible from the carriages while running." (*Signs of approval.*)

Clause 3 mentions the shuttle service of trains on an English railway, in the following terms :

In the case of a shuttle service with a train of two carriages running on its own road-bed, the locomotive can be placed in the middle, if it is possible to operate at least the regulator and the brakes from the carriage-cabs at the ends of the train.

I may remark that I have added the word " brake ", although the English company does not mention this; but it is quite possible after all, that that is the case.

As regards clause 3, it should run : " In the case of a shuttle service with a train of two carriages running on its own road-bed." (*Signs of approval.*)

Mr. de Burlet. (In French.) — So be it, for those who go in for this odd practice!

The President. (In French.) — There there is agreement?

Mr. de Burlet. (In French.) — It is accordingly understood that section III is adopted with the different modifications proposed; in other words, there is agreement as to principles, while modifications have to be made in the text from the point of view of the drafting.

Order motion.

Mr. Georges Level. (In French.) — I have requested you to return to the question of the 40 metres (2 chains).

Mr. de Burlet. (In French.) — Mr. Level has in fact asked the bureau to return to the wording of clause 3 on page 56 of the report (1). We think we have already made great concessions, but are going to add to them. The original wording ran : " It is recommended as a rule not to have curves with a radius of less than 40 metres (2 chains) ". We proposed to say : " It is agreed to recommend that the line should be planned so as to have curves of as large a radius as possible. It is only in case of absolute necessity that one can go down to 40 metres (2 chains) ".

These gentlemen desire that the figure of 40 metres should not be given. Could we not adopt the following wording :

" It is agreed to recommend that the line should be planned so as to avoid curves of small radius. These should only be used in cases of absolute necessity. "

We have thus pushed conciliation to its extreme limits.

Mr. Jesser. (In French.) — Then the figure of 25 metres (1 $^1/_4$ chains) should be retained.

Mr. C. Sapin. (In French.) — One could say : " In the case of sharp curves, the vehicles require special equipment. "

Mr. Lembourg, National Suburban Railway Company, Belgium. (In French.) — Mr. Jesser asks that under these circumstances the radius of 25 metres (1 $^1/_4$ chains) should be reinserted in the table.

Mr. de Burlet. (In French.) — Do we agree? (*Signs of approval.*)

The President. (In French.) — Then that shall be so.

(1) See also *Bulletin of the Railway Congress*, 1910, July, p. 3172.

Mr. de Burlet. (In French.) — This is how we can word the conclusions which are to be submitted to the general meeting.

" The selection of the locomotive types for a narrow-gauge line very materially depends on the technical conditions of the line in question, particularly as regards curves and gradients, and the loads to be carried. The two elements (track and rolling stock) cannot, however, be considered separately and independently. It is from this point of view that the following recommendations are made :

" A) *Track* :

" 1° In all the cases, in which the selection of the gauge of a new line is not decided either by its immediate junction with another narrow-gauge system or by some other administrative considerations, a gauge of 1 metre (3 ft. 3 3/8 in.) is considered the best. Neither a smaller gauge than 600 millimetres (1 ft. 11 5/8 in.), nor a new gauge which does not yet exist, is to be recommended.

" 2° In the case of adhesion lines, it appears as a rule advisable not to have steeper gradients than 40 per mil.

" 3° The line should be planned so as to have curves of as large a radius as possible ; it should be decided to have no sharp curves unless this is absolutely necessary, and in such cases it is desirable that the vehicles should be specially equipped for the purpose. If the straights between the superelevation gradients of reverse curves are not equipped with guard rails, it is advisable that those straights should be at least as long as the greatest existing distance between the bogie centres of a vehicle.

" 4° If a busy traffic has to be dealt with, it will be advisable to build the road and roadbed to carry a load of 10 tons per axle (line with a gauge of 1 metre [3 ft. 3 3/8 in.]); this figure of 10 tons must, however, be increased in the case of lines having steep gradients and sharp curves.

" B) *Locomotives :*

" 1° In order to increase the power of the locomotives, the following may be recommended : a higher working pressure (up to 14 atmospheres), superheating the steam, compounding ; these three methods can be utilized either separately or simultaneously.

" 2° On lines with many curves, it is recommended not to have greater rigid wheelbases than shown in the table below :

MINIMUM RADIUS OF CURVES.	MAXIMUM RIGID WHEELBASE.
25 metres (1 1/4 chains).	1·4 metres (4 ft. 7 1/8 in.).
40 metres (2 chains).	1·8 metres (5 ft. 10 7/8 in.).
50 metres (2 1/2 chains).	2·0 metres (6 ft. 6 3/4 in.).
75 metres (3 3/4 chains).	2·5 metres (8 ft. 2 7/16 in.).
100 metres (5 chains).	2·9 metres (9 ft. 6 3/16 in.).
125 metres (6 1/4 chains).	3·3 metres (10 ft. 10 in.).
150 metres (7 1/2 chains).	3·6 metres (11 ft. 9 3/4 in.).
180 metres (9 chains).	3·9 metres (12 ft. 9 9/16 in.).

" If the adhesive weight necessary cannot be obtained inside the limits set by

these wheelbases and the admissible maximum axle-loads, then lateral play and not having flanges on some of the pairs of coupled wheels can be recommended; if these measures do not suffice, then they can be replaced either by having some of the coupled axles radially adjustable, or by using one or two motor bogies movable relatively to the main frame, with mechanical transmission of power from one main steam engine, or with a separate steam engine to each truck.

" C) *Metal cover for the moving parts :*

" If the locomotives are liable to suffer from an unusual amount of dust, it is possible to protect the moving parts by a covering, which should be as complete and as dust-proof as possible. Doors are to be provided in this covering so as to give easy access to the moving parts.

" D) *Foot-plate at each end of the locomotive :*

" 1° In the case of lines which pass through districts where there is much traffic, it is advisable that the driver should have a good view of the track in front of the locomotive.

" If it is not possible always to turn the locomotives so as to be head on, it is advisable either to have a cab at each end of the locomotive (from which the regulator and the cut-off can be operated, and the necessary signals given), or to equip the locomotive with a single raised cab, from which a view of the track can be obtained in each direction.

" 2° In the case of lines where the locomotive crew can consist of one man only, it is advisable that the locomotives should be accessible from the carriages while running ; this can be effected in the case of tank locomotives, by having two foot-plates with gangway connections, for giving access to the carriages. With such an arrangement, only one of the foot-plates need be equipped for driving.

" 3° In the case of a shuttle service with a train of two carriages running on its own roadbed, the locomotive can be placed between the two carriages (this eliminates all shunting operations at the termini) provided that it is possible to operate, from the platforms which in the case of each carriage form the end of the train, at least the regulator and the brake. "

— Adopted.

Mr. de Burlet. (In French.) — Gentlemen, before concluding the meeting, we have to thank the honourable reporter who undertook an exceedingly conscientious, detailed and laborious piece of work, which must have taken him a long time. We must be grateful to him for the documents he has collected, by which, with rare skill, he has enabled us to profit. His excellent work will occupy a place of honour in the libraries of all those who are occupied with the difficult question of the locomotives used on secondary railways. (*Applause.*)

DISCUSSION AT THE GENERAL MEETING

Meeting held on 14 July 1910 (afternoon).

Mr. P. WEISSENBACH, president, in the chair.

General secretary : Mr. L. WEISSENBRUCH.

First assistant general secretary : Mr. MÜRSET.

Second assistant general secretary : Dr. A. BONZON.

Mr. de Burlet, *vice-president of the 5th section*, read the

Report of the 5th section.

(See *Journal de la huitième session*, No. 8, p. 5.)

" Mr. Jesser (*reporter*) stated that the subject he had to deal with included both the locomotives and the rolling stock of narrow-gauge railways. But owing to the great extension of his work which had resulted from the abundance of information supplied to him by the different administrations, he had been compelled to limit his investigation to the first part of the subject, namely to locomotives, and to leave it to the Congress to deal with the second part at a future session.

" After a summary account of the principal elements which characterized the chief types of tractors described in his report, Mr. Jesser proceeded to show that each of these types corresponded to particular conditions of the line (plan and profile) and of the traffic. Whenever one had been compelled, by the topographical nature of the country, to have curves of small radius and steep gradients, it had also been necessary, in the case of traffic sufficiently developed, to adopt special devices for the locomotives, sometimes complicated and difficult to maintain (high pressure in the boiler, superheating, compounding, flexible axles, motor bogies). Mr. Jesser described and analysed the recent prescriptions (1908) of the German *Verein* on the subject of these different devices.

" The meeting then considered in succession the different conclusions given in Mr. Jesser's report. Several delegates, more especially Mr. C. Sapin (*Côtes-du-*

Nord Railway, France) and Mr. Chassin (*French Southern Railway*), stated that it would be very desirable, in drawing up schemes for narrow-gauge lines, if one paid greater attention to ease and facility of operation, and sacrified these elements less to considerations of economy in construction. They remarked that in France the State regulations did not concern themselves with the speed of trains on lines which did not use the public roads; any improvement in the plan of the line thus made it possible to improve the service from the point of view of the time required for the journey.

" Mr. Girtanner (*Swiss government*) informed the meeting that in Switzerland the regulations concerning narrow-gauge lines specified maximum speeds which differed according to whether the lines had a special roadbed or were laid on public roads, whether the rolling stock was equipped with the continuous brake or not, etc. In passing through towns, in the case of narrow streets, this maximum was reduced to 12 kilometres (7·5 miles) per hour.

" Different remarks were then exchanged, more especially on the subjects of superheating, of the advantages and disadvantages of a metal cover for the moving parts, and of two foot-plates for each locomotive. As for covers, Mr. Sapin remarked that the argument mentioned by the reporter, that horses and cattle would be frightened by the moving parts, no longer was of much importance, as motor cars were far greater offenders in this way than any trains on the public roads. As for foot-plates, the partisans of the single foot-plate chiefly invoked, in support of their opinion, the advantage of a continual supervision of the fireman by the driver who had to make certain that his assistant attended properly to the fire and to the feed, whereas the partisans of the double foot-plate attached most importance to the safety of the public when the trains passed through towns. Finally the section decided to submit the following conclusions to the general meeting."

The President. — The following are the

CONCLUSIONS.

" The selection of the locomotive types " for a narrow-gauge line very materially " depends on the technical conditions of " the line in question, particularly as " regards curves and gradients, and the " loads to be carried. The two elements " (track and rolling stock) can not how- " ever be considered separately and inde- " pendently. It is from this point of " view that the following recommenda- " tions are made :

" A) *Track :*

" 1° In all the cases, in which the " selection of the gauge of a new line is " not decided either by its immediate " junction with another narrow-gauge " system or by some other administrative " considerations, a gauge of 1 metre (3 ft. " 3 3/8 in.) is considered the best. Neither " a smaller gauge than 600 millimetres " (1 ft. 11 5/8 in.), nor a new gauge " which does not yet exist, is to be re- " commended.

" 2° In the case of adhesion lines, " it appears as a rule advisable not " to have steeper gradients than 40 per " mil.

" 3° The line should be planned so as " to have curves of as large a radius as " possible; it should be decided to have " no sharp curves unless this is absolutely " necessary, and in such cases it is desir- " able that the vehicles should be spe- " cially equipped for the purpose. If the " straights between the superelevation " gradients of reverse curves are not " equipped with guard rails, it is advis- " able that those straights should be at " least as long as the greatest existing " distance between the bogie centres of a " vehicle.

" 4° If a busy traffic has to be dealt " with, it will be advisable to build the " road and roadbed to carry a load of " 10 tons per axle (line with a gauge of " 1 metre [3 ft. 3 3/8 in.]); this figure of " 10 tons must however be increased in " the case of lines having steep gradients " and sharp curves.

" B) *Locomotives :*

" 1° In order to increase the power of " the locomotives, the following may be " recommended : a higher working press- " ure (up to 14 atmospheres), superheat- " ing the steam, compounding; these " three methods can be utilized either " separately or simultaneously.

" 2° On lines with many curves [and " having a gauge of 1 metre (3 ft. " 3 3/8 in.)] (1), it is recommended not to " have greater rigid wheelbases than " shown in the table below :

MINIMUM RADIUS OF CURVES.	MAXIMUM RIGID WHEELBASE.
25 metres (1 1/4 chains).	1·4 metres (4 ft. 7 1/8 in.).
40 — 2 .	1·8 — (5 ft. 10 7/8 in.).
50 — 2 1/2 .	2·0 — (6 ft. 6 3/4 in.).
75 — 3 3/4 .	2·5 — (8 ft. 2 7/16 in.).
100 — 5 .	2·9 — (9 ft. 6 3/16 in.).
125 — 6 1/4 — .	3·3 — (10 ft. 10 in.).
150 — 7 1/2 — .	3·6 — (11 ft. 9 3/4 in.).
180 — 9 .	3·9 — (12 ft. 9 9/10 in.).

" If the adhesive weight necessary can " not be obtained inside the limits set by " these wheelbases and the admissible " maximum axle-loads, then lateral play " and not having flanges on some of the " pairs of coupled wheels can be recom- " mended; if these measures do not " suffice, then they can be replaced either " by having some of the coupled axles " radially adjustable, or by using one or " two motor bogies movable relatively to " the main frame, with mechanical trans- " mission of power from one main steam " engine, or with a separate steam engine " to each truck.

" C) *Metal cover for the moving* " *parts :*

" If the locomotives are liable to suffer " from an unusual amount of dust, it is " possible to protect the moving parts by " a covering, which should be as complete " and as dust-proof as possible. Doors " are to be provided in this covering " so as to give easy access to the moving " parts.

(1) The words in brackets were added in the final reading (see below).

" D) *Foot-plate at each end of the locomotive :*

" 1° In the case of lines which pass through districts where there is much traffic, it is advisable that the driver should have a good view of the track in front of the locomotive.

" If it is not possible always to turn the locomotives so as to be head on, it is advisable either to have a cab at each end of the locomotive (from which the regulator and the cut-off can be operated, and the necessary signals given), or to equip the locomotive with a single raised cab, from which a view of the track can be obtained in each direction.

" 2° In the case of lines where the locomotive crew can consist of one man only, it is advisable that the locomotives should be accessible from the carriages while running; this can be effected in the case of tank locomotives by having two foot-plates with gangway connections, for giving access to the carriages. With such an arrangement only one of the foot-plates need be equipped for driving.

" 3° In the case of a shuttle service with a train of two carriages running on its own roadbed, the locomotive can be placed between the two carriages (this eliminates all shunting operations at the termini) provided that it is possible to operate, from the platforms which in the case of each carriage form the end of the train, at least the regulator and the brake."

Mr. Greppi, Italian State Railway. (In French.) — The section, in its conclusions, recommends that for given radii certain rigid wheelbases should not be exceeded, but it does not mention the gauge. I think that these wheelbases are calculated for the gauge of 1 metre (3 ft. $3\ ^3/_8$ in.), but it is perhaps advisable to say so.

Mr. de Burlet. (In French.) — They in fact do refer to a gauge of 1 metre (3 ft. $3\ ^3/_8$ in.), and if the meeting agrees, we will add these words to the conclusions.

— The conclusions of the 5th section, with these words added : " and having a gauge of 1 metre (3 ft. $3\ ^3/_8$ in.) ", are adopted.

QUESTION XX

TRANSHIPMENT

Examination of the different systems adopted for the exchange of goods between lines of different gauges (transhipment at the same level, sunk or raised tracks, trucks for taking cars of another gauge, tracks with three or four lines of rails, etc.).

REPORT

By C. DE BURLET,

GENERAL INSPECTOR OF BRIDGES AND ROADS,

GENERAL MANAGER OF THE BELGIAN NATIONAL LIGHT RAILWAY COMPANY.

The examination of the methods employed for the transhipment of goods between lines of different gauge has already been made an object of the deliberations of the Railway Congress, notably in its third Session at Paris, in 1889.

The discussion which then took place had reference chiefly to the following systems :

1° *Transhipment at the same level;*
2° *Sunk or raised tracks;*
3° *Movable truck-bodies;*
4° *Carrying-trucks* (for taking cars of another gauge).

Of these systems, the second was found to be costly in installation, and obstructive; as regards movable truck-bodies, the opinion was formed that, whilst these gave good results where the traffic was regular and important, they were not a success for traffic of a varying character and coming in both directions.

Carrying-trucks make it possible to convey main-line wagons upon narrow-gauge lines; their employment is suitable, it was thought, for goods liable to suffer from transhipment; but it could only be recommended as an exceptional thing on account of the inconveniences of the system; establishment of sunk transhipment tracks, not only in the stations, but also in the yards of the manufacturers linked up with the latter; considerable dead weight to carry, necessitating an extra charge and thus rendering onerous the generalization of the system among all classes of traffic; difficulty of braking, etc.

*

The Congress adopted the following resolutions :

1° Certain exceptional circumstances may justify, either from the point of view of the reduction of expense, or from that of the diminution of damage, the establishment of special transhipment arrangements, as for example, where the question is one of the working of mines, collieries, etc., connected by narrow-gauge lines with the main railroads, or in other similar circumstances;

2° But apart from these exceptional cases, it agrees in recommending, as a general rule, the simplest and most straightforward method of transhipment from truck to truck upon lines placed at the same level.

The very slightly enhanced cost at which the transfer of goods can be effected under such conditions renders very rarely justifiable the expense and inconvenience of special installations or the employment of exceptional arrangements : sunk or raised tracks, movable truck-bodies, carrying-trucks;

3° The only system which might, perhaps, be usefully employed, as being of a simple character and not involving much expense, is that of raising the narrow-gauge track in such a way that the floors of its trucks are at the same level as those of the standard-gauge line.

In certain cases, it might be possible to ameliorate in this way, at a trifling cost, the conditions of the transhipment of goods from the narrow-gauge to the standard-gauge line.

If there is a particular reason for doing so, on account of the importance of the goods brought to the standard-gauge line, it might even be advisable to raise the narrow-gauge line further by means of a platform.

Nevertheless, even as regards special installations of quite a modest character, it is advisable to weigh well the advantages and disadvantages before having recourse to them;

4° The experience of the last four years fully confirms the opinion expressed at the Brussels Session of the Congress, that " transhipment is in no way an obstacle to the development of subsidiary narrow-gauge lines, or to the great services they are capable of rendering.

The *Permanent International Union of Tramways* has also been induced to consider the question of transhipment, first at its general session of 1890, at Amsterdam, and more recently at that of London in 1902, with reference to the best *choice to be made in the gauge of light railways.*

Having been reporter on this question at the London session, the author of the present article arrived at the following conclusion, with which the general meeting concurred :

" If matters are regarded in a practical light, and not from a speculative and theoretical point of view, it must be recognized that *transhipment* can be effected with facility, without injury to the goods, and at little cost.

" Various methods and mechanical means have been devised with a view to rendering transhipment easier, but all are complicated and costly; and our experience, very widely established and confirmed by the opinion of many other companies, has satisfied us that, upon the whole, the simplest and most economical method is transhipment from truck to

truck, the floors of the two vehicles being brought, if possible, to the same level, which result may be achieved by raising the narrow-gauge line.

" The very slight cost (15 to 20 centimes per ton [1·46*d.* to 1·95*d.* per English ton]) at which the handling of the goods in the process of transhipment can be effected, justifies only very exceptionally the installation of the special arrangements alluded to above, such as sunk or raised tracks, movable truck-bodies, carrying-trucks, etc. "

Mention might also be made of an interesting article extracted from the *Zeitung des Vereins* and published in the *Bulletin du Congrès des chemins de fer* [1].

In this the various systems already referred to are described, the lines on which they are in operation being indicated, and the fact established that transhipment at a level is the system most universally adopted.

It will be seen by the preceding statements that the question now before us is not very new. Nevertheless, it is interesting to take the matter up again, with a view to discovering whether the conclusions arrived at by the Congress in 1889 hold good today. To this end we have drawn up the list of questions reproduced in the form of an annex at the end of the present report. We analyse, grouping them according to the various countries, the replies which have reached us :

I. — GERMANY.

The following administrations have replied to our list of questions :

1° Prussian State Railway (Directorates of Breslau, Elberfeld, Erfurt, Frankfort on the Main, Halle on the Saale, Stettin);
2° Alsace-Lorraine State Railway;
3° Bavarian State Railway;
4° Saxon State Railway;
5° Wurtemberg State Railway;
6° Munich Local Railway Company.

The various replies may be summed up as follows :

Prussian State Railway.

There exist in the districts enumerated above, 53 intallations for the exchange of goods between the standard-gauge system and narrow-gauge lines of varying measurements (0·60, 0·70, 0·75, 0·90 and 1 metre [1 ft. 11 $^5/_8$ in., 2 ft. 3 $^9/_{16}$ in., 2 ft. 5 $^1/_2$ in., 2 ft. 11 $^7/_{16}$ in., 3 ft. 3 $^3/_8$ in.]).

As regard two of these (Hohemlimburg and Plettemberg, in Westphalia), the

(1) See N° 5, May 1894, p. 359.

exchange is effected by means of carrying-trucks *exclusively*; the fifty-one others all employ the level method (eight among them concurrently with the employment of carrying-trucks). Under the heading of " transhipment at a level " we include not only arrangements by which the tracks are at the same level, but those by which the floors of the trucks are brought to the same level by a slight elevation of the narrow-gauge line-relatively to the standard-gauge line.

Seventeen of these exchange stations have, in addition, a raised-track arrangement, and in eight of such cases transhipment is further facilitated by the fact that the wagons of the narrow-gauge line have truck-bodies which swing over, or have a hopper bottom or one with a shelving ridge.

Figures 1 and 2 show : 1° cross-section of the raised track at Abendstern, where the narrow-gauge track transfers annually to the ordinary line by means of tip-wagons about 50,000 tons of mineral ore and limestone; 2° the cross-section of the arrangement at Kerkerbach, whereby the narrow-gauge track is laid upon a small bridge at right angles to the ordinary line. The floors of the trucks of the narrow-gauge line are made with a shelving ridge at the bottom.

These raised-track arrangements are met with most frequently at stations where there is an important exchange of goods little liable to damage (such as sand, mineral ore, gravel, beet, potatoes, etc.). The objection raised, however, against such arrangements is that they have the drawback of being fatal to the preservation of the floors of the trucks on the lower line, when the transhipped goods are too heavy or sharp-edged (ashlar, paving-stone, rock ore, etc.).

Further, it is found that the cost of maintenance of tip-wagons and those with a hopper-bottom is of an onerous character.

The cost of transhipment, which is from 2·50 to 3·25 francs (2*s.* to 2*s.* 7 $^1/_2$ *d.*) per 10-ton wagon where the level system is employed (25 to 40 per cent more for goods requiring a certain amount of arrangement, such as bricks, briquettes, etc.), descends to 1·50 or 2 francs (1*s.* 2 $^1/_2$ *d.* to 1*s.* 7 $^1/_2$ *d.*) under the raised-track system, and to 1 franc (10*d.*), or even less, if the narrow-gauge line trucks are of the tip type or have a hopper bottom or one with a shelving ridge.

Among the fifty-one exchange stations mentioned above, eight are served concurrently by the level method and by that of carrying-trucks (Langbein system). We give (figs. 3 to 7) plans of the carrying-trucks and of a sunk stowage track. (For a more detailed description of these contrivances we must, in order to avoid making the present report too long, refer the reader to the May 1894 number of the *Bulletin du Congrès des chemins de fer*, and to the *Annales des ponts et chaussées de France*, for the years 1894 and 1899.)

The Prussian State Railway considers that apparatus of this kind renders valuable service in preventing the necessity for the transhipment of specially fragile goods such as tiles, pottery, glass-ware, etc., but that their employment is not always possible (notably in the case of wagons with three axles); furthermore, they cannot, without some inconvenience, be intercalated in passenger trains; their use, therefore,

is chiefly to be recommended when the question is one of serving certain special manufactories linked up with the narrow-gauge line at points not very far distant from the junction station with the standard-gauge line.

The Prussian State Railway mentions, finally, that in four cases the narrow-gauge line has been equipped (over a short length of track) with a supplementary rail enabling certain special establishments to be served without transhipment. In particular, at Kerkerbach Station, there abuts a track with three rails, 3,700 metres (2·17 miles) in length, serving lime-kilns which dispatch and receive about 50,000 tons yearly. The extra expense due to this third rail may be estimated at 37,500 francs per kilometre (£2,414 per mile). Objection is raised to this arrangement, on the one hand because of the complication in the switches, and on the other because it involves the necessity for inserting a special truck (with triple buffing-gear) between the locomotive of the narrow-gauge line and the standard-gauge trucks.

Alsace-Lorraine State Railway.

Besides the exchange station at Luxemburg, to which reference is made farther on (see the heading " Grand-Duchy of Luxemburg "), the administration of the Alsace-Lorraine State Railway possesses three other installations for exchange with narrow-gauge lines.

These installations only admit of the level arrangement.

At Colmar, the iron road between the station and the port is fitted with three rails, access to the quays being thus permitted to vehicles of both gauges.

Bavarian State Railway.

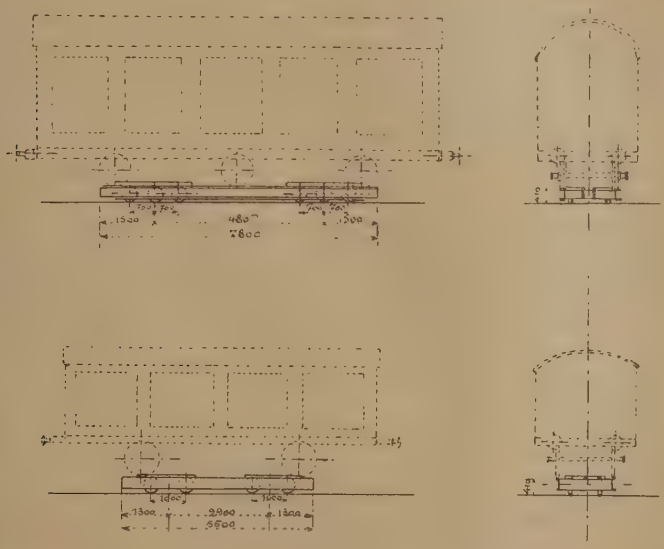
The exchange of goods at the Eischstätt-Kinding station is effected by crane so far as round timber is concerned, and by carrying-trucks, of the Langbein type, in the case of other goods; in the case of the latter, transhipment from truck to truck is exceptional (as for example, when the standard-gauge wagons have three axles, and consequently cannot be loaded upon trucks); it is effected, in such an event, by means of a transhipment platform extending from the goods-warehouse of the station.

For the round timber which constitutes the principal article of exchange (18,000 tons per annum), use is made of a travelling crane above a line with four rails; the narrow-gauge truck is first brought, loaded with wood, under the crane; the load is raised, and then the truck is withdrawn and replaced by a standard-gauge one, upon which the load is lowered.

With regard to the carrying-trucks, these have been in use since 1887 without ever having given rise to inconvenience; their employment, however, renders it necessary that the speed of the trains in which they are intercalated shall not exceed 15 kilometres (9.3 miles) per hour.

Saxon State Railway.

Twenty-five stations on this system exchange goods with narrow-gauge lines. They all include transhipment at a level; in every case, also, use is made either of carrying-trucks, or carrying-wagons. These carrying-wagons are composed of a floor supported on two bogies (of two or three axles each) and furnished with two rails 1·435 metres (4 ft. 8 $^1/_2$ in.) apart (figs. 8 to 11). The standard-gauge trucks are brought up along a loading ramp, furnished with a standard-gauge line on a level with and in extension of that of the carrying-wagon.



Figs. 8 to 11. — Carrying-trucks of the Saxon State Railway.

The Saxon State Railway prefers the carrying-wagons to the carrying-trucks, on the ground that they appear to present more security and to be more easily managed. It is necessary to state, however, that the dead weight of these carrying-wagons exceeds by at least 26 to 30 per cent that of the carrying-trucks. Unlike the trucks, they can receive three-axled standard-gauge wagons.

As to the cost of transhipment at a level, this naturally varies according to the class of goods dealt with. It gets as low as, roughly speaking, 2 francs (1*s.* 7 $^1/_2$*d.*) per 10-ton wagon for goods in sacks, and rises to about 3·50 francs (2*s.* 10*d.*) in the case of less easily-handled goods.

Wurtemberg State Railway.

This system includes six stations of exchange with narrow-gauge lines (gauges 0·75 and 1 metre [2 ft. 5 1/2 in. and 3 ft. 3 3/8 in.]). In these six stations the method of transhipment is that of at the same level, and is supplemented by travelling cranes (principally for the purpose of dealing with timber). In the case of all fragile goods use is made, at the six stations referred to, of carrying-trucks.

Munich Local Railway Company.

This company has sent us a note giving very interesting details regarding its operation of the Urban Tramways of Forst (Brandenburg). These tramways have a 1-metre (3 ft. 3 3/8 in.) gauge; seventy-seven manufactories are linked up with them. The goods traffic (in the two directions) reaches a total of about 23,000 trucks of 10 tons each per annum; the greater part of this traffic (*i. e.* about 19,000 trucks) consists of coal brought by the standard-gauge line to Forst Station and there taken up by the tramway for distribution among the associated manufactories.

All this traffic between Forst-Station and Forst-Town is carried on exclusively by means of carrying-trucks (there are 98 in use). The three sunk stowage tracks installed at Forst Station are regulated so that each can receive at once ten pairs of trucks; the main line can therefore bring or retake at one time 30 trucks of standard-gauge.

In ordinary working 60 to 80 large loaded trucks pass daily from one line to the other, and as many empty trucks.

The coupling of the carrying-trucks with each other and with the locomotive of the narrow-gauge line is effected by means of bars of about 3 metres (10 feet) in length; each vehicle thus preserves the play necessary for its passage round curves the radius of which may not exceed 15 metres (3/4 chain).

This use of carrying-trucks for the purpose of establishing a sort of urban iron-road drayage is evidently most advantageous to the local industries; in addition, it greatly facilitates the service of the main-line station, and frees the municipal authority from the comsiderable expense which would be necessitated for repairs to its highways if the 230,000 tons carried annually by the Langbein trucks had to be conveyed by cart.

II. — ARGENTINE REPUBLIC.

The Buenos Ayres-Rosario-Argentine Central Railway (gauge 1·676 metre [5 ft. 6 in.]) possesses seven stations of exchange with various lines of a narrower gauge (0·75, 1 and 1·435 metre [2 ft. 5 1/2 in., 3 ft. 3 3/8 in., 4 ft. 8 1/2 in.]). In the case

of all these stations there is no transhipment arrangement other than that at a level.

III. — AUSTRIA-HUNGARY.

Austrian State Railway.

On the Austrian State Railway there are eighteen stations of exchange with narrow-gauge lines. All these stations are established in conformity with the level system; one of them possesses in addition, a raised-track arrangement. In the case of four others, certain exchanges are effected by means of carrying-trucks.

Hungarian State Railway.

The Hungarian State Railway possesses fifteen stations where goods are exchanged with narrow-gauge lines. These fifteen installations all possess an arrangement for transhipment at a level. Four among them have, in addition, a raised-track, and two others a sunk-track, system. One installation alone makes use of carrying-trucks.

Austrian North-Western Railway (and German South-North Junction).

Upon this railway there are two exchange installations. In one (Reichenau) where the traffic, to a greatly-preponderating extent, is from the standard-gauge to the narrow-gauge line (37,000 tons in the one direction and less than 1,000 tons in the other), there is, in addition to the level system, a sunk-track arrangement (see cross-section, fig. 12). In the other station (Friedland), which serves, at the point

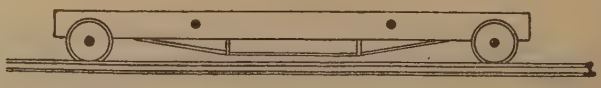

Fig. 18. — Elevation of a truck.

of departure of the narrow-gauge line, a rather considerable traffic in pottery and manufactured articles, use is made of carrying-trucks concurrently with the level system.

IV. — BELGIUM.

The narrow-gauge system of Belgium (3,350 kilometres [2,082 miles] in operation on 30 June 1909) possesses a hundred and forty-five points of exchange with lines of the standard-gauge. All these exchange stations have the level arrangement; in the case of one only of them, the Langbein carrying-trucks are also used (principally for the conveyance of sulphuric acid in tank-trucks) and, in one other carrying-wagons (chiefly for the transport of certain exceptionally friable kinds of coal). The goods utilizing these special contrivances reach, however, only a very limited tonnage.

No example of either sunk or raised tracks can be met in the exchange stations mentioned above; but the plan of fitting with four rails a few sections of narrow-gauge line has met with a certain amount of favour. Six separate sections, measuring altogether about 40 kilometres (25 miles), have been equipped in this way (three among them serving quarries, two others ceramic-produce factories, and the last a coal-mine).

The arrangement with four rails is preferred to that with three, as it avoids all eccentric action in the haulage of standard-gauge trucks by narrow-gauge locomotives. This haulage is effected, either by means of an intermediate truck fitted with a double coupling, or by equipping the locomotive itself with this double coupling.

In the opinion of the Belgian National Light Railway Company, the equipment of the line with four rails constitutes (principally from the point of view of facility in working) an excellent solution of the problem of serving without transhipment manufactories with a large traffic; but this solution is costly (an increase of at least 25,000 to 30,000 francs [£1,609 to £1,930] per kilometre for the regular line and of 3,500 francs [£140] for each switch); it is not, therefore, to be recommended unless the sections to be so equipped are short.

We give (figs. 19 to 23) a few sketches showing the arrangements adopted for the switches of these lines with four rails; these switches clearly constitute the most delicate appliance in the installation.

As regards transhipment at a level, this is effected in Belgium under conditions similar to those of neighbouring countries; it is generally carried out by the management of the narrow-gauge line at the regulation price of 25 centimes (2·44*d.*) per ton (40 or 50 centimes [3·90*d.* or 4·88*d.* per English ton] for timber. At the same time, consignors are allowed the latitude of adopting their own methods of procedure, and they not infrequently avail themselves of such latitude where there is a question of regular and important traffic, as by so doing it is possible to realize a saving of from 20 to 30 per cent in the regulation price.

Figs. 19 to 23. — Special switches for tracks with four rails. Gauges of 1 metre and 1.435 metres (3 ft. 3 $^{3}/_{8}$ in. and 4 ft. 8 $^{1}/_{2}$ in.).

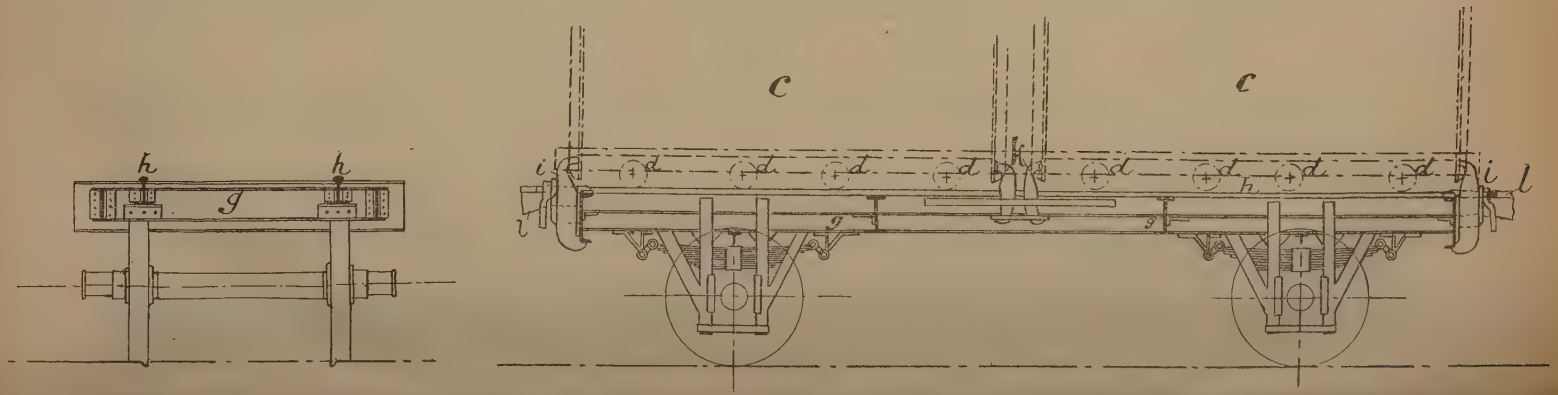

Figs. 26 and 27. — Flat wagon of the standard gauge line carrying two truck-bodies.

V. — DENMARK.

Danish State Railway.

Three narrow-gauge lines are linked up with the Danish State Railway. The transhipment arrangement adopted at the junction-stations is that on a level. An interesting point arises, however, in connexion with the narrow-gauge track from Kolding to Egtved. This line has had constructed special flat trucks of the two gauges (twenty-four for the narrow-gauge line and six for the standard); the floors of these flat trucks are provided with two lines of rail designed to receive movable truck-bodies mounted upon wheels 0·16 metre (6 $^{5}/_{16}$ miles) in diameter (see figs. 24 to 27). In the exchange station there has been constructed a standard-gauge line prolonged from one of the narrow-gauge lines (the centre lines of the two tracks are thus in a straight line), the standard-gauge track being 0·40 metre (1 ft. 3 $^{3}/_{4}$ in.) lower than the narrow-gauge line. As the rails upon the floors of the flat trucks of the ordinary-gauge line are 1·23 metre 4 ft. $^{7}/_{16}$ in.. above the rails of the latter, whilst the corresponding figure is only 0·83 metre (2 ft. 8 $^{11}/_{16}$ in.) for the flat trucks of the narrow-gauge line, it is obvious that, if one brings upon the latter a train of flat trucks furnished with their movable truck-bodies, and if ends of loose rails are placed between the successive trucks in order to secure the continuity of the path over the raised surfaces, it is possible, by a simple working of the chain, to make the series of movable truck-bodies (attached together) pass from the flat trucks of the narrow-gauge line on to the train of flat trucks of the standard-gauge line.

Each truck-body is capable of holding 5 tons; the line possesses fifty-four open ones and six closed. Their chief service is to carry the traffic between the narrow-gauge line (which serves important sugar-works) and the port of Kolding, which possesses only standard-gauge tracks. They are of further assistance in conveying to the main line-stations — as far, even, as Berlin itself — delicate commodities that will not stand transhipment (cauliflowers, for example).

VI. — EGYPT.

The Egyptian State Railway has twelve stations of exchange with lines of narrow-gauge not worked by itself, and a thirteenth with a narrow-gauge line forming part of its own system. The level arrangement is adopted in the case of all these points of exchange. It gives satisfaction to the administrations concerned and to the public.

VII. — SPAIN.

The only particulars which have reached us have been furnished by the Spanish Northern Railway Company, which operates twelve stations of exchange with lines

of a gauge different from its own. In the case of all these stations the level system is adopted. Nevertheless, at the station of La Robla, where the narrow-gauge line from La Robla to Valmaseda joins, which brings to the main line an important coal traffic (40,000 tons annually), the transhipment of these goods is effected by the raised-track system.

The company is of opinion that, despite all the care exercised in the work of transhipment, some damage is inevitable, principally in the case of goods of a delicate nature such as fruit; and in certain cases consignors are induced to make use of a longer route in order to avoid the necessity for transhipment.

VIII. — UNITED STATES OF AMERICA.

Lines of a gauge other than the standard are very rare in the United States; therefore the majority of the railway companies which have replied to us state that they do not possess transhipment stations.

The Pennsylvania Railroad has two of them (traffic of but little importance) where the exchange of the goods is effected by the level method.

The Boston & Maine Railroad possesses at the station of Hoosac Tunnel an exchange station for the service of the narrow-gauge line which joins it there (Hoosac Tunnel & Wilmington Railroad). Transhipment is there, also, effected by the level system, the two lines of exchange being separated by a raised stage (transhipment stage) of timber-work, about 3 metres (10 feet) in breadth, set on a level with the floors of the trucks. The principal object of this transhipment stage is to permit loading and storing of goods, even when the trucks (of the other gauge) which ought to receive them have not arrived. The exchange traffic amounts to about 8,000 tons per month; the cost of transhipment is about 50 centimes (4·88*d.* per English ton) per ton.

The Baltimore & Ohio Railroad has sent us an interesting note on the subject of the exchange station at Fixburg (Pennsylvania). This station possesses an arrangement for transhipment at a level similar to those of the European companies. About 10,000 tons are handled there monthly, at the cost of about 50 to 60 centimes (4·88*d.* to 5·85*d.* per English ton) per ton (wages of transhipment employees: 90 centimes [9*d.*] per hour).

If, in the case of certain goods, it is desirable to avoid transhipment from truck to truck, use is made of the " Ramsey " sunk track (see figs. 13 to 18) which enables the bodies of standard-gauge cars to be placed on narrow-gauge trucks, and vice-versa (it is well known that in the United Stetes the majority of the cars are on bogies). To this end, the sunk track (fitted with four rails) has on each side a track with a gauge of about 0·50 metre (1 ft. 7 $^{11}/_{16}$ in.), on which small carrier-wagons can travel. By means of transverse rails resting upon these small wagons and of sleeper blocks, the body of the trucks can be supported upon the said carrier-wagons; by a movement of the whole system above the sunk track, a separation is

effected between the truck-body and the bogies of standard-gauge; these bogies are shunted by means of the turn-table indicated in the sketch, and those of the narrow-gauge are brought up with a view to the reverse operation.

The cost of a Ramsey sunk track is about 10,000 francs (£400), and the substitution of the trucks as described above involves in respect of manual labour an outlay of about 2·75 francs (2*s*. 2 1/2 *d*.) per truck, that is to say 20 to 25 centimes per ton (1·95*d*. to 2·44*d*. per English ton); the trucks utilizing the Ramsey sunk track are chiefly of 12 tons or less.

IX. — FRANCE.

French Eastern Railway.

Up to the present time there does not exist in the stations at which lines of narrow-gauge terminate any arrangement for transhipment other than at the same level. The traffic exchanged is of small importance; the net cost of transhipment is at least 30 centimes per ton (2·93*d*. per English ton).

Carrying-trucks ran for some time on a narrow-gauge line in the Ardennes; but the company working this line no longer uses them.

French State Railway.

Exchanges with narrow-gauge lines are effected by transhipment at a level. The work is usually entrusted to piece-workers; the price paid to them for it varies according to the stations and amounts on an average to 21 centimes per ton (2·05*d*. per English ton).

Nothing has occurred to suggest that the desire to avoid transhipment has taken away from narrow-gauge lines any class of traffic.

As the station of Melle (Deux-Sèvres), carrying-trucks of the Langbein type are used in order to secure the traffic of the distillery of Mardre upon the line (of 1 metre [3 ft. 3 3/8 in.] gauge) from Sainte-Maixent to Melle. This manufactory, situated 3,500 metres (2·2 miles) from the junction-station, receives and dispatches on an average 35 trucks of alcohol daily during the active period of its traffic (October to February). The carriage is effected by special trains, each train comprising at most two loaded trucks of 10 tons or three empty trucks. The cost of the carriage is 70 centimes per ton (6·83*d*. per English ton), all expenses of management included.

French Midi Railway.

The arrangement generally adopted on this system is, as in the two preceding cases, transhipment on a level. Nevertheless, at Cerbère (international station of exchange with the Spanish system), there exists a Spanish line raised 1·03 metres

(3 ft. 4 $^{9}/_{16}$ in.) as compared with the French line; it is by means of these two tracks that the transhipment of mineral ore brought from Spain is effected.

A similar arrangement is contemplated for the exchange station of Villefranche-Vernet-les-Bains, with a view to facilitating the transhipment of mineral ore brought by the new narrow-gauge line from Villefranche to Bourg-Madame.

The cost of transhipment at a level varies from 20 to 50 centimes per ton (1 95 to 4·88*d.* per English ton), according to locality and nature of the goods. As regards transhipment by the raised track at Cerbère, this is carried out under the supervision of the forwarding agents, and the Midi company does not indicate its cost.

French Northern Railway.

The transhipment arrangements invariably include the level system, and frequently sunk and raised tracks. We reproduce by way of specimen a plan of the station of exchange at Doullens (fig. 28), where are transhipped annually about 10,000 tons of goods brought by the main line, and 14,000 tons brought by the narrow-gauge line.

This plan shows that the sunk and raised track methods can be utilized without meriting to any serious extent the charge of obstruction levelled at them at the 1889 Session. We give also (figs. 29 to 32) standard sections of the various transhipment arrangements of the Northern Railway.

The company thus expresses itself in its comparison of these arrangements :

" As regards the greater part of goods of large tonnage, transhipment by means of a sunk or raised track offers tangible advantages over the level system. It is more rapid, more economical, and also less laborious for the workmen charged with the transhipment. These advantages are particularly noticeable in the case of goods in bulk, such as coal, mineral ore, sand, beet, etc., which are transhipped by means of either shovel or pitchfork, and a considerable portion of which falls of itself, when the side doors of the truck are opened, along the tranship shoots into the truck which is being loaded.

" On the other hand, the system of transhipment by sunk or raised tracks has some drawbacks, as for instance in the case of heavy and bulky goods, and again in that of goods likely to suffer deterioration through clashing together.

" In the first of these categories come goods in tightly-compressed bales, the weight of which sometimes exceeds 200 kilograms (440 lb.). In the transhipment of such goods by sunk or raised tracks, special precautions are taken, these consisting chiefly in the use of cords and hooks by means of which the first bales are held in check; after which the remainder can be allowed to fall without fear of damage, the shock they sustain being deadened by those already below.

" The second category comprises the major portion of goods conveyed in sacks.

" It is usually preferable to tranship at a level these two descriptions of goods.

" Finally, transhipment at a level imposes itself in the case of nearly all manufactured goods of every description, whether carried in bulk or in any kind of packing.

" When it is a question of transhipmenl at a level of bales, sacks or cases, the two

Raised track of Economic Railway.

Level track of Economic Railway.

Explanation of French terms : Chemin d'accès à la station = Roadway to station. — Cour des voyageurs = Passenger Office. — Estacade = Raised track. — Cour de transbordement = Transhipment yard. — Accès aux marchandises = Access for goods. — Sentier = Path. — Rue = Road. — Chemin rural = Country road. — Long^{r} utile = Available length.

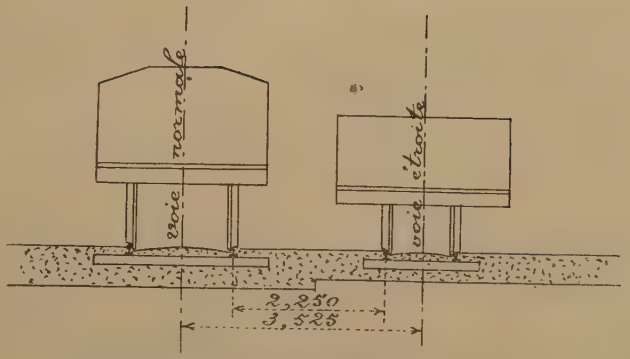

Fig. 29. — Transhipment at the same level.

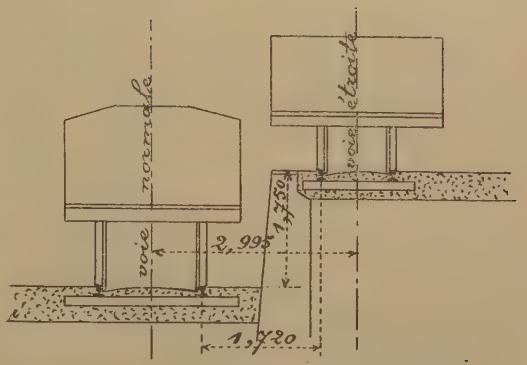

Fig. 30. — Transhipment by raised track.

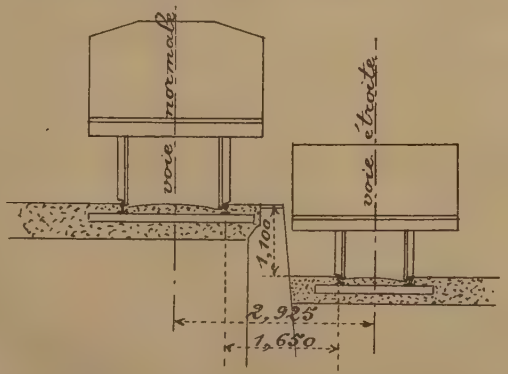

Fig. 31. — Transhipment by sunk track.

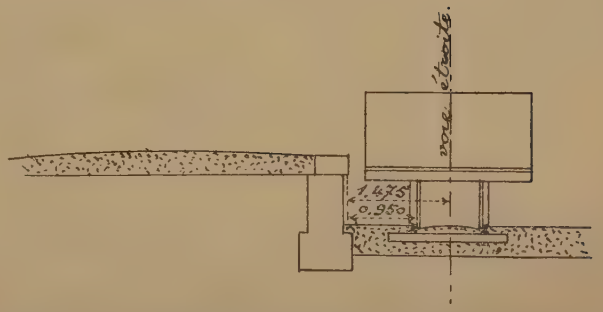

Fig. 32. — Transhipment upon a platform.

Explanation of French terms : Voie normale = Standard-gauge line. — Voie étroite = Narrow-gauge line.

trucks are united by means of a transhipment bridge, upon which one man suffices to pass the goods on by means of a pinch-bar.

" In the case of other goods, the transhipment is effected by hand, all necessary precautions being taken.

" The net cost of transhipment varies according to the district and the nature of the goods. It is estimated that for coal, mineral ore, sand, etc., the cost is from 20 to 30 centimes per ton (1·95*d.* to 2·93*d.* per English ton). For delicate or light goods, the cost does not go below 30 centimes per ton (2·93*d.* per English ton).

" Transhipped goods never suffer damage, practically speaking, through the process of transhipment, and compensation under this head is exceptional and absolutely trifling. In any case, we have never lost traffic over the question of transhipment."

Orleans Railway.

The method of exchange most frequently adopted is transhipment at a level, supplemented very often by a travelling crane serving both tracks, and facilitating the transhipment of indivisible masses of goods of a certain weight. Neither sunk nor raised tracks exist, except in a very limited number of exchange installations; such is the case, however, at Villefranche-d'Allier (line from Sancoins to La Peyrouse, General Light Railway Company), where are annually transhipped about 10,000 tons of fuel brought by the narrow-gauge line. The latter uses side-tip wagons, and the load is shot into the trucks of the standard-gauge line (see figs. 33 and 34). As a specially-interesting case, the Orleans Railway cites that of a consignor of slates who packs his goods into frames holding 5 tons, the frames being manipulated by means of a crane. This procedure has the effect of reducing the duration and risk of damage of the transhipment.

Paris-Lyons-Mediterranean Railway.

This system includes ninety exchange stations serving narrow-gauge lines.

In nearly the whole of these stations, transhipment is effected exclusively at a level: there are extremely few examples of sunk or raised tracks.

Carrying-trucks are in use at the station of Genève-Cornavin (Geneva Company of electric tramways), and give good results there.

The section from Bourbon-Lancy (station) to Bourbon-Lancy (town), having a length of about 2,500 metres (1·5 miles) and forming part of the narrow-gauge line from Bourbon-Lancy to Toulon-sur-Arroux (departmental railway), has been epuipped with four rails for the purpose of avoiding the transhipment of goods between the main line and the town of Bourbon-Lancy. The goods which have in this way escaped transhipment reached, in 1907, a total of about 500 trucks (235 of these being cattle-trucks).

O. = Trucks Paris-Orleans. — Voie Economique sur estacade = Raised track (Economic Railway). — Chemin de roulement = Rolling path. — Wagon Economique basculant = Tip wagon (Economic Railway). — Appareil basculeur = Tipping apparatus.

French Western Railway.

Of the thirty-three stations connected with narrow-gauge lines, that of Chateaubriant alone is furnished with sunk and raised tracks; the whole of the others permit of the level method only. The special installations at Chateaubriant are designed to facilitate the transhipment of limestone brought by the narrow-gauge line on tip-wagons. The operation is very rapid (a few minutes suffice for four men to tranship 9 tons of limestone) and the net cost does not reach 10 centimes per ton (0·98*d.* per English ton).

For the transhipment from the standard-gauge trucks into the narrow-gauge trucks, the sunk-track arrangement, with shovelwork (notably in the case of fuel), is used at a net cost of 15 centimes per ton (1·46*d.* per English ton).

In the various stations where transhipment is effected at a level, the average net cost is 20 to 30 centimes per ton (1·95*d.* to 2·93*d.* per English ton).

For the conveyance of slates brought to the main line by the Britanny narrow-gauge system, metallic frames or cases are used similar to those referred to above in connection with the Orleans railway. These cases can hold 3,000 kilograms (6,600 lb.) of slates each; their weight is 340 kilograms (750 lb.) and their price 275 francs (£11) a piece; their dimensions (2·00 × 1·75 × 0·60 metres [6 ft. 1 $^{3}/_{4}$ in., 5 ft. 8 $^{15}/_{16}$ in., 1 ft. 11 $^{5}/_{8}$ in.]) permit of three of them being placed upon a flat truck of the narrow gauge line (see figs. 35 to 38).

These cases give very satisfactory results; they are used for the conveyance of 7,000 to 8,000 tons of slates per annum.

Somain-Belgian Frontier Railway (Mines of Anzin Company).

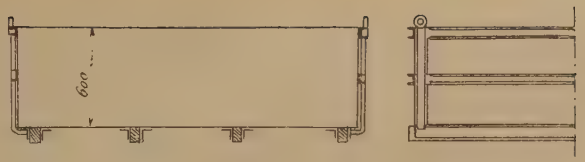
This railway (of standard-gauge) brings to the exchange stations of Anzin and Denain coal which has to go on by the narrow gauge line.

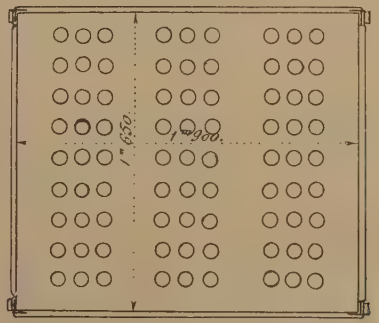
At Anzin, where the quantity exchanged is about 5,000 tons per annum, transhipment from the larger trucks into the smaller is effected at a level in accordance with the usual procedure, and costs 20 centimes per ton (1·95*d.* per English ton).

But at Denain (Renard sunk track), where there is an annual traffic of about 60,000 tons, recourse is had to a special arrangement; the coal is loaded into movable truck-bodies placed upon a truck (of standard-gauge) as shown in figures 39 and 40; each truck-body holds about 1,700 kilograms (3,750 lb.); the total load of a vehicle is six truck-bodies, that is to say 10,000 kilograms (22,000 lb.) net.

A steam-crane raises in succession each truck-body, and swings it into a ten-ton narrow-gauge high-sided truck placed upon a track 8 metres (26 ft. 3 in.) distan from the standard-gauge line.

The net cost per ton transhipped is 8 centimes (0·78*d.* per English ton).





Figs. 35 to 37.

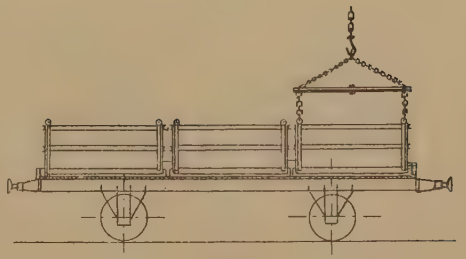


Fig. 38.

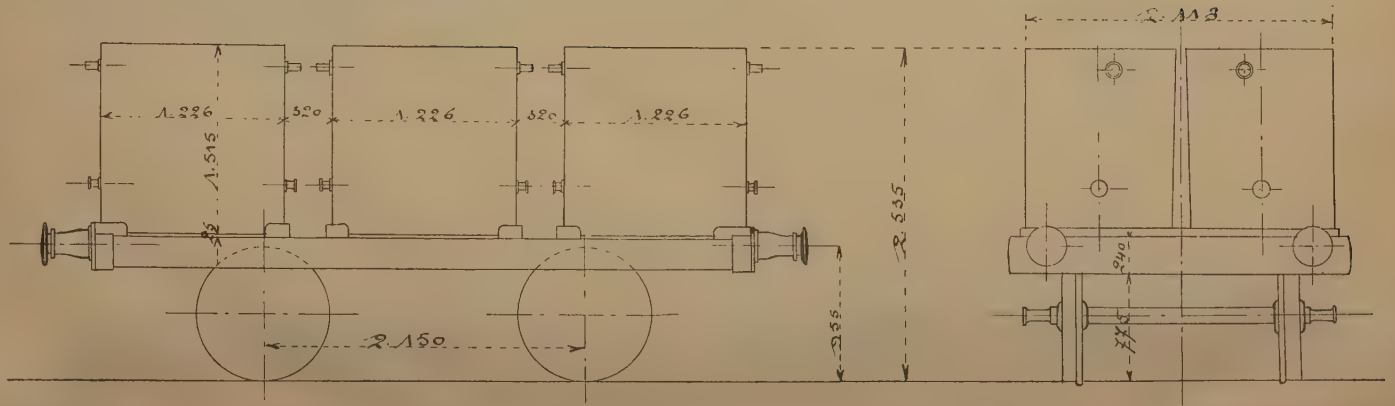

Fig. 39.

Fig. 40.

X. — GREAT BRITAIN AND IRELAND.

A. — UNITED KINGDOM.

In the United Kingdom there are few lines of narrow gauge; transhipment installations are naturally, therefore, not very numerous,

The Great Eastern Railway informs us of the existence upon its system of one single exchange station (Halesworth), at which the traffic is in any case of little importance, and which adopts the level system. It is likewise this method (but with a transhipment platform set on a level with the floors of the trucks) which exists at Ennis and at Tralee (Ireland) at the stations of exchange dependent on the Great Southern & Western Railway.

In Wales, three exchange installations with the Great Western Railway serve the lines from Festiniog (gauge, 0·60 metre [1 ft. 11 5/8 in.]) from Glyn Valley (gauge, 0·70 metre [2 ft. 3 9/16 in.) and from Rheidol (gauge, 0·60 metre [1 ft. 11 5/8 in.]).

In the case of the latter line (annual traffic exchanged 1,000 tons), transhipment is effected solely at a level, but in the two others there is, in addition, a raised-track arrangement, the traffic to the main lines (slates at Festiniog and broken stone for the maintenance of roads at Thirk) being much more important than the traffic in the contrary direction (8,500 tons of slates at Festiniog annually and 17,000 tons of broken stone at Thirk). At Thirk the discharge of the broken stone from the small trucks into the large is effected mechanically, the first being provided with tip sides; thanks to this arrangement, two men can in ten minutes tranship 10 tons of broken stone.

Finally, the North Staffordshire Railway notifies us that the line (recently opened) from Warehouses to Hulme End (gauge, 0·75 metre [2 ft. 5 1/2 in.]) uses with success carrying-trucks (upon two bogies) designed to carry upon the narrow-gauge line without transhipment the main-line stock.

B. — INDIAN EMPIRE AND COLONIES.

The following administrations have been good enough to reply to our questions :

North Western Railway of India;
East Indian Railway;
Southern Mahratta Railway;
Bengal-Nagpur Railway;
Madras & Southern Mahratta Railway;
New South Wales Government Railways;
Western Australia Government Railways;
Natal Government Railways;
South African Central Railway.

On these various systems, the arrangement for transhipment generally adopted

is that at a level, the lines of different gauge being either placed close together, or separated from each other by a transhipment platform on a level with the floors of the trucks. One single different system is notified to us by the Bengal-Nagpur Railway as existing at its station of Gondia, where there is an important exchange of mineral ore; the narrow-gauge trucks have a hopper bottom and are placed upon a line (raised track), underneath which are installed shoots conducting the ore into the broad gauge trucks placed below. By means of these shoots and of the hoppers, the manual labour involved in the transhipment is reduced by more than a half, and amounts to 1·25 franc (1*s.*) per ten-ton truck at most.

XI. — ITALY.

Italian State Railway.

Five transhipment installations with narrow-gauge lines exist upon the Italian State Railway system. All use the level system; one among them, however (Schio Station, Venetia), likewise includes an installation for Langbein carrying-trucks, which are used for the service of a saw-mill connected with the narrow-gauge line.

Bari-Barletta Railway.

This line, with a gauge of 0·75 metre (2 ft. 5 $^1/_2$ in.), carries a good deal of wine in casks (about 15,000 tons annually); these goods are transhipped by means of a paved platform placed between the lines of the two gauges. Other goods are transhipped directly from truck to truck by means of the usual level system.

There are transhipped also from truck to truck, by means of ordinary pumps, liquids in tanks, in particular wine and drinking water (1,000 tons annually).

The cost of transhipment is, per ton, 40 centimes (3·90*d.* per English ton) for the wine in casks, 70 centimes (6·83*d.* per English ton) for the liquids in tanks and 35 centimes (3·41*d.* per English ton) for other goods.

Brescia-Mantua-Ostiglia Railway.

This line is of standard gauge, but on account of certain conditions of construction (radius of certain curves too small and rails of insufficient cross-section) main-line stock cannot circulate there; consequently, it is obliged to tranship, at Mantua, goods to be exchanged with the main system. This transhipment is effected by the level method, without any special feature otherwise, and at the cost of 30 centimes per ton (2·93*d.* per English ton).

XII. — LUXEMBURG.

Prince-Henri Railway.

The Prince-Henry Railway receives at three of its stations (Echternach, Noerdange and Grundhof) lines of narrow-gauge. In the two first stations, the exchange

of goods is effected exclusively by means of the level arrangement. The cost of the operation is 2·25 francs (1*s.* 10*d.*) per ten-ton truck at Noerdange. At Echternach the cost reaches 5 francs (4*s.*) for building timber, 3·60 francs (2*s.* 11*d.*) for tiles, bricks and slates, 4·80 francs (3*s.* 8 $^1/_2$ *d.*) for dressed ashlar; it is as low as 1·50 franc (1*s.* 2 $^1/_2$ *d.*) for manure in sacks.

At Grundhof, the narrow-gauge railway has been built exclusively for the exploitation of the quarries of Dillingen. The whole of the traffic of these quarries (15,000 tons per annum) is dealt with by means of carrying-trucks (Langbein type).

The line possesses six pairs of trucks (at 3,500 francs [£140] the pair) and two sunk stowage tracks, the total expense being about 24,000 francs (£960).

Putting the annual outlay for repairs at 500 francs (£20), and the amortization of the capital at 15 per cent, one finds that the use of carrying-trucks burdens the quarry traffic to the extent of 27 centimes per ton (2·63*d.* per Engl. ton), a figure relatively high, but one which would diminish if the line gave its maximum yield.

Alsace-Lorraine State Railway.

The Alsace-Lorraine State Railway receives at Luxemburg station the narrow gauge line coming from Echternach. Transhipment is carried out at a level, at the cost of about 2·50 to 3 francs (2*s.* to 2*s.* 5*d.*) per 10-ton truck.

XIII. — NORWAY.

Norwegian State Railway.

The particulars furnished to us by the Norwegian State Railway relate to three exchange installations (Christiania, Hamar and Trondheim), where the arrangement adopted has been that at a level.

At Christiania use is also made, for the traffic exchanged between the lines of the Western system (standard-gauge) and those of the Eastern system (gauge 1·067 metres [3 ft. 6 in.]), of carrying-trucks of the two gauges : there are five pairs of carrying-trucks for the narrow-gauge and three pairs for the standard-gauge. The note addressed to us by the Norwegian State Railway points out that, chiefly in consequence of the rather long time necessarily occupied in the stowage of the wagons upon the trucks, the use of the latter is ill adapted to a busy service. We presume, therefore, that the use of carrying-trucks is reserved for goods specially difficult to handle, and that the others are transhipped.

XIV. — THE NETHERLANDS.

From the rather summary particulars transmitted to us, we believe we are correct in assuming that the level method is the only one adopted.

XV. — PORTUGAL.

The Portuguese National Railway Company informs us that it possesses two transhipment stations arranged in accordance with the level system. The principal traffic is in corn (9,000 tons each year from August to November at the station of Foz-Fera). The transhipment of these goods costs 1 franc per ton (9·75*d.* per English ton) (1). In the case of other traffic, the cost of transhipment is about 2·50 francs (2*s.*) per truck.

XVI. — RUMANIA.

The Rumanian State Railway possesses two transhipment stations, one at Jassy and the other at Crasna.

At Jassy, where the question is one of transhipment between a standard-gauge (1·435 metres [4 ft. 8 1/2 in.]) and a broad-gauge track (Russian gauge 1·524 metres [5 feet]), the transhipment lines, set at the same level, are separated by a transhipment platform 6 metres (19 ft. 8 in.) in width, fixed at the height of the floors of the trucks.

At Crasna, where there is a narrow-gauge line connected with the Rumanian State System, the transhipment lines of the two gauges are set at the same level. They are separated by a transhipment platform for the purposes of broken loads, and are installed near each other for the exchanges from truck to truck.

The net cost of transhipment is about 30 to 35 centimes per ton (2·93*d.* to 3·44*d.* per English ton).

XVII. — RUSSIA.

The following administrations have replied to our enquiries :

1° Russian Northern Railway;
2° Nicholas Railway;
3° Russian Southern Railway;
4° Transcaucasian Railway;
5° Vistula Railway;
6° Sysrane-Viazma Railway;
7° Riasan-Ural Railway.

On these various systems, the transhipment tracks are always established practically at the same level, and are generally separated from each other by a transhipment platform set at the height of the floors of the trucks.

As a specially-noticeable point, we may mention that at the station of Scharopane (Transcaucasian Railway) there is a raised track for the transhipment of manganese

(1) We presume that the corn in question is in bulk.

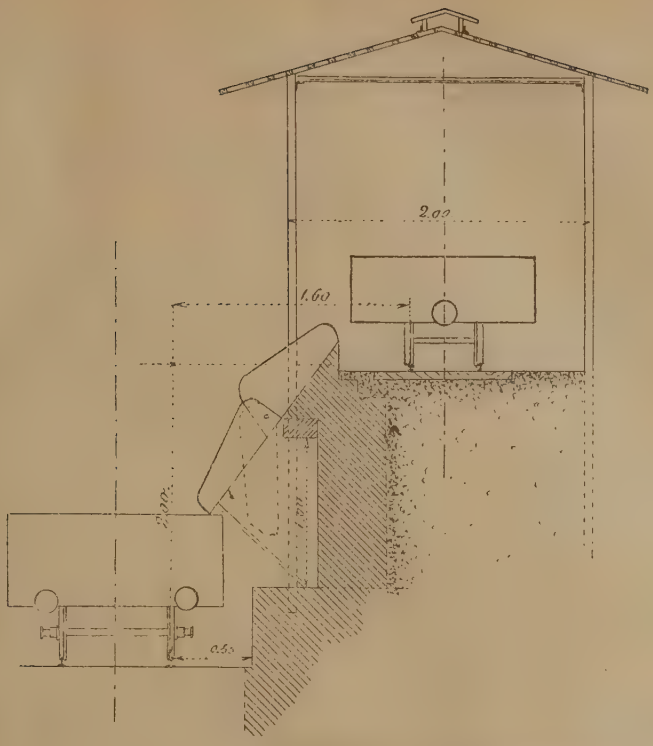

Fig. 41. — Cross-section of raised-track transhipment arrangements.

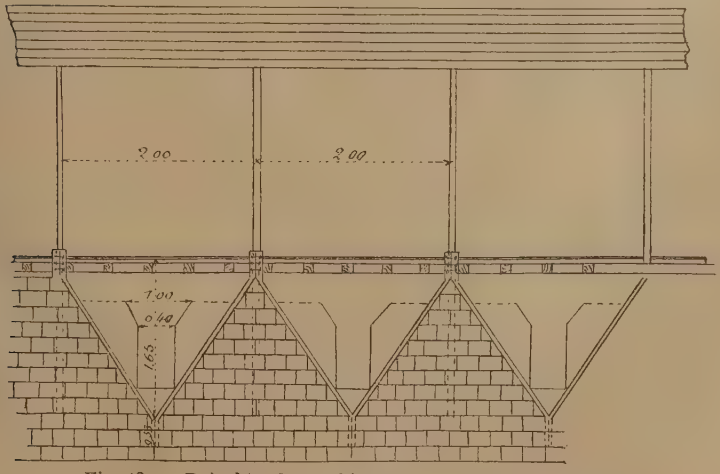

Fig. 42. — Raised-track transhipment arrangement (side view).

*

ore brought by the narrow gauge line. This special traffic amounts to about 600,000 tons per annum; the transhipment costs 1·25 francs (1*s.*) per 10-ton truck. The figures 41 and 42 show this arrangement.

XVIII. — SWITZERLAND.

Swiss Federal Railway.

The Swiss Federal system exchanges goods with narrow-gauge lines at thirty-seven of its stations. These thirty-seven installations all include the level method. In the case of three of them, carrying-trucks of the Langbein type are also used. In no instance has a sunk or raised track been constructed. The transhipment on a level costs on an average 45 or 50 centimes per ton (4·39*d.* to 4·88*d.* per English ton).

The Federal Railway estimates that carrying-trucks may, in particular cases, be used to advantage, as they render it possible to avoid the damage which transhipment may cause to certain classes of goods. But they present certain inconveniences : notably the impossibility of intercalating wagons loaded upon trucks in passenger trains; and thereby involving an extra staff expenditure. Moreover, the dead weight to be carried is greater, a circumstance specially notiaceable in the case of steep gradients.

St. Gothard Railway.

This railway possesses two stations of exchange (Castione and Locarno) with narrow-gauge lines. Transhipment is effected at a level, without special arrangements.

Viége-Zermatt Railway (narrow gauge line).

The exchange station at Viége is included in the thirty-seven indicated above (Federal Railway). Transhipment takes place at a level. About 10,000 tons of goods are exchanged each year during the six months of working.

Rhetian Railway (narrow-gauge line).

This line possesses two stations of exchange (Coire and Landquart) with the Federal system : these two stations are likewise comprised in the thirty-seven referred to above. The level method alone is in operation, and gives complete satisfaction to the lines in connexion and to the public served. The net average cost of transhipment is 43 centimes per ton (4.19*d.* per English ton). No class of traffic is lost to the narrow-gauge line on account of the damage which might be caused by transhipment. The annual traffic exchanged is comparatively large (about 45,000 tons at Landquart).

CONCLUSIONS.

Reviewing as a whole the particulars analysed above, we think ourselves justified in concluding that, in the main, the opinion expressed by the Congress at the 1889 session has not been seriously invalidated by experience, during the course of the considerable development which, chiefly in Europe, the construction of secondary lines of narrow-gauge has made.

Transhipment at a level continues to be adopted in the great majority of cases. It is only right, however, to set forth the fact that the use of carrying-trucks and wagons has been greatly extended, particularly in Germany, where they are utilized at about one-half of the exchange stations dealt with in the replies which have reached us. It may be said of these contrivances that they are practical, and of valuable service in the case of all fragile goods.

Methods involving the elevation of one of the lines of exchange to the height of the trucks of the other line are applicable in every case where important and regular traffic presents itself in certain special products little liable to damage. Such systems are specially advantageous when, for goods of this kind, use can be made of tip-wagons or those with a hopper bottom, so that the amount of manual labour necessitated by the transhipment may be reduced to a minimum.

The arrangements adopted in Denmark and the United States are decidedly ingenious, but for various reasons do not appear to be resorted to very extensively. The same thing applies to the movable truck-bodies used in the mines of Anzin (France).

As regards the arrangements with three or four rails, these have the great disadvantage of being costly; for this reason there can be no question of their use except where important traffic has to be served in the vicinity of the points of junction with the main line. If, on the other hand, the section to be equipped in this way is lengthy, it is more economical and more rational to renounce purely and simply the complexity of a line of double gauge, and to lay down a branch line of standard gauge, provided that very important and remunerative traffic is certain.

To sum up, experience has shown that transhipment from truck to truck by the level method does not constitute, for exchange traffic between lines of narrow gauge and the main railroad, a too onerous charge in ordinary circumstances.

Nevertheless when, in certain special cases, or for certain goods, it is found indispensable to reduce the said charge, carrying-trucks or wagons, sunk or raised track arrangements, the use of tip-wagons and the partial equipment of the narrow gauge line with a track of three or four rails, constitute solutions which experience has proved to be useful and practicable.

APPENDIX.

Detailed list of questions relating to question XX.

1. Do you operate any stations for the exchange of goods from truck to truck between lines of different gauges?

2. If so, please send us plans (scale : 1 in 1,000 or 1 in 500 if possible) of some of them, with lengthwise and crosswise profiles, mentioning the horizontal and vertical distances between the lines used for exchanging traffic, and the measurements of the bodies of the trucks used.

3. If your transhipment arrangements include any sunk or raised tracks, please say so and mention what are the advantages or disadvantages of these arrangements as compared with when the tracks (or at least the floors of the transhipment trucks) are practically at the same level.

4. In the case of the various stations considered above and for the traffic in each direction, what are the principal kinds of goods transhipped and their approximate annual tonnage (or the maximum monthly tonnage if the traffic is such that it varies in quantity according to the season of the year)?

5. Please supply us with some details as to the procedure followed at your stations in transhipment? Do you use any special tools or appliances? Furnish us furthermore if possible with figures regarding the actual cost of transhipment (number of men occupied per 10 ton wagon, time spent in the operation, wages allowed either per hour, or by piece work, etc.).

6. Does your traffic include any goods liable to damage in transhipment? Does such damage involve compensation, or does it result in your losing certain kinds of traffic?

7. With a view to avoid the transference of goods from truck to truck, do you use any special means such as carrying trucks, movable truck-bodies, tracks with three or four lines of rails?

8. If so, please supply us with detailed information about these methods, adding plans or sketches, and give us your impressions about them on the following points :

a) original cost of installation;

b) cost of operation;

c) advantages or disadvantages ensuing both for the industries concerned and for the railway itself.

9. Can you formulate any more or less general rules indicating in which cases each of the solutions considered in your answers is more especially to be recommended?

SECTIONAL DISCUSSION

Meeting held on 9 July, 1910 (morning).

MR. BEHRENS, PRESIDENT, IN THE CHAIR.

The President. (In French.) — Gentlemen, we now begin the examination of question XX. I call upon the reporter to address the meeting.

Mr. de Burlet, *reporter.* (In French.) — Gentlemen, in order to facilitate the arduous task of those entrusted with the translating and the shorthand reporting, I will endeavour to give as brief and concise a summary of my report as possible.

The question of transhipment has already been discussed at several sessions of the Congress and this problem will no doubt remain on its agenda for a long time to come.

This is not surprising. In the first place, it is of considerable importance to all the managements of secondary lines linked with the main railroads; secondly, it is connected with the following important question, often discussed but not yet definitely settled : *What gauge should secondary lines have? The standard gauge or a narrow gauge, for instance one of 1 metre* (3 ft. 3 $^3/_8$ in.)?

A narrow gauge is distinctly cheaper. In our country, Belgium, the figures are as follows : mean cost of a kilometre of standard-gauge secondary line, 102,250 francs (£6,582 per mile); ditto of a kilometre of metre (3 ft. 3 $^3/_8$ in.) -gauge line, 58,000 francs (£3,734 per mile). On the other hand, a narrow-gauge line has the incontestable disadvantage of making it necessary to tranship the goods at the point where the standard-gauge line and the narrow-gauge line meet.

Is this disadvantage sufficiently serious to lead to the adoption of the standard gauge, in spite of its great cost? That is the problem. It is evidently impossible to give a general and uniform solution of it, but it must be dealt with in each individual case with great care, taking all special circumstances into consideration, such as the importance and the nature of the traffic, the length of the line, etc.

In our country, *we have been led to adopt the narrow gauge in nearly every case.*

Out of our 164 lines having a total length of 4,482 kilometres (2,785 miles), we have the standard gauge only on three lines with a length of 39 kilometres (24·2 miles), and we are convinced that if

we had adopted the standard gauge in most of the cases, we should have met with such financial difficulties in trying to raise the capital necessary, that we should have hardly been able to build one third or even one fourth of the existing system.

What would have been the result? That under the pretext of wishing to do *better* for the districts and populations which are scattered and isolated, one would have done *nothing* and they would have had to wait, for goodness knows how many years, before they were connected up by cheap and rapid ways of communication with the main railroad system.

Now it is well known that the development of the prosperity of a district, from the commercial and industrial point of view, is impossible when that district is isolated and only cart traffic is available.

We only adopted the standard gauge in the following case; when it was a question of lines of limited length, which had to deal with a busy traffic of heavy goods.

It is readily intelligible that in such cases the cost of transhipment, even if small, would be too heavy a burden on the goods carried, by increasing the total cost per kilometre unduly.

Hence, we have preferred the narrow gauge in our country, and the same has been the case in many others.

Let us, moreover, note that if as a result of the construction of the narrow-gauge railway, new industries have arisen, or if the existing industries have become developed, and with them the traffic, to such an extent as to justify the standard-gauge on part of the line, nothing prevents the equipment (but at that time only, and then one is safe and certain to remunerate the capital required) of part of the line with three or four lines of rail, so as to save the trouble and expense of transhipment of the heavy goods.

That has been done in Belgium in various cases. As yet there have not been many of them, but this proceeding is entirely rational and justifiable.

My report contains particulars of this interesting solution.

Nevertheless transhipment has disadvantages, and although I am in favour of the narrow gauge, I am careful not to deny this. These disadvantages have to be remembered by all who have to do with light railways and it is not surprising that everywhere attempts are made to reduce them to a minimum.

This explains, I repeat, why this question remains on the agenda of our sessions.

It is however important not to exaggerate these disadvantages, and thereby the disadvantages of a narrow gauge.

To begin with, there is this important fact: these disadvantages are nil as far as passenger traffic is concerned, and this is already a great deal, as passenger traffic yields the greater part of the total gross receipts of the light railways.

In Belgium, in the financial year 1909, the proportion was: passengers, 62 per cent; goods, 38 per cent.

And as regards the goods, what is the cost of the transhipment? From 15 to 25 centimes per ton (from 1·46*d.* to 2·44*d.* per English ton) when the simplest and cheapest methods are used.

That is very little and I continue to believe that in the case of ordinary goods, not liable to loss or damage, special de-

vices, generally of an expensive and complicated character, are not justifiable.

That has been the opinion of our Congress at its different sessions, and has also been the opinion of the tramway and light railway congress.

Subject to these necessary reservations, I think that in order to take the problem as a whole, from the general point of view, I must now consider more especially the subject we have to discuss, which is worded as follows :

Examination of the different systems adopted for the exchange of goods between lines of different gauges (transhipment at the same level, sunk or raised tracks, trucks for taking cars of another gauge, tracks with three or four lines of rails, etc.).

The question which we have to discuss today thus includes more especially a comparative examination of the different means adopted for transferring goods from a standard-gauge line to a narrow-gauge line, or *vice versa*.

The subject naturally has a descriptive side for which I beg to refer my audience to the different drawings given in my report.

I will accordingly limit myself to giving the main features and the chief characteristics of the different systems which have been applied. There are six of them.

I. — My report contains a summary of the information sent to me from all the countries where railway systems with different gauges are coexistent; it may be concluded from this information that *transhipment by hand on lines at the same level* is by far the most usual method. This is the first system. This method of transhipment is that which makes fewest installations necessary. As I have already stated, it does not cost more than 15 to 25 centimes per ton (1·46*d*. to 2·44*d*. per English ton) on the average. This cost can even be reduced very appreciably in the case of a regular traffic of non-fragile goods, such as the raw materials required for industrial purposes generally are.

II. — When the interchange traffic on a narrow-gauge line becomes specialized in such a way that it includes a large tonnage of goods *of one and the same kind*, it may happen that in spite of the low unit cost of transhipment, the total cost of the latter for the whole of the annual tonnage represents a comparatively large sum. In cases of this kind, it is evident that those concerned investigate whether special appliances will enable them to effect a saving in this expenditure. It is for this reason that in order to use gravity so as to facilitate the work of transhipment, the narrow-gauge line has been raised relatively to the standard-gauge line if there is an important traffic brought by the former, or sunk if the traffic is brought by the latter. This method is often adopted at the stations of the French Northern Railway; it has, however, sundry disadvantages as regards the good preservation of the rolling stock and of sundry kinds of goods (coal, for instance). It is sometimes supplemented by the use of hopper wagons or of wagons with movable sides. It is also possible to have a movable floor, so as to have practically complete self-discharging; but then it is necessary to have the narrow-gauge line vertically above the standard-gauge line. Thus we have the arrangement at Kerkerbach station, in Germany.

III. — With the same object of reducing

the labour in the case of goods not easy to handle, gantry cranes are used extending across both the standard-gauge and the narrow-gauge lines. These appliances are used chiefly for the transhipment of logs of timber, parts of machines, etc. In those cases, the tracks can be left at the same level and the handling of the goods is facilitated by the mechanical appliances. My report describes several installations of this kind existing in Bavaria and in Wurtemberg. In France, the use of cranes is combined, at certain stations, with the use of truck-bodies for holding coal, or special frames for holding slates; these holders, together with their contents, are easily lifted by the crane from the flat wagons of the standard-gauge line to those of the narrow-gauge line or *vice versâ*.

Movable truck-bodies are also found, as described in my report, on a Danish line; but there they are not operated by means of a crane. They are mounted on wheels and so can be run endways from one flat truck on to another of a different gauge.

IV. — Finally, in the United States, advantage is taken of the ease with which wagon bodies can be detached from the bogies which carry them; by means of a very ingenious system of sunk track, the bogies are replaced by others of a different gauge.

V. — Strictly speaking, there is no transhipment of goods in the latter cases; nor is there any when carrying-trucks are employed, as they are on the large scale in Germany, where carrying-trucks are used for conveying standard-gauge wagons to and from works connected by narrow-gauge lines only. The objection often raised against these trucks is that they materially increase the dead weight which has to be hauled on the narrow-gauge line; but this objection has not prevented this system from being frequently applied on lines where fragile goods have to be exchanged. The most typical instance of the use of carrying-trucks is beyond doubt that of Forst in Brandenburg; there more than 23,000 wagons are annually loaded on carrying-trucks and hauled over seventy-seven different branch lines.

It is questionable whether it would not have been better to adopt the standard gauge, seeing the large quantities involved.

VI. — I still have to mention, in order to complete my summary, the arrangements with three and four rails, utilized in certain rare cases, chiefly in Germany and in Belgium. These arrangements are expensive and their use seems to clash somewhat with the quality of cheapness which narrow-gauge lines are generally intended to possess. They can accordingly only come in question in the case of very important traffic of a special kind, carried for short distances.

To sum up. experience has shown that transhipment from truck to truck by the level method does not constitute, for exchange traffic between lines of narrow-gauge and the main railroad, a too onerous charge in ordinary circumstances.

Nevertheless when, in certain special cases, or for certain goods, it is found indispensable to reduce the said charge, carrying-trucks or wagons, sunk or raised track arrangements, the use of tip-wagons and the partial equipment of the narrow gauge line with a track of three or four

rails, constitute solutions which experience has proved to be useful and practicable. (*Long applause.*)

I venture to send round some photographs which show you the arrangement of a four-rail line and an intercalating wagon equipped with two couplings, as well as photographs of a train consisting of a standard-gauge wagon hauled by a narrow-gauge locomotive.

The President. — I declare the discussion opened. I again remind the members of the section that they are requested not to speak until they have applied to the president and been requested to by him to do so; they are also requested to stand up when they address the meeting. It is indispensable that these rules should be observed, so that the discussion may be an orderly one, and not degenerate into a series of interruptions which would make the discussion incomplete and confused.

Mr. Campiglio, Italian Union of railways of local interest. (In French.) — I desire to address the meeting.

The President. (In French.) — Mr. Campiglio will address the meeting.

Mr. Campiglio. (In French.) — In Italy, the question of carrying-trucks has been investigated. As this question is connected with that of transhipment, I ask your permission to say a few words about it.

The nature and the quantity of the traffic has to be taken into consideration, the mean distance the goods are carried and the conditions affecting the exchange of rolling stock.

In Italy, the conditions relating to the hiring of the rolling stock are generally very onerous, and the situation has been made still more onerous by the administration of the State Railway.

In Germany, in Austria, in France and in other countries, twenty-four hours are generally allowed free of charge, but in Italy, in most cases, only six to eight hours are granted. Accordingly, it is necessary to tranship as quickly as possible, or else expense is incurred. It is advissable to recommend all administrations who make such conditions to be more reasonable and more equitable to the light railways, so that the latter can develop, as is desirable.

The state of affairs has been very fully described by Mr. de Burlet. I accordingly limit myself to the request that a short clause should be added to Mr. de Burlet's conclusions; the clause to run as follows :

" In investigating the question whether it is advisable to adopt the special installations mentioned in the preceding clause, consideration has to be given to the quantity and to the nature of the goods, to the distance they have to be carried and to the conditions relating to the exchange or hire of the rolling stock used for those goods (dues which have to be paid, time of utilization of the wagons, etc.)."

Mr. de Burlet. (In French.) — I propose to examine this amendment when we start discussing the wording of the conclusions which are to be submitted to the general meeting.

Mr. von Ziffer, Lemberg-Czernowitz-Jassy Railway, Austria. (In German.) — This question, which has been described

as " that night mare of the cost of transhipment ", does not seem to have sufficient importance to lead one to refrain from obtaining concessions for building and operating narrow-gauge railways. In the use of carrying-trucks, I see a very annoying increase in the cost of carriage; as, on the other hand, the maximum moving dimensions are the same as on standard-gauge lines, the cost of construction becomes greater; moreover, the dead weight which has to be hauled becomes greater. Finally, while admitting that the use of carrying-trucks is an unavoidable evil when certain fragile goods have to be carried, I would remark that this evil is aggravated by the fact that according to the Austrian regulations now in force, only one single carrying-truck may be used per train, and that truck must be fitted with a brake.

I therefore should like to know whether the same or similar regulations exist in other countries, and also whether the cost of transhipment is included in the rates of your tariffs, or charged separately to consignors.

Remarks made by different delegates seem to imply that such hampering regulations do not exist, and that the cost of transhipment is charged separately in most countries, the consignor or the consignee having the option of having the tranship operations carried out by his own men, if he considers this advisable. In British India, the cost of transhipment in included in the tariffs; in calculating the rate, 3 miles are added to the distance.

Mr. de Burlet. (In French.) — I will at once answer the remarks that have been made, so as to simplify the discussion.

Mr. Campiglio proposes to add a clause to the conclusions which I have had the honour to submit to the section.

I propose to wait until the general discussion is finished, before discussing this amendment. (*Approval.*)

Mr. von Ziffer asks how the charge for transhipment is setled in other countries. In Belgium, it is fixed at 25 centimes per ton (2·44*d.* per English ton); special regulations exist about the subject. The cost of transhipment is always added to the rate, and it is paid by the consignor or the consignee. But all this is known to the parties concerned; it is specified in the rules and conditions of the tariffs.

I add, and this is very important, that the consignor has the right to carry out the transhipment operations himself. Let me assume that the consignor prefers not to pay the charge of 25 centimes per ton (2·44*d.* per English ton); he then has the right to send a gang of men to the transhipment station to carry out the tranship operations; he then does not pay the charge of 25 centimes per ton.

Mr. von Ziffer. (In French.) — That is just the same with us.

Mr. du Beaufret. Bône-Guelma Railway, Algiers. (In French.) — The question of the transhipment is of particular importance to the Bône-Guelma Railway Company. We have a very busy traffic on about 235 kilometres (146 miles) of line. The first 128 kilometres (80 milles) are narrow-gauge line; the next 107 kilometres (66 miles) are standard-gauge line. We carry per year over 300,000 tons of heavy goods, chiefly phosphates. The transhipment, although it takes places at 128 kilometres (80 miles) from the sending station

and at 107 kilometres (66 miles) from the receiving station, is carried out, according to the conditions of the tariff, by the consignor, who succeeds in carrying out these operations at a cost of about 15 centimes per ton (1·46*d.* per English ton) in the case of phosphates. All that we have done is to raise the narrow-gauge track in order to facilitate the transhipment.

We have begun an investigation which is not without interest. The two parts (narrow-gauge and standard-gauge) of the line considered are not subjected to the same traffic rules. On the narrow-gauge line, we carry practically only heavy goods, while on the standard-gauge line we carry goods of all kinds and, more particularly in summer, cereals in large quantities. It sometimes happens, during the cereals season, that there is a shortage of standard-gauge wagons for transhipments from the narrow-gauge to the standard-gauge line. Attempts have been made to solve this difficulty and the following suggestion has been made; would it not be possible to prevent any delaying of the narrow-gauge wagons, although there is a shortage of standard-gauge wagons? It is proposed to erect at the transhipment stations hoppers of large capacity and store the phosphates arriving on the narrow-gauge line. The train on the narrow-gauge line arriving on the raised track is at once emptied into these hoppers and the narrow-gauge wagons are then sent back at once. The hoppers would subsequently discharge their contents into standard-gauge wagons when these are available. In this way, the standing idle of the narrow-gauge wagons would be prevented.

An objection arose not on account of the number of phosphate companies (there were only two and definite hoppers could have been provided for each of them), but above all on account of the fact that the phosphates varied in quality. That was the chief objection, for at different seasons the quantities of phosphates of a given quality vary.

Mr. de Burlet. (In French.) — The system then did not succeed?

Mr. du Beaufret. (In French.) — We have not applied it; it was merely suggested, as I stated.

Mr. de Burlet. (In French.) — Oh, then it is as a question of a suggestion only, so let us not press it. It is better for us to discuss actualities, sanctioned by practice or made the subject of serious experiment, than simple ideas. The latter may be very interesting, but in my opinion we must wait until this system has been applied, before we examine and discuss it.

Mr. Charignon, Ministry of communications, China. (In French.) — Gentlemen, I ask your permission to express myself in French, hoping that at some future session you will allow me to do so in Chinese. (*Laughter.*)

The empire of China, from the point of view of its railways, is still in the period of construction; the total length of the lines in operation does not exceed 5,000 kilometres (3,100 miles) and all are of standard gauge, namely 1·45 metres (4 ft. 9 in.), except one line. The latter is a metre (3 ft. 3 $^{3}/_{8}$ in.)-gauge line, about 250 kilometres (155 miles) in length, and connects the capital of the province Shansi with the main line from Peking to Han-

kow; it conveys the coal from a very rich coal field to the plains of China and carries up to 2,000 tons of it per day.

Accordingly, the question of transhipment at once arose as being of great importance, and rather than adopt the different systems described by Mr. de Burlet in the report he has presented to us, we have tried to eliminate transhipment by using special wagons with axles of adjustable length. In doing this, we have simply applied to the carriage of goods the excellent solution which makes it possible for the train of His Majesty the Tsar of Russia to pass from the Russian lines on to the European lines, where the length of the axles differs by about 9 centimetres (3 $^{9}/_{16}$ inches). The problem was however more difficult with us, as we had to provide for a difference of 0·45 metre (1 ft. 5 $^{11}/_{16}$ in.) between the two gauges.

The concessionary company had several different patterns designed and constructed in China itself. All gave very good results, and were adopted definitely after a total mileage of over 10,000 kilometres (6,200 miles) on the standard gauge. They give every satisfaction, although they run through districts in which the winds, which often occur during five months of the year, carry a lot of powdery sand; the only objection that can be possible raised is that their lubrication requires more attention (1). All these wagons are on two bogies; the system with automatic closing is preferred by us.

(1) *Additional note by Mr. Charignon*, dated 1 September 1911 : " Improvements have been made " which render the lubrication as simple a matter as " in the case of ordinary wagons ".

In Europe, you have hydraulic installations for passing from one gauge to another, and these make the matter easy; in China, the Chang-Tai Railway Company, if I may mention the name, has adopted as solution a very simple and above all very economic installation.

Assume a short piece of narrow-gauge track AB, the centre line of which forms a continuation of the straight line which is the centre line of the standard-gauge track CD. The ends of the two tracks are about 80 metres (88 yards) apart, and they are connected by two converging lines of rail, which have check rails along them on the inside. The length of 80 metres can be reduced; it must, however, be remembered that the smaller the angle between the two converging rails, the less the flanges will grind against those rails or the check rails, and the less those flanges will become worn. It is in fact only the resistance opposed to the flange either by the outer rail or by the inner check rail which gradually forces the wheels nearer together or further apart. The operation is done in the one direction or the other, as in fly-shunting, and it takes less than a minute to make a wagon pass from the one track to the other.

I am unable to give you any details about the design of these adjustable bogies; they are patented and belong to the concessionary company, 9, rue Chauchat, Paris, and to the Baume & Marpent Company, Haine St. Pierre, Belgium.

I have simply wished to draw your attention to an interesting experiment, but several remarks have to be made :

With us, it is a narrow-gauge company which has taken the initiative and adopted rolling stock with adjustable bogies, but

should it not rather be the main railroad which should have such rolling stock, in order to supply it to the different narrow-gauge feeders from whom it receives part of its traffic, and to distribute it amongst them in accordance with their respective needs? This cannot be left to the narrow-gauge lines, for it represents an expenditure which is much too heavy for many of them, and also because they would run the risk of not always having a return freight on the main lines over which the wagons had been sent.

This elimination of the transhipment certainly appears to be the only way of satisfying everybody, as it does away with all handling, that is with all chances of breakage, damage, etc., and eliminates all loss of time caused by transhipment and by delays at the exchange stations.

Accordingly I have the honour to submit to you the following resolution :

" The great railroad companies are requested, with a view to the development of the traffic they get from narrow-gauge lines, to try to eliminate transhipment and to place at the disposal of the narrow-gauge feeder lines, rolling stock with adjustable wheels and axles, which can run on both gauges, as has conclusively been shown to be possible, in China. " (*Applause.*)

Mr. de Burlet. (In French.) — That is very interesting.

Mr. L. G. Gordon, Moscow-Kiew-Voronetz Railway. (In German.) — In Russia the consignor is generally not authorized to attend to the transhipment himself. The charge made for this operation is generally much higher than the figure previously mentioned; it amounts to $^1/_2$ copeck per pood, or about 8*d.* per ton.

Mr. de Burlet. (In French.) — I quoted the cost of transhipment in Belgium. As regards Russia, I have reproduced the information supplied to me by the Russian administrations. On page 36 of my report (1), I express myself as follows : " This special traffic amounts to about 600,000 tons per year; the transhipment costs 1·25 franc (1*s.*) per 10-ton truck." That is 12·5 centimes (1 $^1/_4$ *d.*) per ton. If there is an error, I am not responsible for it. I thought that owing to the great quantity (600,000 tons per year), very favourable results had possibly been attained. Consequently, we can but take note of the correction which has just been made.

Mr. Waechter, Vering & Waechter Company, Germany. (In German.) — In Wurtemberg, the regulations require every carrying-truck to be fitted with a special brake. In spite of this regulation, no type has yet been found which does not give trouble. The brake can only be at a small height above the ground; consequently, it is often damaged by the stones of the roadbed or at the level crossings, and its action is often unsatisfactory; it only acts on one or at most two of the axles of the bogies. Accordingly, we have tried to make other arrangements, and the regulations at present require every carrying-truck to be preceded by a wagon with ordinary brake. This measure has given good results. With us it is not

(1) See also *Bulletin of the Railway Congress,* 1910, January, p. 464.

prohibited to have several such carrying-trucks on one train, while the contrary is the case in Austria. In the case of certain articles of a particularly fragile nature, such as pottery, we come to an agreement with the manufacturers to attend to the transhipment themselves.

Mr. Jesser, *principal secretary*. (In German.) — Allow me to add a short remark to the report. It so happens that the answers do not express the fact that after all carrying-trucks form a good means of communication between standard-gauge and narrow-gauge lines. The only answer given in this connection is that of the administration of the Prussian State Railway, which considers that carrying-trucks do not suffice for transhipment purposes, as their use is limited to certain well-defined cases. Now there is a number of smaller lines where the regulations concerned are not so inconvenient as has been asserted.

In Austria, as Mr. von Ziffer has already informed us, only one carrying-truck is allowed per train. In many cases that suffices perfectly. If we consider the small lines where perhaps three or four trains run in each direction per day, which do not cater for rich industrial distructs, we find that from 1,000 to 1,200 wagons can be hauled per year. In Austria, these wagons are taken by mixed trains. The train may very well include passenger carriages, without this preventing 30,000 to 40,000 kilograms (66,000 to 88,000 lb.) of goods from being hauled per day. In Austria, carrying-trucks are not braked, and as far as I know, no attempts have yet been made to utilize this safety device. This, moreover, has not led to any trouble. It is true that the speed is limited to 15 kilometres (9·3 miles) per hour; but this again does not inconvenience short lines, for there are sundry other reasons against adopting a higher speed limit, particularly if the line is laid wholly or in part on the highway, or if there are sharp curves, such as are necessary if the cost of construction of lines of this kind is to be kept low.

Mr Waechter has stated that there may be several carryings-trucks on one and the same train; it would be interesting to hear how those trucks are coupled up. The report gives us no information about this point; probably the reporter has received no information about it.

Mr. Waechter. (In German.) — As regards the coupling up of carrying-trucks, I may inform you that stiff coupler bars of different lengths are used. They are placed between the trucks and connected in the ordinary way, by means of a knuckle pin passing through a hole and kept in place by a cotter.

Colonel Bonham Carter, Madras & Southern Mahratta Railway, India. — In India, there are four different gauges and transhipments therefore tend to be more numerous than if there were only two as in Belgium.

The Government fixes maximum rates for all railways based on mileage plus terminals and authorizes an optional charge as for three miles for transhipment at a junction where there is a break of gauge.

As a general rule, no charge is made for transhipment but when a charge is levied it is included in the through rate and not shown separately.

Mr. de Burlet. (In French.) — The rate for 3 miles.

The President. (In French.) — The charge is included in the general rate.

Mr. de Burlet. (In French.) — The distance charged for is increased by 3 miles, that is about 5 kilometres.

The President. (In French.) — Quite so.

Mr. de Burlet. (In French.) — But it is a single charge.

Colonel Bonham Carter. — The rule that no charge is made is not absolute but a charge is exceptional.

Mr. Chassin, French Southern Railway. (In French.) — The information which has just been given is very interesting from the point of view of new countries where new lines are being built, but I do not think that in our European countries, where there are lines in all directions, it is possible to use wagons with bogies with adjustable wheels and axles on narrow-gauge lines.

In my opinion, transhipment is necessary and will always be necessary. What is required, is to find practical means for transhipping bulk goods as cheaply as possible.

I show on the blackboard the design of a self-discharging wagon with a bottom of inverted V shape, which makes it possible to unload bulk goods such as ore, coal, phosphate, etc., with great rapidity. The wagons are brought on to a raised track, the side doors are opened and the goods fall either into hoppers or directly into a standard-gauge wagon. The angle at the bottom is about 30°.

The operation is very easy. A whole train can be emptied in a minute. That is a simplification in the handling which effects a considerable saving.

We have a project of constructing hoppers capable of taking 2,500 to 3,000 tons; but that can only be done in the case of a very big traffic which such stores would help to equalize.

As regards tracks with three rails, we have about 150 kilometres (93 miles) of such tracks on our lines; but it is nearly impossible to work simultaneously with rolling stock of both gauges. One does not yet know any practical method of traction on such three rails; there is always a sideway pull which leads to risk of derailment.

Switches are another great difficulty.

On our lines, the switches are constructed for three rails, and at a given moment one can operate with the standard gauge only.

About twenty years ago, a special commission made experiments in order to determine the resistance of trains on sharp curves. Experiments were made with standard-gauge trains weighing 125 tons (123 English tons) and with narrow-gauge trains of the same weight. The conclusion arrived at was that on curves having a radius of 150 metres (7 1/2 chains) the resistance is greater in the case of the standard gauge and, consequently, operation costs more.

We have also had switches constructed for the four-rail track. These switches cost 10,000 francs (£400) each and it was necessary to give up this idea.

Mr. de Burlet stated that in Belgium 25 centimes per ton (2·44*d.* per English ton), was paid for the transhipment. In France, this averages 30 centimes (2·93*d.*

per English ton) for all goods. It is necessary to try and reduce the labour by putting up cranes, travellers, etc., to do the transhipment.

Mr. Plocq, Société générale des chemins de fer économiques, France. (In French.) — I am an old narrow-gauge operator and I should like to answer the previous speaker who seemed to condemn the four-rail system rather severely. I do not claim that this system can be applied everywhere, but this is what we have done in France.

The French Northern Railway had a standard-gauge line from Noyelles to St. Valéry. The *Société générale des chemins de fer économiques* of France added at each end a narrow-gauge line, and Mr. Emile Level, who was then manager of the *Société*, proposed to the French Northern Railway that it should lay a narrow-gauge line between Noyelles and St. Valéry (so as to ensure the continuity of the narrow-gauge system) and that it should also lease to him the operation of the standard-gauge line between those two points.

Since 1887, the service of the French Northern has been carried out by the *Société générale des chemins de fer économiques*. The narrow-gauge rolling stock is fitted with three buffers, or else a special coupling-up wagon is used.

This system which has now been in use for twenty-three years has never given rise to any trouble.

Mr. Chassin. (In French.) — There is a misunderstanding.

I did not wish to condemn the operation of certain short four-rail sections, for that is a question of kind and it may be very useful to do so ; but I assert that as a general rule when a light railway is to be built, it is better to have a narrow-gauge one, as Mr. de Burlet stated in his report, and to avoid the complication of three or four rails, which renders operation difficult.

Mr. Plocq. (In French.) — I quoted a particular case.

The President. (In French.) — Mr. Suarez, delegate of the Bolivian government, has requested me to inform the members of this section that he is going to distribute among them copies of a note he has drawn up, which will be at their disposal this afternoon.

Mr. de Burlet. (In French.) — In our country, there is no regulation preventing the presence of more than one carrying-truck in a train.

Mr. Jesser has asked me whether this information supplied to me shows that sometimes more than one motor truck is in a train. I have received no definite information about this point, but I am convinced that there are whole trains of motor trucks, if I may judge by the number of trucks which exist on certain lines and by the importance of the traffic which has to be dealt with.

Mr. Chassin has spoken about three-rail and four-rail lines.

The three-rail line shows disadvantages as regards traction, and in our country we hardly use it any more.

When we have to equip a narrow-gauge section for the standard gauge, we prefer to have four rails as soon as the section is no longer a very short one.

We find this system works well.

Mr. Plocq has already answered Mr. Chassin's somewhat summary condemnation. Mr. Chassin stated : " We have also had switches constructed for the four-rail track. These switches cost 10,000 francs (£400) each and it was necessary to give up this idea."

In Belgium, we have had four-rail sections during the last ten years; they work very well and accommodate a considerable amount of traffic.

In the neighbourhood of Liége, we have connected up a coal pit which should give us about 75,000 tons per year; hence, it was worth while making a four-rail track. No doubt, as Mr. Chassin remarked, the track appliances are rather expensive; but such a large traffic fully justifies the expenditure. In the case I refer to, the service is carried out under excellent conditions. We have among us the very able manager of the company which operates this four-rail section, Mr. Philippe, and I feel convinced he will not contradict me when I say that everything goes very well.

Hence I do not wish that the section should remain under the impression that a four-rail track is utopian; thus I confirm Mr. Plocq's statement. It is a reality which may render great services. It is evident that each individual case must be carefully examined, and the cost compared with the receipts to be expected. I may add that the price of our four-rail track appliances is appreciably lower than the figure mentioned by Mr. Chassin.

Mr. Reverdin, who has to do with the light railways of Geneva, wished to be present at our meeting; he is, however, engaged at another section where he is very ably carrying out his duties as secretary-reporter. He has requested me to inform the section what is being done on the Geneva lines. He says :

" In 1896, the narrow-gauge railway company, of which I was then manager, adopted carrying-trucks in order to convey to the spot, in the National Swiss Exhibition, the standard-gauge wagons, so as to avoid transhipment at Cornavin station. In a few weeks before the opening, 240 wagons were conveyed in this way, and after the closing, 290 wagons.

" Branch lines have been constructed since in order to cater for the gas works of the city of Geneva and the commune of Plainpalais, the mills, the engineering works, the tileworks, the provision stores, etc.

" In the *Bulletin technique de la Suisse romande* of 25 July 1905, you will find details about the traffic in question.

" It may be mentioned, as of interest, that this system makes it possible to extend the benefit of the standard-gauge system to establishments whose position was such that it was impossible to connect them with a station by means of a standard-gauge line.

" From the point of view both of gradients and of curves, the narrow-gauge track, owing to its flexibility, when carrying-trucks are used, makes it possible to reach the works, even if they are very badly placed for this purpose.

" The carrying-trucks make it possible to have curves with a radius of 15 metres ($^3/_4$ chain).

" In 1896, the company had six pairs of them in use.

" In 1909, it had eighteen pairs.

" In 1896, it began by carrying 837 wagons in three months.

" The number of wagons then increased as follows : 3,220 wagons in 1898; 5,453 wagons in 1904; 7,500 wagons in 1909.

" There are twelve branches in use; the total tonnage exceeded 90,000 in 1909.

" The transport is generally over short distances, 3 to 4 kilometres (1·8 to 2·5 miles) from the station.

" However, about a hundred wagons (food, wine), are carried a distance of 18 kilometres (11 miles).

" The profit is about 2 to 3 francs (1*s.* 7 $^1/_2$*d.* to 2*s.* 5*d.*) per wagon carried, any distance."

The statistical information supplied by Mr. Reverdin is very interesting; it also confirms what I stated in my report, namely that since the Congress took up the question of transhipment, the use of carrying-trucks and carrying-wagons has become very extended. That proves that the companies think that this practice is economic and to be recommended. There is nothing like experience in order to solve questions of this kind.

The four-rail track is not applicable in a general way; but in special cases this solution is also very practicable and very useful.

The President. (In French.) — As nobody else wishes to speak in the general discussion, we now come to the conclusions.

Mr. de Burlet. (In French.) — These are the conclusions which I have the honour to submit for your approval :

" Experience has shown that transhipment from truck to truck by the level method does not constitute, for exchange traffic between lines of narrow-gauge and the main railroad, a too onerous charge in ordinary cases."

The President. (In German.) — We will take, with your approval, the clauses one after the other. If you have any objection, I will gladly hear it.

As nobody wishes to make any remarks, you agree to adopt the text of this first clause.

Mr. de Burlet. (In French.) — The next clause runs as follows :

" Nevertheless when, in certain special cases, or for certain goods, it is found indispensable to reduce the said charge, carrying-trucks or carrying-wagons, sunk or raised track arrangements, the use of tip-wagons and the partial equipment of the narrow-gauge line with a track of three or four rails, constitute solutions which experience has proved to be useful and practicable. "

I myself propose an amendment to this wording.

I had retained the three-rail track, as several administrations stated that they used them. Hence, I did not wish to condemn them. But as information unfavourable to the three-rail track has been given here, that item might be struck out. It was in a very conciliatory spirit that I had retained the three-rail track. We then should say : " ... of the narrow-gauge line with a track of four rails."

Mr. Campiglio. (In French.) — I ask that the original wording should be retained.

Mr. Jesser. (In German.) — Cases might arise, if the difference between the two gauges was small, when it would become technically impossible to lay four rails,

and in order to allow for such special cases, it would perhaps be better to let us retain the words : " ... three or..."

Mr. de Burlet. (In French.) — Under these conditions, I support the request of my honourable colleagues and propose that the original wording should be retained.

— Adopted.

Mr. de Burlet. (In French) — Two amendments have been brought forward. Mr. Campiglio proposes to add to the conclusions a clause 3 worded as follows :

" In investigating the question whether it is advisable to adopt the special installations mentioned in the preceding clause, consideration has to be given to the quantity and to the nature of the goods, to the distance they have to be carried and to the conditions relating to the exchange or hire of the rolling stock used for those goods (dues which have to be paid, time of utilization of the wagons, etc.)."

I allow myself to remark to my honourable friend Mr. Campiglio, that in my report, the last page of which contains a summary of it, consideration has already been paid to these different statements : the quantity and the nature of the traffic, the mileage, the conditions affecting the interchange of rolling stock, etc.

Each time I described a system of transhipment, I stated under what particular circumstances such and such a company applied it. Is it necessary to return to this in the conclusions, or does it suffice to mention the different special arrangements which have been adopted?

There is only one point which I have not mentioned in my report, and that is, the exchange and hire of rolling stock, and that I think is what is troubling Mr. Campiglio.

The honourable member states that the administration of the main railroad places the loaded wagons at the disposition of the narrow-gauge line, and that it allows the latter a certain time for the transhipment. Mr. Campiglio complains that that time is too short in Italy and he wishes to call the attention of the Congress to the somewhat Draconian regulations of the administration of the Italian State Railway. But it seems to me rather difficult to introduce this criticism in the conclusions.

Mr. G. Level, Société générale des chemins de fer économiques, France. (In French.) — It is a question of giving facilities.

Mr. Campiglio. (In French.) — We might say : " Independently of the conditions of quantity and of transport, attention has to be paid to the mileage of the goods and the conditions to be specified concerning the exchange or hire of rolling stock."

Mr. de Burlet. (In French.) — Strictly speaking there is neither exchange nor hire. Rolling stock is placed on the tranship sidings so as to be at the disposition of the narrow-gauge line for a certain length of time, that is all. It is, merely, a question of the time allowed for loading or unloading.

I repeat, it is difficult to introduce this at all accurately in the conclusions. One could say : " It is desirable that the great railroad companies should facilitate the tranship operations."

That is evidently what we all hope.

The President. (In French.) — Quite so; in a general manner.

A delegate. (In French.) — By increasing the time for which no charge is made.

Mr. de Burlet. (In French.) — We should then say :

" It is desirable that the main railroads should facilitate the transhipment operations by increasing as much as possible the time allowed therefor."

The President. (In French.) — I think that it is agreed that this wording should be adopted. (*Signs of approval.*)

Mr. de Burlet. (In French.) — The second amendment is by Mr. Charignon, who proposes that the following clause should be added to the conclusions :

" The great railroad companies are requested, with a view to the development of the traffic they get from narrow-gauge lines, to try to eliminate transhipment and to place at the disposal of the narrow-gauge feeder lines, rolling stock with adjustable wheels and axles, which can run on both gauges, as has conclusively been shown to be possible, in China."

I have some remarks to make about introducing this clause into our conclusions. In the first place, this system is comparatively new. How long has it been in use in China?

Mr. Charignon. (In French.) — For two years.

Mr. de Burlet. (In French.) — It is very little known in Europe. I do not know that a European company or even an American company has tried it. This system has not been described in any report or paper. Under these conditions, it appears to me to be risky to give any advice to companies, whether large or small, without having available a more complete report than the verbal communication we have had today.

Hence, I propose not to introduce in our conclusions this advice which it is proposed to give to large companies. This is always a very delicate matter, and I think we should go counter to the most elementary prudence if we now already took under our official patronage a system which has not yet proved its efficiency. I think that this would, moreover, be against the very wise rules adopted by the Congress.

As for me, I accordingly am unable to vote for this amendment; but as the communication made to us is of very great interest and it is not advisable that it should remain unnoticed, I propose to add to our conclusions this clause :

" The section has taken note, with interest, of the communication made as to the use, on a Chinese railway, of a truck with axles on which the wheels are adjustable."

Mr. Chassin. (In French.) — We might ask that the question should be brought before the next Congress.

Mr. de Burlet. (In French.) — That will form part of our conclusions and it will be for the Permanent Commission to place this question on the agenda, if it considers this to be advisable.

A delegate. (In French.) — But the section can express a desire about this subject.

Mr. Chassin. (In French.) — I propose the wording : " The section expresses the wish that this question should be placed on the agenda of the next session."

Mr. de Burlet. (In French.) — We have to propose a wording to the Congress, which it must consider. Therefore we must say : " The Congress..." and not : " The section..."

I accordingly propose to say :

" The Congress has taken note, with interest..."

Mr. G. Level. (In French.) — Gentlemen, I think you will be interested to hear that a very detailed technical description of this system has been published in the *Revue générale des chemins de fer* (1).

— The wording proposed by Mr. de Burlet is adopted.

Mr. de Burlet. (In French.) — Do we agree to adopt the following wording :

" It is desirable that the study of this system should be continued, and that information thereon should be brought before the next meeting of the Congress." (*Signs of approval.*)

These are accordingly the definite conclusions to be submitted to the general meeting for approval :

" Experience has shown that transhipment from truck to truck by the level method does not constitute, for exchange traffic between lines of narrow-gauge and the main railroad, a too onerous charge in ordinary cases. " Nevertheless when, in certain special cases, or for certain goods, it is found indispensable to reduce the said charge, carrying-trucks or carrying-wagons, sunk or raised track arrangements, the use of tip-wagons and the partial equipment of the narrow-gauge line with a track of three or four rails, constitute solutions which experience has proved to be useful and practicable. It is desirable that the main railroads should facilitate the transhipment operations by increasing as much as possible the time allowed therefor.

" The Congress has taken note, with interest, of the communication made as to the use, on a Chinese railway, of a truck with axles on which the wheels are adjustable. It is desirable that the study of this system should be continued, and that information thereon should be brought before the next meeting of the Congress."

— Adopted.

The President. (In French.) — Gentlemen, we have concluded our labours.

Mr. de Burlet. (In French.) — Gentlemen, I think we ought not to separate without expressing our sincere thanks and our best wishes to our distinguished president who has taken enormous trouble to study the very special questions included among our agenda and who has presided over our discussion with great skill and with perfect courtesy. He has undertaken a large additional amount of work in translating into German and into English the French speeches; he has thus largely contributed to the good progress of our labours. (*Long applause.*)

*

(1) 1909, December, p. 466. — A description of this system is also given in the *Génie civil*, 2 October 1909, and in the *Annales des ponts et chaussées*, 1909, November-December, p. 19.

The President. (In French.) — Gentlemen, I thank you. I have done all I could to conduct your labours as well as possible and I am happy that I have succeeded in doing this to your satisfaction.

Allow me to say, in my turn, a few words to those who prepared the work for our section. I do not think we can separate without expressing to Messrs. de Burlet, Jesser, Plocq and Quarré, our thanks and our cordial congratulations, for the very interesting and very instructive reports they have submitted to us. (*Loud applause.*)

DISCUSSION AT THE GENERAL MEETING

Meeting held on 15 July, 1910 (morning).

Mr. P. WEISSENBACH, president, in the chair.

General secretary : Mr. L. WEISSENBRUCH.

First assistant general secretary : Mr. MÜRSET.

Second assistant general secretary : Dr. A. BONZON.

Mr. von Ziffer, *vice-president of the 5th section*, read the

Report of the 5th section.

(See *Journal de la huitième session*, No. 8, p. 7.)

" Mr. de Burlet gave a summary of his report. The question of transhipment had already been formerly considered by the Congress, and no doubt it would again be considered in the future. It was connected, in fact, with the question of the gauge to be selected when it was proposed to build a secondary line. The narrow gauge presented, from the point of view of prime cost, an indisputable advantage over the standard gauge; but on the other hand, it made the transhipment of goods necessary. Was this disadvantage sufficiently serious to determine the selection of the standard gauge, even at the cost of a large expenditure? The answer would be in the negative in most of the cases; in fact on the one hand the passenger traffic, which generally yielded the more important part of the receipts, was not affected by it, and on the other as for goods, it represented an expenditure which in most cases hardly exceeded 15 to 25 centimes per ton (1·46*d.* to 2·44*d.* per English ton).

" The report contained details of six separate methods for the transhipment of goods between lines of different gauges :

" 1° Transhipment by hand, on tracks at the same level. This was the method which involved the fewest fixed installations;

" 2° Transhipment on sunk or raised tracks. This method was sometimes supplemented by the use of tip wagons or hopper-bottom wagons;

" 3° Transhipment by means of gantry cranes, chiefly used in the case of rough timber, machinery, blocks of stone, and

generally for goods consigned in the shape of indivisible lots of large weight;

" 4° The transfer, on suitably-arranged tracks, of the body of a wagon of the one gauge on to the underframe (with bogies) of one of the other gauge. This system, for which ordinary European rolling stock was not suitable, was in use in the United States;

" 5° Carrying-trucks and carrying-wagons. This system was applied on a large scale, particularly in Germany;

" 6° The transformation of the narrow-gauge line into a two-gauge line (track with three or with four rails).

" Mr. de Burlet gave a summary of a note he had received from Mr. Reverdin, of Geneva, on the subject of the carrying-trucks introduced, in 1896, on the lines of the " narrow-gauge " company, on the occasion of the Swiss national exhibition at Geneva. He noted that in 1909 he had conveyed, by means of eighteen pairs of trucks, more than 7,000 wagons containing 90,000 tons of goods between the Geneva-Cornavin station (Paris-Lyons-Mediterranean Railway) and sundry industrial sidings.

" Mr. de Burlet concluded with the statement that although the system of transhipment by hand, on tracks at the same level, was the system employed by far most frequently, one nevertheless had to recognize that in special cases carrying-trucks or carrying-wagons, sunk or raised tracks, the use of tip-wagons and of hopperbottom wagons, the transformation of the narrow-gauge line into a two-gauge line constituted solutions which had been successful in practice.

" Mr. Campiglio (*Italian local railway Union*) mentioned that in Italy the main lines only allowed a very short time for the return of any of their wagons handed to the narrow-gauge line for transhipment, and required payment of demurrage when this time was exceeded. According to Mr. Campiglio, this was injurious to the traffic, and he asked that his remark should be mentioned in the conclusions which were to be submitted to the general meeting.

" Several members of the meeting then interchanged views in order to ascertain whether, in their respective countries, the cost of transhipment was included in the tariffs, or was made the subject of a separate charge. The explanations exchanged showed that in most countries it was charged for separately; but the consignor or the consignee could avoid these charges by having the transhipment effected by his own employees, if he saw fit to do so. In British India, the charges in question were included in the tariff; the usual way of doing this was to increase the distance to be charged for by 3 miles (about 5 kilometres).

" Mr. du Beaufret (*Bône-Guelma Railway, Algiers*) gave some particulars about an important traffic of phosphates (300,000 tons per year). Several proposals for the installation of special devices in order to facilitate transhipment had been considered, but as yet no result had been arrived at.

" Mr. Charignon (*Chinese government*) informed the meeting that in China there was a narrow-gauge line, which brought a considerable amount of coal to the Pekin-Hankow main line; in order to avoid transhipment, wagons with axles on which

the wheels were adjustable were used. He gave some particulars about this system, and stated that this had now been in use for about two years, with satisfactory results.

" After some remarks by Messrs. CHASSIN (*French Southern Railway*), PLOCQ (*General French Light Railway Company*) and DE BURLET (*reporter*), as to the practical working of lines with three and with four rails, the section decided to submit the following conclusions to the general meeting."

The President. (In French.) — The following are the

DRAFT CONCLUSIONS

" Experience has shown that transhipment from truck to truck by the level method does not constitute, for exchange traffic between lines of narrow-gauge and the main railroad, a too onerous charge in ordinary cases.

" Nevertheless when, in certain special cases, or for certain goods, it is found indispensable to reduce the said charge, carrying-trucks or carrying-wagons, sunk or raised track arrangements, the use of tip-wagons and the partial equipment of the narrow-gauge line with a track of three or four rails, constitute solutions which experience has proved to be useful and practicable. It is desirable that the main railroads should facilitate the transhipment operations by increasing as much as possible the time allowed therefor.

" The Congress has taken note, with interest, of the communication made as to the use, on a Chinese railway, of a truck with axles on which the wheels are adjustable. It is desirable that the study of this system should be continued, and that information thereon should be brought before the next meeting of the Congress."

Mr. d'Abramson, Russian State Railway. (In French.) — The system of axles with adjustable wheels is also used in Russia with good results, on the South Western Railway, on the Vistula Railway and on the Warsaw-Vienna Railway. Hence it is a mistake to say that this system is only in use on a Chinese railway.

Mr. Blum, Prussian State Railway. (In German.) — It is also used in Germany.

Mr. von Ziffer. (In German.) — There is no mistake, or at least a delegate of the Chinese railways attended the meeting and talked about this system. I know that the Russian railways and the Austrian railways also have wagons of this kind; each of these countries has about 300 and there are also some in use on the new lines in Bukowina. The delegate of the Chinese railways did not give further details; he said that the invention was patented. I do not know what the difference between the two gauges in China is. If this system could be readily used on the Russian and Austrian lines, this is due to the fact that the difference is very small. But if there is a great difference in China, a wide gauge of 1·6 metres (5 ft. 3 in.) and a narrow gauge of 740 millimetres (2 ft. 5 $^{1}/_{8}$ in.), I do not understand how it is done. That is the reason why we did not mention the Russian wagons.

Mr. d'Abramson. (In German.) — Would it not be advisable to mention the other railways so as to avoid the same misun-

derstanding with those who do not know what the president of the 5th section has said?

Mr. von Ziffer. (In German.) — If you make a proposal to this effect, I do not think that it will be opposed by us.

Mr. Weissenbruch, *general secretary.* (In French.) — The last phrase might be modified as follows :

" It is desirable that the study of this system, which is also used in Russia, where it has given good results, should be continued..."

Mr. de Burlet, *reporter.* (In French.) — We could but reproduce and analyse the information brought before the section.

The list of questions relating to the subject of transhipment was sent to all the railways, including the Russian and the Austrian railways. None of them supplied any information about the use of such adjustable wheels and axles.

It was only during the discussion that our colleague, the delegate of the Chinese government, made a communication which we thought of interest and have mentioned in the conclusion.

It seems to me a matter of difficulty to state in the conclusions that the system of extensible axles has given good results in Russia, as no information to this effect was given to the 5th section, nor was any discussed.

I, however, see no disadvantage in adding to the proposed conclusions and mentioning that the system is also used in Russia; but we must refrain from saying that it has given favourable results.

Mr. d'Abramson. (In French.) — I agree.

Mr. Weissenbruch. (In French.) — We might say : " It is desirable that the study of this system, which has received applications in Russia and in Austria..."

Mr. Blum. (In French.) — And in Germany.

Mr. Weissenbruch. (In French.) — Or still better : " ... which has also received applications in other countries..."

Mr. d'Abramson. (In French.) — And between brackets put : " Germany, Austria, Russia." (*Approval.*)

The President. (In French.) — These are then the

FINAL CONCLUSIONS.

" Experience has shown that transhipment from truck to truck by the level method does not constitute, for exchange traffic between lines of narrow-gauge and the main railroad, a too onerous charge in ordinary cases.

" Nevertheless when, in certain special cases, or for certain goods, it is found indispensable to reduce the said charge, carrying-trucks or carrying-wagons, sunk or raised track arrangements, the use of tip-wagons and the partial equipment of the narrow-gauge line with a track of three or four rails, constitute solutions which experience has proved to be useful and practicable. It is desirable that the main railroads should facilitate the tranship operations by increasing as much as possible the time allowed therefor.

" The Congress has taken note, with interest, of the communication made as

" to the use, on a Chinese railway, of a " truck with axles on which the wheels " are adjustable. It is desirable that the " study of this system which has also " received applications in other countries " (Germany, Austria, Russia, etc.) should " be continued, and that information " thereon should be brought before the " next meeting of the Congress."

— These conclusions were adopted by the general meeting.

NOTE

ON THE UTILITY OF STUDYING THE QUESTION OF FREIGHT CAR INTERCHANGE AND DEMURRAGE,

By W. F. ALLEN,

GENERAL SECRETARY OF THE AMERICAN RAILWAY ASSOCIATION.

INTERCHANGE OF FREIGHT CARS AND DEMURRAGE.

General.

In considering the subject of " freight car interchange and demurrage ", as presented in this report, it should be stated in the first place, that it was included in the programme of the Congress at the request of the American members of the International Commission, and that the questions as formulated were drawn up especially for the purpose of eliciting information of value in the solution of the intricate and very important car service problem encountered in North America.

To the members of the Permanent International Commission who authorized the issuance of the circular, and to those officials who have so courteously furnished the very complete information sent in reply, the thanks of the American members of the Congress are due and are most cordially tendered.

The reports received are from administrations which operate in all about 430,000 miles of railway and possess about 3,800,000 freight cars. Of these 250,000 miles and 2,200,000 freight cars are in North America and about 182,000 miles and 1,600,000 cars elsewhere.

It is an interesting fact to note that the number of freight cars per mile of road, taken as a whole, is about the same on the North American railways as in the rest of the World, that is, a little less than nine cars to the mile. In a few instances, the equipment is much greater, and in some cases as high as thirty cars to the mile. These figures of cars and miles were not obtained directly from the reports but from other fairly reliable sources.

The question presented in North America is that of evolving the most efficient method of handling on a uniform basis 2,200,000 freight cars, that move freely over 250,000 miles of railways and serve over 80,000 communities many of which have

numerous substations The extent of the territory traversed by these railways is about 3,000 miles east and west and an equal distance north and south.

These 2,200,000 cars have over nine hundred different owners, although about 80 per cent of them belong to fifty-six companies. From 25 to 50 per cent of this equipment is constantly in use upon the lines of roads other than those to whom the cars belong From these figures the magnitude and complexity of the situation in North America may be understood.

The conditions as compared with those on the European Continent are mitigated however by the fact that there are but two lines of custom houses to be passed (between Canada and Mexico respectively and the United States), that the same language is spoken on both sides of one of these lines and that all of the governments are disposed to facilitate commercial intercourse without unnecessary obstruction.

One detail closely related to this general topic — that of the best method of distributing freight cars locally upon the lines of each company — has not been included in this report. The conclusion on that subject reached at the fourth session of the International Railway Congress, held at St. Petersburg, in 1892, was as follows :

" The distribution of rolling stock is made generally under conditions justified by the geographical characteristics of each railway system and appropriate to the nature of its current of commercial traffic."

No better statement can be made today, and no generalization of the methods employed, however interesting, would be of much practical value since each system must use the method best adapted to its own local requirements. However, those who may wish to study this phase of the subject, will find in the excellent paper of Mr. Richter, the distinguished reporter to the fourth session of the Congress, a very complete statement in detail of the practices in force on European railways in 1892. It will be found in the third volume of the Proceedings of that session. It does not appear that many important changes have been made in these practices since 1892.

Before proceeding to the consideration in detail of the subjects of this report, the following general statement should be noted.

The responses exhibit the fact that the same problems, more or less troublesome, exist everywhere. In some of them, information is given which is not strictly of the nature of a reply to the questions asked ; but when such information relates to the general subject and is of an interesting character it has been included. It is evident, in a few instances, that the questions have been misinterpreted and in some, the reply to one question has been included in the answer to another. An attempt has been made to note all such cases by cross references.

Ab Initio every freight car may be assumed to be loaded in a location where the track upon which it stands is the property of the company which also owns the car. In passing beyond the terminus of that road to the lines of another road, whether of the same country or not, the vehicle becomes technically a " foreign car " and the

company which is then in control of its movement is under certain obligations to its owners for its use, its physical care, and for its prompt return either loaded or unloaded. The rule everywhere is that a foreign car must be kept in general repair by the company which holds it, certain work of a specified character being billed against the owner.

The agreements under which foreign cars are taken care of physically are not, however, within the scope of this report, which is confined to the subject of their interchange use and undue detention and the charges accruing therefrom. For the purpose of distinguishing them, these charges are herein named as " car hire " and " demurrage ".

By " car hire " is meant the amount which the administration using a car pays to the owner for its use, whether the payment is based upon the distance travelled, or is so much a day, or both. Included under this head is the penalty charge exacted for the undue detention of a car upon its lines by a foreign road and similar charges imposed when the car is missent or misrouted on its return journey.

By " demurrage " is meant the amount which the railroad holding the car, whether its owner or not, exacts from the shipper or consignee for its undue detention, when it has been placed for loading or unloading, this charge covering the occupancy of the tracks as well as the use of the vehicle. Money collected for demurrage accrues to the benefit of the owner of the track, who in turn, in the case of a foreign car, settles with its owner for its use.

The tendency of the shipper and of the consignee to take an unnecessary amount of time to load or to unload the car, si everywhere recognized as an evil which if permitted to go unchecked would greatly lessen the efficiency of railway operation.

The word " demurrage " has been employed in some of the replies to the circular of inquiry in referring to detentions caused by railroad companies as well as by customers; but it has not been possible to so use it in this report without confusion. Some liberties have therefore been necessarily taken with the exact wording of the reports received, for which the writer wishes to duly apologize.

The summaries of the replies refer to other countries than North America except where otherwise stated.

Freight car interchange.

It is evident from the replies received that in all parts of the world that railway authorities have decided it to be essential to the prompt and economical transportation of freight by rail, that its passage beyond the termini of roads and the boundary lines of countries, must not make necessary the unloading and reloading of freight cars, but that the contents of fully loaded cars [1] must be transported from their

[1] Whenever the word " car " is used in this report it refers to vehicles used for the transportation of freight (goods, merchandise, coal, etc.) and not to passenger carriages.

points of origin to destination without break of bulk. Shipments of less than car load lots may or may not be economically reloaded, depending upon the quantity and character of the lading and its proportion to the full loading capacity of the car. The regulations as to what this proportion should be vary from 20 to 33, 40 and 50 per cent of the carrying capacity of the car. Generally a car is considered as if it were sufficiently loaded when payment has been made for the required proportion whether the lading actually occupies the space called for or weighs the amount stated. The minimum lading permitted varies sometimes with the distance the car is to be transported.

From the standpoint of the shipper and to a certain extent of a railway station agent, a car is merely a vehicle of transportation without regard to its ownership, and the tendency is to place a waiting load in an empty car no matter in what direction the movement is to be made.

If all cars were of the same ownership, the direction of their loaded movements would of course be a matter of indifference, but the ownership of cars by separate companies or administrations presents another phase of the question. These companies desire to retain the cars upon their own lines in order that they may earn the interest on their cost together with the interest on the considerable investment in other property which is part of their freight equipment. When the car is not available the earning capacity of all of this property is dormant.

The general method of equalizing these conditions is to require payment to be made to the owner for the use of the car when it is employed upon another system.

Two factors are commonly recognized as entering properly into the rate fixed for car hire, viz : the distance the hired car is transported and the length of time it is used. For the purposes of this report the term " mileage " is used in referring to the distance charge and the term " per diem " for the daily charge.

In some calculations of mileage, the car is considered as the unit without regard to its size or loading capacity. In others the unit is the axle so that a four axle car earns twice as much rental per mile run as a two axle car, and in still others the rate varies with the tonnage capacity. Sometimes the mileage rate is graduated, as in Great Britain, where the rate per mile for distances of over 278 miles is less than one half that charged for distances of 58 miles and under. In South America, the mileage rate varies according to the loading capacity of the car and no per diem rate is exacted. In North America, no mileage is paid for the use of the ordinary freight cars belonging to railroad companies, but it is paid on privately owned cars.

The unit of time upon which in general, the per diem rate is based, is the full period of twenty four hours; but in some parts of the continent of Europe, the unit is a period of twelve hours, and a few instances a rate per hour is charged. In East India and also in South Africa, the charge for time is by the hour and the rate is fixed at a certain price per ton on the loading capacity of the car, which capacity varies from twelve to thirty five tons avoirdupois.

In North America, the record is kept by dates : that is to say, the per diem rate for

the entire following period of twenty four hours is charged against the road which holds the car at midnight. This rate is so much per day without any mileage charge and without regard to the loading capacity, which varies from 20 to 50 net tons. Formerly the uniform charge was six tenths of a cent per mile run. A few of the larger lines experimented in 1888 and in 1893-94, with what was called a " mixed per diem " the rate in 1893-94 being one half of a cent per mile, plus 6 cents per day; but this experiment was not followed by the other lines and was abandoned after a few months trial. In 1902 a " straight per diem " was adopted by all the lines, and that method has been in use for the past seven years at various rates of charge.

While the rates reported affect all cars alike for the greater part of the freight equipment of the World yet certain classes, such as refrigerator cars, are in service upon many of the lines and receive exceptional treatment. These classes form, however but a small proportion of the total equipment and need not be considered in any general review of the subject. Statements of the details of these special arrangements will be found in the text of some of the accompanying responses. The regulations for the interchange service of passenger cars which were given in some of the replies are not generally reported herewith, as they are foreign to the subject under consideration, but in a few instances, they are closely interwoven with the information concerning freight cars and have been noted.

The reports as to the methods of these operations on the railways of Germany, were made prior to the formation of the pooling agreement which took effect on 1 April, 1909. They are now, consequently, modified by the terms of that agreement a copy of which is presented as a supplement to this report. These old regulations are of special interest because they show the arrangements superseded by the pooling agreement and which presumably were considered the best known methods while they were in force.

The Russian system of interchange of car for car, in countries where the traffic is of a nature that permits equalization of movement, appears to have ideal advantages second probably only to those of a practicable pool. Whether it will be possible to maintain this method of working satisfactorily in case an extensive system of branch railroads should be developed as feeders of the Trans-Siberian line and at its extreme eastern terminii, is perhaps an open question. The Russian tracks being of a different gauge from those of the rest of Europe, the situation is not complicated by the presence of foreign cars; although some experimental arrangements for a limited interchange movement of these cars are now being tried.

An equalizing method of interchange is also provided for in the Rules and Regulations of the Indian Railway Conference Association.

The agreement between the Southern Railway of France and the Paris-Orleans Railway disregards differences on balances unless in excess of three hundred cars, and a similar agreement is in force in the Italian-French traffic via Modena-Vingtimille.

In South Africa, the cars of the Cape Government Rys. and those of the Central South African Ry. are pooled for through traffic each furnishing a prescribed number of vehicles, no car hire being levied.

Similar arrangements exist in North America between some directly connecting lines of different ownership, but these are generally confined to cars in such traffic as that of coal, ore, etc., having a load in one direction only.

The revenue which the owner of the car receives from its user is somewhat increased by the collection of penalties charged for its misuse. For instance in North America in 1906, the per diem rate was 25 cents, but a penalty rate of an additional 75 cents per day was exacted if the car remained upon a road for more than thirty days, provided a notice that it was being unduly detained had been served on the holder of the car at the expiration of twenty days. The additional payments made under this plan amounted on the average to about 2 $^1/_2$ cents per day.

The penalty charges however are not made anywhere primarily for the purpose of increasing the revenue of the owner of the car. In some cases it is true they serve to reimburse the owner for the detention or misuse of the car, but in others they are designed by their severity to prevent the offence being committed. The charges exacted are from 25 cents to 5 dollars a day, the several rates not being imposed for the same reason, but for various offences against what is considered proper handling. These offences however, are of two general characters, — the failure to promptly return the car to its owner after unloading, and the misrouting of the car for the purpose of obtaining a load, in which traffic the owner of the car does not participate.

The return of a car empty over a different route from the one used on the outbound journey is sometimes penalized by requiring the erring road to pay to the road which hauls the car whatever the latter road must pay the owner of the vehicle for ordinary car hire plus an amount which varies from double to six times this car hire. The road which originates the diversion, or wrong sending, is responsible for the charges which accrue. The owner of the diverted car collects the charges from the user, but the latter inturn collects from the erring road, which is required to report its own delinquencies.

The custom of allotting a certain period of time for the journey of a car and charging a per diem or penalty rate for its detention beyond the limit allowed is in quite general use. Under the conditions which exist in North America however, an arrangement of this character is regarded as impracticable and it has never been attempted.

Generally, the penalty charge is fixed at a certain sum per day, but in other instances there is a heavy mileage charge added. The penalty rate is fixed in South Africa on the basis of so much per truck per hour and in East India at so much per ton per hour. The penalty rate for undue detention is very often, although not always, increased as time progresses. Instead of a penalty for bad conduct, a reward for good service is sometimes provided by an allowance of a certain free time, or of a reduced charge, for the return of a car within specified periods which

are graduated according to the length of the journey. This same method is also occasionally made use of to secure a return load, the per diem charge being cancelled when a car is returned loaded, but exacted if it is returned empty.

The penalty charges for diversion and wrong sending are often reckoned on a mileage and per diem basis for each car without regard to its size, but in some instances the penalty rate increases with the capacity so that while upon an ordinary car the rate is 75 cents a day, upon one of the heaviest tonnage capacity the rate is 5 dollars per day.

There is a penalty charge of one dollar on some roads payable to a car owner when the lading of the cars is transferred at the junction point in order to enable the receiving road to make better use of its own rolling stock. On the Italian roads, the penalty for breaking the established car service rules is a fine equal to ten times the ordinary mileage charge.

It is manifestly impossible to draw accurate conclusions as to the comparative economic efficiency of the freight cars of one or another country from an examination of the relation which the rate per day that is paid for their use in interchange car service bears to the cost of the cars, without taking other facts into consideration. The function of the freight car as a vehicle of transportation is to move a load from one point to another. For this movement, the owner of the load pays a certain sum, but this amount cannot all be credited to the car as its earnings, as is shown hereinafter. Yet there is a relation between the car and the freight earnings. For instance, if an isolated road has one million dollars of annual earnings from freight traffic and possesses one thousand cars, then each car earns on an average one thousand dollars per annum (1). Should one hundred of these cars be destroyed or be otherwise unavailable, the remaining nine hundred, with equal individual movement and the same freight rates, could earn only nine hundred thousand dollars and the business of the road would decrease one hundred thousand dollars. If, on the other hand, one hundred additional cars should be provided, without any increase in the volume of business passing over the line, then either these additional cars would be idle or the average earnings per car would be decreased and would be about 909 dollars per annum, or the quotient of 1 million dollars divided by eleven hundred.

The factors which affect the sources from which freight traffic is derived, are extremely various and often so remote that it is impossible for railway managers to anticipate with even approximate exactness what number of cars will be required for the business of the coming season. For instance in North America, the demand for cars was so greatly in excess of the supply in the summer of 1907 that about two hundred thousand new cars in addition to the two millions then on hand were ordered to be delivered in the latter part of the year. But certain influences had

(1) There were about 1,800,000 freight cars in actual service in the United States and the total earnings from traffic were reported as 1,823,651,998 dollars for the fiscal year ending 30 June 1907.

been for some time sapping the sources from which the business originated and suddenly in the latter part of November 1907 the effect of this culminated. There was a shortage reported of about ninety-one thousand cars on 1 November 1907. This shortage rapidly disappeared and ten weeks later, a surplus of three hundred thousand cars was reported, reaching a maximum of four hundred and thirteen thousand at the end of April 1908. So without the additional equipment provided in 1907, there would have been a surplus of from one hundred and fifty thousand to over two hundred and ten thousand cars, during a large part of 1908.

It cannot be assumed from these statements that the number of cars in actual service in North America was the difference between the figures given and the total equipment of 2,200,000, because of the large number of bad order cars on hand. In normal times, this number is about one hundred thousand, but it is certain that it exceeded two hundred thousand for a considerable part of 1908.

Doubtless similar variations in the demand for cars have everywhere been experienced, although perhaps not often so violent as in the case noted. But it may be deduced that the measure of the value of a freight car is not governed solely by the volume of the business, and that while this factor of the problem is important, there are other items which must also be considered.

In the case above cited, if the freight rates should be suddenly doubled without diminution of traffic the average earnings per car would be also doubled without any increase in the volume of business. The gross earnings of the car are therefore affected by the schedule of freight rates as well as by the volume of traffic.

If there are two connecting roads, one with high rates and a large traffic and the other with low rates and small traffic, the value of car as a revenue producer may be much more on the first road than the second road can afford to pay. Yet it may be possible that the stronger road could with advantage build additional cars for interchange with the other road if the latter could afford to pay enough for their use to cover the interest on their cost, plus an additional sum sufficient to cover maintenance and renewal, provided that cars were to be placed in traffic which would require them to be transported for part of their run over the tracks of their owner.

Cars so handled will not be as profitable to their owners as those which remain altogether upon their own lines, but will nevertheless yield some profit above the bare cost of of ownership. If, however, cars are engaged in any traffic in which their owners have no share a larger compensation may be justly demanded for their use from the administration in whose service they are engaged. Conditions vary so greatly in different countries and on different roads in the same country as to make it difficult to determine exactly what the possession of a freight car yields to its user. There are however to be found in the report of the United States Interstate Commerce Commission of the Statistics of Railways for the year ending 30 June 1907, som figures from which certain deductions may be drawn for that country.

The total capitalization of the railways of the United States on the above named date was 16,082,146,683 dollars. The earnings from freight traffic were about

seventy per cent of the total operating revenues and we may assume that seventy per cent of the total capital was that upon which the freight traffic was based. Those figures in round numbers are 11,256,000,000 dollars.

There were on the average about 1,800,000 freight cars in service in the United States during the year under consideration. Each car therefore represented 6,253 dollars capital investment for which it was the vehicle that earned whatever returns were secured. The average investment in a freight car in the United States was 722 dollars in 1907. This investment was incapable of producing any revenue without the aid of that part of the railway plant which is represented by the remaining portion (5,531 dollars) of the amount of capital investment allotted to the freight department.

The gross earnings from freight for the year were about one thousand dollars a car. The operating expenses were 67 per cent and the net revenue from each car figures therefore at 330 dollars for the year. Annual earnings of 330 dollars are equivalent to 90.4 cents per day, but no one would think of paying such an amount for car hire unless the conditions were very unusual.

These calculations are interesting, but as a matter of fact, such exact adjustments of rolling stock and other equipment do not exist in practice. The year ending June 30, 1907 was one of exceptional activity in business in the United States.

As a general rule, the arrangements between roads are reciprocal, that is, each pays the same per diem rate to the other for the use of its cars. In exceptional instances, however, when one road has a longer haul than the other a difference is made in the per diem charge to cover the expense of maintenance on account of the greater mileage run. Again in most cases the same per diem or mileage rate is in force throughout the year, but in one instance where the traffic is light for eight months and heavy for four months, the charge during the latter period is from four to five times as great as during the former.

Still another method is being experimented with, namely- an allowance of ten days free with a charge of 60 cents for the eleventh day and 1.35 dollars for each day thereafter.

In France, the fact that different conditions require different treatment is generally recognized and consequently each company makes with its neighbours such arrangements for the payment of car hire as may mutually be agreed upon, except that the State Railway pays and receives a mileage rate in all cases.

One problem to be determined is how much the owner of the car should receive from the user for its use, the question being complicated by the fact that when traffic is large the owner of the car loses heavily in freight earnings from its absence, while in times of light traffic he will often be glad to receive an amount barely covering the interest on the car and its upkeep, rather than to have it lying idle and deteriorating on a side track.

From the replies given, it appears that the capacity of freight cars varies from the little five ton van of England to the massive sixty ton car of Bavaria and North

America. Outside of North America there are very few cars of over 35 to 40 tons capacity. In North America there are not less than three hundred thousand cars having a capacity of fifty or more net tons.

A comparison of the cost of the various classes of freight cars is interesting. The lowest value given for any car is 310 dollars and the highest for an ordinary freight car 2,727 dollars. Values of special freight cars are reported as high as 5,655 dollars.

The figures are hardly comparable for any useful purpose as they depend upon cost of material, cost of labor, character of the structure and in some cases upon the charge for the transportation of the cars from their place of manufacture. All of these costs vary from one cause or another in the different countries and parts of the World. The values are stated in the currency of the country in the original responses.

The question of whether the best method of handling the interchange of freight cars either in the interest of efficient transportation, or for the protection of their owners, is by pooling the cars, or by compelling their proper handling and return by means of sharply enforced penalties for misuse, must be regarded as an open one.

The common use of cars without regard to ownership, appears primarily as if it would facilitate transportation, but without careful intelligent supervision and direction, cars may be found grouped in one section of the country when needed in a far distant section. The larger the number of cars and the wider the extent of the country, the greater will be the task of securing equitable distribution without excess empty mileage to restore the equilibrium. Yet it is certain that the movement of empty cars is increased by the enforcement of the prompt return of the cars to their owners by means of heavy penalties for diversion.

Perhaps the adoption of one or the other method depends upon the conditions which surround the traffic and these may differ in various countries or in different parts of the same country.

The ideal system would of course be one that would avoid all unnecessary empty mileage and have a sufficient supply of cars always on hand when needed for loading, but that would require the exercise of almost omniscience and omnipotence; omniscience because the unexpessed wants of the thousands of shippers for tomorrow and next day must be known, and omnipotence because the disobedience or disregard of orders may disarrange or destroy the proper working of the best devised plans.

The following general conclusion, however, appears to be based upon sound principles.

That when the nature of the traffic, the condition of the equipment and the relations between the administrations are such as to permit the pooling of freight cars, such practice presents advantages, provided the daily allotment of cars to the systems when they are needed is controlled by an impartial and efficient central office so organized as to be able to obtain sufficiently complete information as to the relative importance of demands for equipment, and to enforce its own orders. Each administration, party to the pool, should be entitled to have generally upon its line the

number of cars which it has contributed to the pool; but this provision should be disregarded when in the opinion of the central office the demand for cars elsewhere is more important in order to facilitate prompt movement. The distribution of the cars available on each system to the stations requiring them should be left in the hands of the local administrations.

Demurrage.

The difficult problem presented in North America with respect to uniform rules for the interchange use of freight cars between railway companies has been already mentioned. A still more difficult problem is presented with regard to the demurrage rules, for in addition to the vastness of the field to be covered there is added this further complication: There are 46 State Governments besides the General Government in the United States, and those of Canada and Mexico, and all of these forty nine powers claim the authority to intervene and to regulate the charges and provisions concerning demurrage by the passage of laws which according to the individual views of the legislators will prevent unjust discriminations or promote the interests of their citizens. Such political regulations are apt to be more or less affected by the opinions of those who are not wiser, but considered to be more numerous at the local polls. Besides this, the railway companies themselves are not entirely united in their views on the subject, partly owing to the different laws under which they must operate, but largely because of concessions that have been wrung from them in the past by shippers and consignees under the threat of the withdrawal of patronage in the face of severe competition. These concessions have become so ingrained in the methods of the railways, and of the business men of the different sections of the country, as to make an attempt to remedy all of the present evils a task of no small magnitude.

A further complication, which exists to some extent elsewhere arises from the fact that there are over 100,000 private freight cars in service on the North American railways, that is cars that are not owned by the railway companies, but by other corporations, (generally manufacturers), firms, or individuals. Many of the owners of these cars also own side tracks and in some cases, terminal roads of considerable extent. The status of these private cars when upon the tracks of their owners, or upon the tracks of other owners of private cars, has been a subject of much controversy. Some of these private cars are used not only in transporting the products of their owners but also to a considerable extent in general traffic.

The difficulty that is found everywhere, that freight cars are very variable units having numerous classes and kinds is also present.

In discussing the question of the interchange of freight cars, the value of the car to its owner and the result of its undue withdrawal from service by reason of delays caused by the action of the railways themselves was considered. Everything there said with regard to the damage suffered by the loss of the use of the cars

applies with equal force when there is unnecessary delay on the part of a shipper or a consignee. There are hundreds of thousands of shippers and consignees, and a very slight period of unnecessary detention of the cars on the part of a considerable number of these parties may be sufficient in the aggregate to seriously cripple the movment of the commerce of a continent.

Both shippers and consignees are entitled to sufficient time to load and unload their freight, but it is clearly in the interest of efficient transportation, that the time employed by the most active of them should be the measure to which all others should be required to conform, and that on behalf of the common weal, the slow moving, badly equipped, or idolent shipper, or consignee, should not be permitted to use any excess time beyond the minimum, or if he does he should be required to pay a compensating penalty.

The following summary of the prominent features of the demurrage regulations is for countries other than North America.

The units upon which the demurrage charges are generally based are, as in the case of the charges for car hire, the day of twenty-four hours, and the car, without regard to its loading capacity. Yet there are several sliding scales of prices. The rates of increase in these scales are sometimes based upon time, as for instance where the rate is 50 cents for the first day detention, while it is 1 dollar on and after the third day. In other cases the rate of charge is increased with the capacity of the car, so that for 1 of 12 tons capacity the rate is 1·60 dollar per day, while for a 25 tons car the rate is 3 dollars and 20 cents a day.

Tank cars are generally considered as in a class by themselves and subject to a special rate of demurrage. All classes of cars is most countries are subject to demurrage charges. In some cases when no demurrage is charged for the car itself, a charge is made for the occupancy of the track. Exception is sometimes made in favour of private cars on private tracks, and in others on private cars when on the tracks of their owners only. Charges for detention of cars containing perishable lading are included sometimes under the head of demurrage.

The free time allowed before the demurrage charge begins to accrue is generally from twelve to twenty-four hours, but this may be shortened in case of the accumulation of freight, sometimes as much as one third. In other cases, but eight working hours are allowed with two hours extra where customs examinations are made. Sometimes all the working hours of the day following the receipt of the notice to the consignee of the arrival of the shipment are free. Again, cars placed before 9 a. m., must be unloaded the same day and if placed after that hour they must be unloaded before 12 o'clock the following day. In England, the free time must be " clear days ".

Occasionally the capacity of the car is considered, as in Russia where six hours for loading and twelve hours for unloading is allowed on small cars and double this time on large cars.

In South Africa, twenty-four hours are allowed for unloading and twelve for load-

ing. Tank cars are in some cases allowed three days and coal and coke cars thirty-six hours.

On Sundays and Holidays throughout the World, no demurrage charges accrue.

The distance the consignee lives from a station is sometimes taken into account and an additional allowance of time made for it, but generally this is not considered as the consignee is supposed to know that a shipment for him is about to arrive and it is expected that he will be prepared to receive it.

The principle which governs the method of computing the free time allowed before the demurrage charges accrue is based upon the idea that the consignor or consignee has the car in his possession as soon as it has been placed for loading or unloading on a public track, and that the time granted is sufficient for the required work. Delays caused by custom house or excise regulations are allowed for when the detention is not caused by the fault of the shipper or consignee. When the time is restricted to less than a full day the free time is reckoned from some specified and designated hour.

The time of the delivery of a notice to the consignee is reckoned from the hour when the car is actually or constructively placed in his possession. If the notice is sent by mail, a certain time is allowed for its delivery, sometimes not over three hours. The placarding at a designated place in the station of the notice of the arrival of a shipment, is in some cases considered sufficient notice to the consignee. Detentions plainly caused by tempests, floods or other acts of Providence, are not counted in reckoning the demurrage charges.

The hour of placing a car on a private side track is taken as the commencement of the free time, and a shorter time is generally allowed than in the case of a public siding.

Special notice in advance that demurrage will accrue after a certain hour is not generally considered necessary, but it is quite customary to send such notices as a matter of convenience, and to facilitate the work of unloading, even when not required.

Notifications when required may be sent by messenger, telephone, telegraph message or by mail; in the latter case on printed forms. The notices give information as to the time of the arrival of the consignment, and are sometimes, but not generally supplemented by a second notice as above mentioned. The rules as to the demurrage charges are frequently printed on the form of the notice. The non-receipt of the notice is not accepted as an excuse in India and in Russia. In Australia and some parts of Europe, notices are not required. Sometimes the only notice give is in the form of a statement on the bill of lading.

In England, the fact is made prominent that cars detained for goods to be unloaded are held by the companies as in warehouses and not as carriers.

A deposit is sometimes demanded, to cover possible demurrage chorges, at the time a car is placed for loading or unloading. If a car is ordered and not used the deposit is forfeited to the railway company.

When a car is promised to a shipper, a penalty may be collected by him if the car is not furnished. But where such regulations exist, no promise is permitted to

be made to a shipper unless the car ordered is actually at the station. Where a promise is made in advance it may be cancelled without penalty upon notice to the shipper given a certain prescribed time before the hour the car was to be placed.

Requests from shippers for cars are considered as information and are accepted only within the capacity of the service.

The delivery of cars ordered to be placed on private sidings is generally governed by special contract.

The ordinary places for loading and unloading are supposed to known to both shippers and consignees.

The inability of consignees to receive freight does not exempt them from demurrage and cars may be unloaded and the goods stored at the cost of shippers or consignees.

The refunding of demurrage collected is not generally favored and where allowed the amount of such restitution is not more than half the sum remaining after deducting the expenses which the railway has incurred on account of the detention of the car. Applications for this restitution are treated on their merits and granted only in exceptionably favorable cases, when the railroad was at fault or when from natural causes (floods, snow-drifts, etc.), unloading was impossible or dangerous, or the freight might have been damaged if moved. All applications for refunding demurrage are refused in times of car shortage.

It should not be understood that all of the demurrage regulations above noted are to be found in the replies of any single administration. Yet it must be conceded that they all possess merit and are calculated to facilitate promptness and efficiency in transportation. Where any of them cannot be enforced, it is not because they ought not to be, but on account of some reason of a commercial nature. These reasons are occasionally sound, but often are merely urged in the selfish interest of a particular customer, or class of customers, by whom concessions are sought which can only be granted at the expense of the rest of the commercial world.

The Demurrage Rules of the American Railway Association, which are used in North America, are given in full in the appendix to this report. They are recommendatory in their character.

The following principles, which should govern the formulation of demurrage rules, are presented as the conclusions of this part of the report :

1° The prompt release of loaded cars and the prompt loading of empty cars are essential to the efficient operation of railways in the interest of both shippers and carriers;

2° The undue detention of cars by consignors or consignees prevents the distribution of empty cars to other patrons and causes car shortages in times when business is prosperous;

3° The service to be rendered by the carriers in consideration of the freight charges does not include the use of the cars for storage purposes by the consignee;

4° The occupancy of cars by consignors or consignees is of value to them and a cause of expense to the railroads;

5° The only method of preventing the undue detention of cars by consignors or consignees is by the imposition of charges for their occupancy and that of the tracks upon which they stand, and these charges are fully justified by the conditions as stated above in 1°, 2°, 3° and 4°;

6° The free time allowed for loading and unloading should not be greater than the time necessary for those purposes when adequate facilities are employed and due diligence exercised by the consignor or consignee;

7° The amount of the demurrage charge should be larger than the storage charge for the use of a warehouse for the same period.

The following table shows the amount charged for Care Hire for cars of various costs, their average loading capacity, the free time allowed for loading and unloading and the Demurrage charges. In translating the mileage rates into per diem rates it was necessary to assume an average daily movement and this, when not specified in the regulations, was taken as 25 miles (40 kilometres) that having been found by the statistics of the Committee on Car Service of the American Railway Association to be about the average in that country (1). Thus a rate of one and a quarter centimes per kilometre makes fifty centimes (10 cents) per day which added to the per diem rate of 25 cents makes a total " car hire " of 35 cents per day.

Summary statement of charges for car hire and demurrage.

Car hire rate per day U. S. currency.	Cost of cars (1).	Loading capacity metric tons.	Free time allowed for		Demurrage charges per day U. S. currency.
			loading hours.	unloading hours.	
15 cents.	750 to 980 dollars.	10 to 11	24	24	2 to 2·40 dollars.
22 1/2 —	325 to 925 —	12 to 16	24	24 to 36	24 cents to 1.15 dollars.
25 —	466 to 1,069 —	18 to 45	48	48	1 dollar.
25 to 60 —	870 to 1,450 —	...	24	24 to 36	24 cents to 1 dollar.
28 —	435 to 700 —	11 to 14	8	8	1·20 dollars.
35 —	650 to 1,100 —	5 to 25	12 to 24	12 to 24	50 cents to 1 dollar.
37 1/2 —	310 to 2,550 —	9 to 37	24 to 48	48	(2)
45 —	723	13	24 to 48	24 to 48	60 cents to 1 dollar.
30 to 60 —	325 to 1,060 —	5 to 40	48	48	75 cents to 5 dollars.
65 —	400 to 900 —	13 to 35	24	24	1 cent per ton.

(1) These prices are for cars in general service. There are also special cars which vary in cost from 975 to 5,655 dollars for which the ordinary rates of car hire and demurrage apply unless otherwise noted in the detailed responses.

(2) 25 cents for each 1,000 kilograms of maximum load of car.

(1) This daily movement of 25 miles is the average for all cars in service. On the other hand, a freight car which starts from New York is delivered at Chicago in from three to five days, the distance being from 908 to 1,047 miles according to the route taken.

For comparisons as to relative efficiency these figures are not exact, but for the purpose for which this report is compiled they are at least interesting without further refinements. For those refinements a knowledge of the comparative freight rates and of the volume of traffic would be necessary. That would involve an almost impossible compilation and then would be practicably incapable of statement in a concrete form. It is evident however, that other factors besides the cost of the car and its tonnage capacity have affected the car hire and demurrage rates.

All the railways of Continental Europe, except Russia, are also in the International Car Service Agreement which covers all cars not included in special agreements. In this agreement the Car Hire rate is 8 tenths of a cent per mile *plus 50 cents a day*, for cars over 15 tons capacity.

The following table giving the relative values of the various monies, weights and distances named in the responses will be found convenient for reference. While fractional values are omitted the figures are sufficiently accurate for comparison and adapted for ready calculation.

Monies.

—	American value.	English value.	Latin union value.	German value.

Nota. — The replies of the Administrations are published in the appendices of this report; they will be found in the *Bulletin of the Railway Congress* for January 1910, p. 28.

SECTIONAL DISCUSSION

Meeting held on 11 July 1910 (afternoon).

MR. DIETLER, PRESIDENT, IN THE CHAIR.

The President. (In French.) — I call upon Mr. Allen to address the meeting.

Mr. W. F. Allen, *reporter.* — The Permanent Commission was good enough to accord me the privilege of obtaining through the organization of the Congress, certain information respecting the interchange use of freight cars and the means taken to prevent their unnecessary detention by shippers and consignees, for the especial use of our American railways. The information requested was very kindly supplied by the administrations who were asked to do so, and it has been presented in the form of a " Note " to the present Congress.

From the nature of the replies received, it is evident that the problems which these two cognate subjects present, are of a similar character everywhere throughout the world, and that an entirely satisfactory solution of them has not as yet been developed anywhere.

Every management desires to make the best possible use of freight cars and to be able to command the services of its own cars whenever they are required. Each desires also to limit the haulage of empty cars as much as possible. The demands of trade appear sometimes to be antagonistic to these desired ends.

Interesting experiments are now being made in this branch of railway operation in various parts of the world, as for instance the " pooling " of all freight cars belonging to the administrations within the limits of the Empire of Germany.

While much valuable information was obtained for the " Note " which I have had the honour as a reporter to present, yet I am very conscious of the fact that the subject is by no means exhausted, if the best results of the investigation of the question are to be secured.

I would therefore move the adoption of the resolution presented, believing that the request therein contained will be favoured by operating railway officials in many of the countries represented in the Congress.

" The members of the third section who are especially interested in the operating of railways, respectfully request that the Permanent Commission will consider the utility of investigating the question of

freight-car interchange and demurrage, with the view of including it among the list of subjects to be discussed at the ninth session of the International Railway Congress."

Mr. Patterson, Pennsylvania Railroad. — On behalf of Pennsylvania Railway interests of U. S. A., I desire respectfully to add my word in favour of what my confrere Mr. Allen has said, more particularly as to interchange of equipment between Railways.

The road which I have the honour to represent is one of the largest owners of equipment in the world, and neither internally as between the different shades of opinion amongst our own officers, nor externally as regards our relations to other railroads have we reached any general universal principle on which to work.

When we turn to our friends in the old world for aid, the same failure to accentuate a definite general principle confronts us.

In some cases, they as well as ourselves accentuate the rights of the owners of equipment to receive back their cars on demand. On others, they accentuate the waste of mileage in any such course and its economic features from the standpoint of the shipper, and as intimated by Mr. Allen, it seems a world-wide problem well worthy of the consideration of this honourable body.

Mr. Hale, American Railway Association. — In seconding the resolution, I beg to say that the question is especially interesting in America, where the freight-car question is still an open one, and where the rates of payment for freight-cars have been changed even since Mr. Allen's note was presented. It has been said that the American situation is in fact a pool without regulation. This cannot continue indefinitely and the Americans are anxious in handling the question to profit by the experience of the railways in other countries, especially in Russia, India and Germany, where progress has been made in the regulation of freight-car pools. I feel also that this is a subject of special interest in these countries.

They have found that the periods when their cars have been on the whole most efficient were periods when the interchange has been the greatest, and that most present arrangements do not recognize this fact.

Mr. Lüttke, Prussian State Railway. (In German.) — Allow me to say a few words. It is within my knowledge that all the German railways belonging to the railway wagon union of the German States are perfectly satisfied with the existing state of affairs, as regards the question which we are considering at this moment. This union has regulations which approximately satisfy the object which Mr. Allen is aiming at in the case of the American railways. We, moreover, have fairly suitable conventions about the reciprocal use of wagons within the limits of all the countries concerned.

Nevertheless I am convinced that it would be very useful to continue the study of this subject and that, from this point of view, progress could be made by which the railways would benefit; not only the American railways, but also the other railways, perhaps also, last but not least, the German railways.

I hence strongly support Mr. Allen's motion.

Mr. Kareischa, *principal secretary*. (In French.) — The Russian railways have succeeded in coming to an agreement about the question of the interchange of rolling stock. The results obtained are favourable, but nevertheless I strongly support Mr. Allen's motion.

The President. (In French.) — I note that all the speakers support Mr. Allen's motion.

I accordingly declare it adopted.

DISCUSSION AT THE GENERAL MEETING

Meeting held on 16 July, 1910 (morning).

MR. P. WEISSENBACH, PRESIDENT, IN THE CHAIR.

GENERAL SECRETARY : MR. L. WEISSENBRUCH.

FIRST ASSISTANT GENERAL SECRETARY : MR. MÜRSET.

SECOND ASSISTANT GENERAL SECRETARY : DR. A. BONZON.

Mr. Kareischa, *principal secretary of the 3rd section*, read the

Report of the 3rd section.

(See *Journal de la huitième session*, No. 9, p. 15.)

" Mr. ALLEN brought forward his resolution and thanked the Permanent Commission for having allowed him to ask for information from the administrations, respecting the interchange use of rolling stock.

" From the replies kindly sent, it followed that this problem had not yet been solved satisfactorily. Every railway management desired to regularize the use of the rolling stock, and to make the best possible use of it. Interesting experiments were being made, more especially by combinations between railways, and the international study of this question would be of much interest.

" Mr. PATTERSON (*Pennsylvania Railroad*) seconded Mr. Allen's resolution; as his company was one of the largest owners of equipment, it would highly appreciate a good solution. The same difficulties appeared to turn up in other countries besides America. The owners of equipment accentuated their rights to receive it back as soon as possible. Shippers were as interested in the problem as the companies.

" Mr. HALE (*American Railway Association*) stated that the question was unsolved in America and that it would be desirable to regulate matters. In Germany, good results had been obtained. The best utilization had been when interchange had been greatest. It was desirable to know the experience of other countries, especially Germany, Russia and India.

" Mr. LÜTTKE (*Prussian State Railway*) stated that the German administrations were satisfied with the system adopted by

the union for the interchange of rolling stock. This question was important and its investigation should be continued.

" Mr. Kareischa (*Russian government*) mentioned that the Russian railways had arrived at an agreement on the subject of the interchange of rolling stock, and that it was desirable that uniform and general regulations should be adopted.

" The President noted that all the speakers had supported the proposal made by Mr. Allen; the 3rd section would submit this resolution to the Permanent Commission, so that it might be included in the agenda for the next session."

The President. — The following is the

RESOLUTION.

" The members of the eighth session, " who are especially interested in the " operating of railways, respectfully re- " quest that the Permanent Commission " will consider the utility of investigating " the question of freight-car interchange " and demurrage, with the view of includ- " ing it among the list of subjects to be " discussed at the ninth session of the " International Railway Congress."

— The general meeting confirmed this resolution.

II — MISCELLANEOUS MATTERS

1. — Letter from the Spanish ambassador at Berne.

At the general meeting of 14 July 1910, Mr. Weissenbach, President, read the following letter which had been sent to him by His Excellency Count de Chacon, the Spanish ambassador at Berne :

" Mr. President,

" I am directed to transmit to Your Excellency the greetings of His Majesty Don Alphonso XIII, with the request that you will have the kindness to inform the meeting of the interest which His Majesty feels in its work, which cannot fail to be productive for science and to form a new means for drawing the bonds of union between the different countries more closely together.

" I have the honour to be,

" Mr. President,

" Your obedient servant."

(*Signed*) Count de Chacon.

The meeting charged the President to request the Spanish ambassador to express to His Majesty King Alphonso XIII, the gratitude of the Congress Association for the interest His Majesty had condescended to take in its work, and to inform him that this Association especially appreciated the wish he had expressed of seeing the bonds uniting the different countries thus drawn more closely together.

* * *

2. — Telegram from the President of the United States.

Mr. W. H. Taft, the President of the United States, sent to Mr. Franklin Lane, the chief delegate of the United States government, the following telegram :

" I send greetings to whole International Railway Congress and sincerely hope that their conferences will result in general benefit and improvement of railway methods."

William H. Taft.

In reply to this telegram, Mr. Weissenbach, president of the session, sent the following letter to the United States ambassador at Berne :

" Sir,

" The International Railway Congress Association fully appreciates the expression of goodwill which the President of the United States, Mr. Taft, was kind enough to send by wire on the occasion of the official banquet of 14 July 1910.

" The Congress has charged me to request you to transmit to the President its gratitude for the interest he kindly showed in its work.

" I have the honour to be,

" Sir,

" Your obedient servant,"

(*Signed*) Weissenbach,

President of the eighth session of the International Railway Congress Association.

* * *

3. — Communication by Mr. P. de Tchérémissinoff.

Mr. P. de Tchérémissinoff, privy councillor, manager of the international services of the Russian railways and member of the Permanent Commission, reminded the Congress of the great interest with which it had listened, during the inaugural meeting of the eighth session, to the figures relating to the development of the Federal Railway in Switzerland.

This suggested to the Russian delegates the idea of presenting to the Congress a similar memoir relating to the railways in their country. Mr. de Tchérémissinoff laid on the table an abstract he had prepared of the great work of Mr. N. de Petroff, engineer general, head of the Russian delegates at the present Congress and president of a high commission of investigation of the railways in Russia. (*See addenda to various motions.*)

* * *

4. — Documents laid on the table.

a) *By the Mexican railways :*

Messrs. Rafael Garcia y Sanchez Facio and Estanislao Velasco, delegates of the Mexican government, presented the Congress with an account of the railways of the United States of Mexico, compiled for the eighth session by order of the President, General Diaz, and of the present secretary of communications, Mr. Leandro Fernandez. This interesting work contains a complete summary of railway affairs of this great Central American republic up to 31 December 1909.

b) *By the local committee organizing the eighth session :*

The local Swiss Committee, on the other hand, presented the delegates with the new federal law, of 23 June 1910, concerning the pay of the officials and the employees of the Swiss Federal Railway (referendum time expiring 4 October 1910).

— Copies of these documents have been placed in the library of the Permanent Commission.

ADDENDA TO VARIOUS MOTIONS

NOTE

ON THE

DEVELOPMENT OF THE RUSSIAN RAILWAYS,

By Pierre de TCHÉRÉMISSINOFF,

PRIVY COUNCILLOR,

MANAGER OF THE INTERNATIONAL SERVICES OF THE RUSSIAN RAILWAYS.

By 1904, the time when the Russo-Japanese war started, the amount expended by the Treasury on the construction of railways amounted to 11,500 millions of francs (£460 millions), and the national debt at that time amounted to 16,500 millions of francs (£660 millions).

A considerable part of the capital expended, namely nearly 3 milliards of francs (£120 millions), had however been supplied from the budgets of the financial years 1888 to 1904, thanks to the exceptionally favourable results of those years. On the other hand, the sums raised by loans had to cover the guaranteed payments, amounting to hundreds of millions, during the periods preceding the buying up of the different railway lines by the State.

At first the railways proved very expensive, although necessary for the gradual development of the State; but in 1898 they had yielded enough to pay 4·5 per cent on the capital expended by the treasury, plus a profit of about 60 millions of francs (£2·4 millions) to the State.

New main railroads were then built. Then came the war and internal troubles, and these resulted in a material increase in the working expenses.

Between 1888 and 1903, the total length of the Russian railway lines has approximately doubled, increasing by about 32,500 kilometres (20,200 miles); of these 24,000 kilometres (14,920 miles) are in Russia in Europe and 8,500 kilometres (5,280 miles) in Siberia.

The traffic grew, even in 1906, at a quicker rate than the railway system. The passenger traffic increased in the ratio of 1 to 2·13, the quick-freight traffic in that of 1 to 10, and the slow-freight traffic in that of 1 to 2·92.

The mean mileage, for the 93 millions of passengers, was 100 kilometres (62 miles), and for the goods, 450 kilometres (280 miles). The value of the goods carried in 1906 was nearly 8 milliards of francs (£320 millions), which as compared with 1888, represents an increase of 5 milliards of francs (£200 millions). The growth in the cereals traffic, representing a weight

of 40 million tons, corresponds to the increase in the area under cultivation. The vegetables, which could not be carried by river, had a total value of 800 million francs (£32 millions) (at 30 centimes per kilogram [1·31*d.* per lb.]). The sale of the goods carried, which produced about 3 milliards of francs (£120 millions), enabled the people to pay to the railways the sum of 375 millions of francs (£15 millions), the greater part of which was returned to them in the shape of salaries and of payments for materials consumed. The taxes could be raised materially. The mean tax paid per inhabitant had been 17·80 francs (14*s.* 3*d.*) in 1888; it had increased to 42·50 francs (£1.14*s.*) in 1906. Moreover, the ordinary receipts which amounted to 2·25 milliards of francs (£90 millions) in 1888 rose in 1906 to 5 milliards of francs (£200 millions).

The railways beyond the Ural Mountains have also materially benefited the State and the people, although the treasury had to spend an annual sum of 150 millions of francs (£6 millions) to pay the interest on the capital outlay and to cover the working deficits of some of the lines. This expenditure has above all helped towards the better defence of the frontier; the Southern line runs along more than 9,000 kilometres (5,600 miles) of this frontier.

The Siberian lines have, moreover, enabled a certain part of the population of Russia in Europe to emigrate in order to take possession of the vast fertile lands in Siberia and in the countries to the east of the Caspian Sea. This emigration was organized and assisted by the State. Every year five to seven hundred thousand men leave their homes in Russia in Europe in order to go east. The million hectares (2,471,150 acres) of land which hardly sufficed for them and which they leave to those who remain behind, represent a value of approximately a quarter milliard of francs (£10 millions); while they readily find in Asia the two million hectares (4,952,300 acres) which they require in order to give their energies full scope.

In this way, 400,000 families emigrated between 1901 and 1909, say 2 million people, and thus about 4 million hectares (9,884,600 acres) more land became available for the population of Russia in Europe.

The immigrants in Siberia receive, on the average, 7·3 hectares (18 acres) of arable land per family, yielding them a gross revenue of 125 francs per hectare (£2.0*s.* 5·6*d.* per acre). The total amount of these revenues in Siberia amounts to 375 millions of francs (£15 millions). The export of Siberian butter by itself produces a gross revenue of 125 million francs (£5 millions). The growth of cotton in the Transcaspian countries has reduced the imports of that article into Russia by about 250 millions of francs (£10 millions).

The legislature of the country has just granted large sums for duplicating the main Siberian line and the Transbaikal line, and for building a new line along the north bank of the Amur.

This great further expenditure will help to secure the safety of the frontier and will also help to develop the vast districts through which those lines will run.

CLOSING CEREMONY

On Saturday, 16 July 1910, at 10 a. m., the delegates assembled in the hall where general meetings were held. Mr. WEISSENBACH took the chair; Mr. DUBOIS, president of the Permanent Commission of the Congress, was on his right, and Mr. L. WEISSENBRUCH, general secretary, was on his left.

The meeting first dealt with the different sectional reports.

. . . . . .

THE GENERAL SECRETARY then read, in the name of the Permanent Commission, the following proposals which were passed :

A. — **Membership.**

" 1° That the appointment of the following members elected in the interval between the two sessions be approved :

" 1, BAÏDAK; 2, BIANCHI; 3, CECIL; 4, Lord CHURCHILL; 5, DETHIEU; 6, ELSNER; 7, FRANKE; 8, GLEICHMANN; 9, Fairfax HARRISON; 10, PHILIPPE; 11, H. Llewellyn SMITH; 12, STEINBISS; 13, TONDELIER.

" 2° That the following members be reelected :

" 1, RAMAECKERS; 2, BEAUGEY; 3, COLSON; 4, DE RUDDER; 5, DUTREUX; 6, GUERREIRO; 7, Frederic HARRISON; 8, OAKLEY; 9, ROUSSEAU; 10, SARRE; 11, STEVENS; 12, ULBRICHT; 13, WEISS; 14, DE WERKHOVSKOY; 15, VON ZLUHAN; 16, WEISSENBRUCH.

" 3° That in place of Messrs. JEITTELES and MASSA, deceased, and of Messrs. VON BILINSKI and NOBLEMAIRE, who are retiring, the following should be appointed members of the Permanent Commission : Dr. RÖLL, chief of section at the Imperial Royal Railway Ministry of Austria, vice-president of the session; Mr. GERSTNER, State councillor, representative of the directors of the Imperial Royal directorate of the lines of the Austrian State Railway Company, president of the 2nd section; Mr. CAJO, assistant general manager of the Italian State Railway; and Mr. MAURIS, director of the Paris-Lyons-Mediterranean Railway Company.

" 4° Messrs. ELLIOTT and KRUTTSCHNITT, whose appointments have expired and who do not wish their appointments to be renewed, are, by agreement with the American members present at the session, replaced by Mr. F. K. LANE, Commissioner of the Interstate Commerce Commission and vice-president of the eighth session, and Mr. W. F. ALLEN, general secretary and treasurer of the American Railway Association.

" 5° The Permanent Commission is charged to provide for the vacancy caused

through the recent death of Mr. Adadouroff, and of Messrs. Dietler, von Leber and de Marez-Oyens, who came under the operation of article 7 of the constitution.

" 6° As it is a regular practice to increase the number of places reserved in the Commission for the country which has received the Congress, the number of members for Switzerland is to be increased by two. The two new places are to be given to Mr. Winkler, technical manager of the Federal Railway Department, and to Mr. Flury, vice-president of the general management of the Federal Railway. " (*Applause.*)

" 7° Mr. Weissenbach, in his capacity of president of the eighth session, is appointed life-member of the Commission.

" In order to give the Scandinavian countries the place which formerly belonged to them, the vacancy to be filled is to be given to Mr. Ambt, general manager of the Danish State Railway."

The President laid the accounts on the table. Messrs. Carlier (*France*) and de Tchérémissinoff (*Russia*) were appointed auditors to check the accounts in accordance with article 19 of the constitution.

B. — Selection of meeting-place for next session.

The General Secretary. — " The Permanent Commission has considered suggestions respecting the choice of place for the next session.

" Germany has been proposed. No other proposals have been made. At the suggestion of Mr. Weissenbach, the president, the Permanent Commission proposes to you that the ninth session shall take place in Germany.

" The German delegates, on the proposal of Mr. Weissenbach, gave the Commission every assurance that the German government would be very happy to see the Association meet at Berlin and promised it an excellent reception." (*Applause.*)

The President. — " This acquiescence of Germany will certainly be received with gratitude on all sides. I hope that the Congress will accept with alacrity the proposal which has been made." (*Applause.*)

— " The proposition was accordingly passed."

Mr. Petri, vice-president. — " I thank you, gentlemen, in the name of the German delegates, for the flattering readiness with which you have accepted the invitation of Germany to hold the next session of the Congress at Berlin.

" The German empire, its capital Berlin and the administrations of the German railways have the greatest desire to give you a friendly reception and will make every effort that the Berlin session may prove worthy of the preceding ones.

" Returned to our homes, we, the German delegates, will tell everybody of the success of the eighth session of the Congress. We shall retain an ineffaceable remembrance of the laborious and agreeable days of this session as well as of the pleasant intercourse we have had with our colleagues from other countries.

" May our colleagues also retain as pleasing a recollection of us until the moment five years hence, when we shall have the great honour of calling you our guests and of bidding you welcome in Berlin, the German Imperial city.

" It is with this happy hope that we say to you: *au revoir in 1915 !* " (*Applause.*)

Mr. Weissenbach, president. — " Gentlemen, the eighth session of the International Railway Congress has closed its labours, and I have the great satisfaction of noting that the results of this meeting worthily add to the successes which have during twenty-five years marked the activity of the International Association.

" The first thought which a glance at these results inspires in us, is that of gratitude to the Permanent Commission at Brussels, which during five years has with untiring industry prepared the questions to be brought before the Congress. In the first place I must mention Mr. A. Dubois, who presides over it and has acquired the profound esteem and liking of all of us. Our gratitude is equally due to our general secretary, Mr. Weissenbruch, who has worked with remarkable activity and untiring zeal at the proper execution of the programme of the Congress. It is above all to his indefatigable industry that we owe it that we were able to carry out our work in so well-arranged and so regular a way.

" Our thanks are also due to the treasurer of the Congress, Mr. Holemans, for his indefatigable activity, to Mr. Verdeyen, the assistant-secretary, to the staff of the secretariat, and especially to the head of its office, Mr. Habran.

" We must also not forget the publication of the daily *Journal de la huitième session;* this work was carried out in a perfect manner under the direction of the Permanent Commission and of Mr. Mürset, the general secretary of the Federal Railway.

" The gratitude not only of the Congress, but of the whole railway world, is equally due to the eminent specialists whose reports, carefully elaborated, have enabled us to discuss thoroughly the most important questions relating to railways.

" We also thank the presidents and vice-presidents of the sections for the trouble they have taken and the work they have done, as well as their secretaries and all the staff of the different sections which has so actively seconded their efforts. It is due to their ability that the sectional discussions, although conducted in three languages, could be so thorough and so effective. I must specially mention the active share taken in the discussion of the most important questions by the English-speaking delegates who have come to us from all parts of the world.

" In conclusion, I still have to express the great satisfaction felt by the Congress in the interest shown in it by the Federal Council of the Swiss Federation, by charging Dr. Forrer, Federal Councillor, head of the Railway Department, with the formal opening of the Congress, and Mr. Comtesse, president of the Federation, with greeting us in its name. We especially thank Dr. Forrer, Federal Councillor, for having accepted the position of honorary president of the session.

" The work of the eighth session is finished, but that of our Association will continue without break, with the same indefatigable ardour, under the skilful direction of the Permanent Commission which is located in Brussels; and we are all quite convinced that the activity of the Congress will continue in the future to give excellent results for the development and the prosperity of the railways of the whole world." (*Applause.*)

Mr. Dubois, president of the Permanent Commission. — " Gentlemen, my first duty is to thank Mr. Weissenbach, who kindly consented to preside over the work of the eighth session and has done so with an ability, a zeal and an urbanity which you have been able to value. In my speech of 4 July, I recalled the eminent men whom we have had the good fortune to have as presidents at the first seven sessions; to that list of honour we add today the name of our president Mr. Weissenbach.

" In his speech, he gave words of praise to the Permanent Commission, to its president, its general secretary, and to Messrs. Holemans, Verdeyen and Habran. That praise is too flattering as far as I am concerned, but I accept it with great pleasure as regards my collaborators and especially Mr. Weissenbruch; better than anyone else have I long since been able to appreciate his qualities of intellect, of devotion to work and of moral energy.

" At the great banquet of 14 July, I was called upon to thank in your name the Federal government, which has treated us so generously and at the same time so cordially. You will recollect that entertainment, at which the President of the Federation magnified, in eloquent language, the functions of our Association, praised its past work and encouraged its future efforts. You will not forget that ingenious supplement to the banquet, that very cleverly-organized entertainment, which during two hours showed us all the scenes of Alpine life.

" We have also incurred a debt of gratitude towards the city of Berne. The municipal council invited us to a friendly meeting early on our opening day. We had hardly arrived and already we were at home, and that in a pleasant hospitable and comfortable home. We shall retain pleasing recollections of our stay in this charming city of Berne, admirably situated, surrounded with enchanting vistas, rich in glorious memories, which side by side with old picturesque buildings, carefully preserved, also offers us beautiful new buildings, many of which are veritable palaces.

" In my speech of the 4th instant I already mentioned the valuable assistance given by the provisional Swiss section to the Permanent Commission.

" Today, when the most complete success has crowned its efforts, I again wish to thank it, as represented by its president, Mr. Weissenbach and its secretaries, Messrs. Mürset and Bonzon. In truth, if any grumblers (and there are some in the Congress as elsewhere) want to raise some criticism against the superb programme elaborated by the Swiss section, the only one which they can find is that it gave no end of perplexity to those who had to make their choice among the excursions, all rivalling each other in interest, in usefulness and in pleasure.

" I also thank the chief committee of the Swiss section; the executive committee, presided over by Mr. Winkler, the secretarial committee, presided over by Mr. Mürset, having Messrs. Elskes and Étienne as chief collaborators; the local committees organized for Berne, Lausanne-Montreux, the Oberland, Lucerne and Zurich; and the Swiss secretary-reporters.

" I thank the public authorities, the administrations of the railways, tramway and navigation enterprises, the companies, and the private individuals who have

worked with goodwill, zeal and generosity in order to co-operate in the brilliant success which we can delight in today.

" Finally I thank the Swiss population which we have seen, so pleasant, so cordial, so ready to render services, and which we shall all leave with sorrow." (*Prolonged applause.*)

Mr. DE PÉTROFF, engineer general, member of the Imperial council of Russia, member of the Permanent Commission of the Congress and vice-president of the session. — " Gentlemen, allow me to address some words to you in the name both of my Russian compatriots and of myself. It is with the greatest interest that we have followed the development of the work of the Congress, which has attracted from all parts of the world a brilliant assembly of so many men of science, of talent and of great experience, able and competent to indicate here the quickest and safest means for solving questions of all kinds concerning railways.

" The work of the Congress was of quite special interest to the Russian representatives. Like everybody else in this world, we are convinced that there are imperishable ideals.

" Thanks to one of these ideas dating back to remote antiquity, the European people do not forget the wish of creating a convenient means of communication with the East Indies, with that cradle of the world where nature has accumulated inexhaustible riches and where we find again all the poetic and religious traditions of ancient and of modern nations.

" The first attempt of European people to make a way to India dates back to the celebrated expedition of the greatest general of antiquity, to Alexander of Macedonia, but the enterprise of this illustrious conqueror stopped when he had arrived on the banks of the Ganges.

" At the present time, thanks to the enormous progress of navigation and especially to the construction of the Suez canal, only one last step remains to be made.

" We hope and are convinced that the peaceful ideas and the sentiments of civilized people, and not universal warefare, will indicate to us the best means and those most suited to our times to realize the dream of antiquity.

" We shall develop there means by our activity in the construction of railways.

" Once we have grasped this and recognized its justice, we shall soon see, if we cast a glance at a map, that the shortest way from eastern Asia to western Europe is across the Russian territories in Asia and in Europe.

" Let us hope that the construction of these ways connecting eastern Asia and western Europe will not be long before it is realized. We are doing our best to construct and organize our railways in the way best suited to modern requirements, in accordance with the views of the Congress, so that our railways may form a suitable and convenient means of communication both for passengers and for the carriage of goods. It is for this reason that we have followed, with the greatest interest, the work of this Congress and that we wish the greatest success to future Congresses." (*Applause.*)

THE PRESIDENT then declared the eighth session closed.

PERMANENT COMMISSION

AND

EXECUTIVE COMMITTEE

elected at the General Meeting of the Congress on 16 July, 1910, and at the Meeting held by the Permanent Commission on the same date (arts. 5, 6 and 7 of the statutes).

Permanent Commission.

President :

A. **Dubois** (1), ingénieur, administrateur honoraire des chemins de fer de l'État belge, vice-président de la Société nationale belge des chemins de fer vicinaux, président de la Société des chemins de fer et minières Prince Henri.

Vice-presidents :

Alfred **Picard**, membre de l'Institut, ancien ministre de la marine, inspecteur général des ponts et chaussées, président de la section des travaux publics, de l'agriculture, du commerce et de l'industrie au conseil d'État de France;

Ch. **Ramaeckers** (2), secrétaire général honoraire du ministère des chemins de fer, postes et télégraphes de Belgique, administrateur de la Société nationale belge des chemins de fer vicinaux.

Ex-presidents of the sessions, members ex-officio :

Stuyvesant **Fish**, director, Yazoo and Mississippi Valley Railroad;

Nicolas **de Pétroff**, ingénieur général, membre du conseil de l'empire de Russie;

Alfred **Picard**, above mentioned;

Right Hon. Lord **Stalbridge**, chairman, London & North Western Railway;

P. **Weissenbach**, président de la direction générale des chemins de fer fédéraux suisses.

Members :

W. F. **Allen** (3), general secretary and treasurer, American Railway Association;

G. C. C. **Ambt** (1), directeur général des chemins de fer de l'État danois;

Sir George J. **Armytage** (1), Bart., chairman, Lancashire & Yorkshire Railway;

N. **Baïdak** (2), ingénieur, conseiller d'État actuel, directeur de la Compagnie du chemin de fer Moscou-Vindau-Rybinsk, président du comité permanent des conférences consultatives techniques des chemins de fer russes;

Frank **Barr** (1), third vice-president and general manager, Boston & Maine Railroad;

Beaugey (3), inspecteur général des mines, directeur des chemins de fer de l'État français;

Gustav **Behrens** (1), director, Midland Railway;

Richard **Bianchi** (2), ingénieur, directeur général des chemins de fer de l'État italien;

CHANGES

IN THE

CONSTITUTION OF THE PERMANENT COMMISSION

SINCE THE EIGHTH SESSION

(July, 1912)

Member ex-officio who is deceased :

Right Hon. Lord **Stalbridge**, director, London & North Western Railway.

Member who is deceased (vacancy unfilled) :

J. V. Mendes **Guerreiro**, ingénieur, inspecteur général des ponts et chaussées de Portugal.

New members :

Edson J. **Chamberlin**, president of the Grand Trunk and of the Grand Trunk Pacific, elected member in place of Mr. Hays, who is deceased.

Joseph de **Daragane**, ingénieur, conseiller d'État actuel, directeur du chemin de fer Riga-Orel.

Dinkelmann, président de la direction générale des Chemins de fer fédéraux suisses, elected member in place of Mr. Flury, who is deceased.

Ritter Bruno von **Enderes**, ingénieur, directeur général du chemin de fer Aussig-Teplitz.

Sir Guy **Granet**, general manager, Midland Railway, elected member in place of Sir Henry Oakley, who is deceased.

E. P. **Ripley**, president of the Atchison, Topeka & Santa Fe Railway, elected member in place of Mr. Frank Barr, who has resigned.

E. H. **Stieltjes**, ingénieur civil, membre du conseil de contrôle de l'État sur les chemins de fer néerlandais.

Vogel, Geheimer Regierungsrat, vortragender Rat im Reichseisenbahnamt, elected member in place of Mr. Elsner, who is deceased ([1]).

([1]) A few changes have occurred in the titles of members of the Commission. The names and titles given below are now correct :

A. **Dubois**, ingénieur, administrateur honoraire des chemins de fer de l'État belge, vice-président de la Société nationale belge des chemins de fer vicinaux, président de la Société des chemins de fer et minières Prince Henri, président de la Compagnie internationale des wagons-lits et des grands express européens;

ALFRED **Picard**, membre de l'Institut, ancien ministre de la marine, inspecteur général des ponts et chaussées, vice-président du conseil d'État de France ;

STUYVESANT **Fish**, director, Missouri, Kansas & Texas Railway ;

P. **Weissenbach**, ancien président de la direction générale des Chemins de fer fédéraux suisses ;

N. **de Baïdak**, ingénieur, conseiller d'État actuel, directeur de la Compagnie du chemin de fer Moscou-Vindau-Rybinsk, président du comité permanent des conférences consultatives techniques des chemins de fer russes, président de la Compagnie du chemin de fer Armavir-Touapse ;

Beaugey, inspecteur général des mines, ancien directeur des chemins de fer de l'État français ;

A. **Dethieu**, administrateur honoraire des chemins de fer de l'État belge ;

JULES **Ludvigh**, conseiller intime, membre de la Chambre des magnats, ancien secrétaire d'État et ancien président de la direction des chemins de fer de l'État hongrois, président de la Compagnie du chemin de fer Kaschau-Oderberg, administrateur de la Compagnie internationale des wagons-lits et des grands express européens ;

EMMANUEL **Rousseau**, conseiller d'État, membre du comité consultatif des chemins de fer, directeur honoraire des chemins de fer au ministère des travaux publics de France ;

R. **Sarre**, Geheimer Oberbaurat, Präsident des Königl. Eisenbahnzentralamtes ;

K. **Steinbiss**, Ober- und Geheimer Baurat, Präsident der Königl. Eisenbahndirektion, Kattowitz.

Appendix I^bis.

REPORT OF THE COMMISSIONERS,

appointed to audit the accounts for the period from 15 April 1901 to 15 April 1906.

In accordance with the mandate received by them from the Congress, at Washington, on 13 May 1905, the undersigned Commissioners have examined the management account presented by the Permanent Commission for the period from 15 April 1901, the date of the last audit, to 15 April 1906 They have found that it accords with the books, a comparison of which with the vouchers has been duly made, and they have pleasure in testifying to the perfect regularity of the figures.

The definitive account on 15 April 1906 thus shows a cash balance of 34,590·25 francs.

The undersigned append to the present report a comparison made between the expenses of the period under examination and those of the preceding quinquennium, showing, for the present period, a difference of minus 20,430·73 francs (see annex I).

The present report should, in conformity with article 19 of the statutory rules, be presented to the Congress due to assemble at Berne, together with the preceding report, which was communicated to the Permanent Commission on 6 July 1901 (see annex II), with a view to their being appended to the official report of the Congress.

Brussels, 6 October 1906.

The Commissioners :

L. Carlier, P. de Tchérémissinoff.

Annex I to the report of the commissioners, of 6 October, 1906.

COMPARISON OF EXPENSES,

for the periods 1901-1902 to 1905-1906 (Washington) and 1895-1896 to 1900-1901 (Paris).

NATURE OF EXPENSES.	Seventh session (Washington).		Sixth session (Paris).		DIFFERENCES for the seventh session :				The provisional account, including the estimates for 1905-1906, shows :

(1) The sum of 627,823·83 francs has to be augmented by 57,259·01 francs belonging to the financial year 1900-1901 (sixth session), but paid in 1901-1902 (seventh session).

Annex II to the report of the commissioners, of 6 October, 1906.

REPORT OF THE COMMISSIONERS

appointed to audit the accounts from 15 April, 1896 to 15 April, 1901 (1).

In fulfilment of the mission entrusted to them by the Congress at Paris, on 29 September, 1900, the undersigned Commissioners have examined the *provisional* management account presented by the Permanent Commission for the period from 15 April, 1896 to 1 September, 1900 and laid upon the table at the sixth session.

They have, in addition, verified the *definitive* account embracing the complete period from 15 April, 1896 to 15 April, 1901. They have found it in accordance with the books, supported by the requisite vouchers.

The operations of this period of five financial years may be summed up as follows :

Cash in hand on 15 April, 1896 . . fr.	10,383·71
Receipts and loan	657,008·54
Together . . . . . fr.	667,392·25
Expenses liquidated.	630,106·68
Surplus of receipts . . . fr.	37,286·17

The definitive account thus shows a cash balance, on 15 April, 1901, of 37,286·17 francs.

Brussels, 6 July, 1901.

The Commissioners :
L. DE PERL, L. CARLIER.

(1) See the *Summary of Proceedings* of the sixth Session (p. 291) : " The meeting appointed Messrs. Carlier (France) and de Perl (Russia) auditors."

Appendix II.

PROGRAMME OF EVENTS

Saturday, July 2nd.

From 2 to 6 p. m. — Registration of delegates.

Sunday, July 3rd.

From 9 a. m. to 2 p. m. — Registration of delegates.

Monday, July 4th.

From 9 a. m. to 2 p. m. — Registration of delegates. Constitution of the lists of sections.

At 5 p. m. — Reception of the members of the eighth session of the Congress by Dr. Forrer, head of the department of posts and railways. **Formal opening.**

At 8.30 p. m. — Evening party at the Casino rooms, given by the municipal council of the city of Berne.

Tuesday, July 5th.

At 9 a. m. — Meetings of the sections.

At 2 p. m. — Meetings of the sections.

At 4 p. m. — Visit to the Hasler telegraph works.

Wednesday, July 6th.

At 9 a. m. — Meetings of the sections.

At 2 p. m. — Meetings of the sections.

At 4 p. m. — Visit to the Tobler chocolate factory.

Thursday, July 7th.

Excursions for delegates to the Bernese Oberland and to the Lake of the Four Cantons.

Friday, July 8th.

At 9 a. m. — Meetings of the sections.

At 2 p. m. — Meetings of the sections.

At 4 p. m. — Visit to the Roll foundry.

Saturday, July 9th.

At 9 a. m. — Meetings of the sections.

At 2 p. m. — Meetings of the sections.

At 4 p. m. — Visit to the water-power and electric plant of the city of Berne.

Monday, July 11th.

At 9 a. m. — Meetings of the sections.

At 2 p. m. — Meetings of the sections.

At 4 p. m. — Visit to the gas-works and to the Ryff weaving-mill (1st party).

Tuesday, July 12th.

Excursions for delegates to Lausanne-Montreux and to Zurich.

Wednesday, July 13th.

At 9 a. m. — Meetings of the sections.

At 4 p. m. — Visit to the Felsenau spinning-mill and to the Ryff weaving mill (2nd party).

Thursday, July 14th.

At 9 a. m. — Meetings of the sections.

At 2 p. m. — General meeting.

At 4 p. m. — Visit to the central telephone office.

At 7.30 p. m. — Banquet tendered by the Federal Council, followed by an entertainment.

Friday, July 15th.

At 9.30 a. m. — General meeting.

Saturday, July 16th.

At 10 a. m. — General meeting and formal closing of the session.

VISITS TO WORKS, EXCURSIONS AND RECEPTIONS

Reception of the members of the Congress by the city of Berne, Monday 4 July 1910, at 8.30 p. m., at the Casino.

Berne local committee.

President :

Mr. R. Winkler, technical manager of the Federal Railway Department.

Members :

Mr. Adrian, president of the *Berner Liedertafel;*
Mr. Auer, manager of the Lake Thun Railway;
Mr. Bahler, president of the provisioning committee of the federal shooting festival;
Mr. Behrmann, manager of the information bureau;
Mr. Flückiger, president of the development society;
Mr. Bracher, president of buildings committee of the federal shooting festival;
Mr. Dinichert, assistant secretary at the federal political department;
Mr. von Fischer, president of the municipal council;
Mr. Henzi, president of the *Kreisgesangverein;*
Mr. Keller, architect of the federal buildings management;
Mr. Könitzer, member of the executive council of the canton of Berne;
Mr. Kreis, colonel;
Mr. Probst, lieutenant-colonel;
Mr. Sand, member of the general administration of the Federal Railway;
Mr. Schieb, gentleman;
Mr. Steiger, mayor of the city;
Mr. Trüssel, president of the town orchestra;
Mr. Vuilleumier, head of the advertizement department of the Federal Railway;
Mr. Widmer, professor of gymnastics;
Mr. Wälchli, president of the general gymnastic society.

Chief secretary :

Mr. Gribi, secretary at the Federal Railway Department.

Assistant secretary :

Mr. Leumann, official at the Federal Railway Department.

Hardly arrived at the federal city, and but a few hours after leaving the great hall of the Casino, where the opening ceremony had taken place, the members of the Congress, accompanied by their ladies, once more turned their steps towards the beautiful building, of which Berne may justly be proud, in response to the invitation of the municipal council.

At the entrance, pretty young girls, in the charming and picturesque Berne costume, offered flowers to the arriving guests. At 8.30 the great hall, as well as the citizen's hall, brilliantly illuminated and decorated with perfect taste, already sheltered the majority of the Congress members; the federal, cantonal, municipal and local authorities were extensively represented, as well as the Swiss and the foreign press. Small tables were laid everywhere, except in the great hall, where there was only one row of them next to the walls, so as to leave the whole central part available for the free circulation of the guests. The bad weather unfortunately prevented them from walking about on the great terrace and enjoying the incomparable view generally to be obtained there. The town orchestra, hidden on the platform by a screen of green, performed the finest pieces of its repertoire; sumptuous buffets were arranged and an excellent cold supper was served, together with very good wine.

By a delicate attention, the municipal council desired to prevent this gathering having anything of a formal or official character, so that the members of the Congress should from the first day be able to feel the charms of the hospitality which the old city of Berne offered to them; no speeches were made, and Mr. de Steiger, the amiable mayor of the town, even seemed desirous of avoiding the thanks and grateful acknowledgements of his guests.

It was a truly picturesque gathering, where many of the languages of the world were represented and where the delegates who attended former sessions at Washington, Paris, London, etc., very soon renewed the excellent relations they had formed in one or the other of those capitals; a very cordial reception at which the newcomers, seeing the pleasantness of these meetings and encouraged by the simplicity of the Swiss hospitality which was offered to them so good-heartedly, very soon felt as much at their ease as the old ones. But the hour advanced and the sectional meetings were going to begin next morning, with their hard and arduous work, which would leave but little time for pleasure. In the opinion of everybody, it was too soon that parting became necessary. All the members of this charming gathering will certainly retain the best recollection of Bernese cordiality and of the first evening passed by the members of the Congress in Berne.

Excursion to the Bernese Oberland, Thursday 7 July 1910.

Local Oberland Committee.

President :

Mr. Burkhart-Gruner, president of the administration Council of the Bernese Oberland Railway.

Members :

Mr. Borter, innkeeper, at Interlaken;
Mr. Brawand, innkeeper, at Interlaken;
Mr. Liebi, manager of the Steam Navigation Company on the lakes of Thun and Brienz;
Mr. Liechti, traffic manager of the Jungfrau Railway;
Mr. Matti, president of the Development Society at Interlaken;
Mr. Dr. Michel, State councillor, president of the Casino Society at Interlaken;
Mr. Müller, manager of the Victoria Society at Interlaken;
Mr. Räuber, president of the administrative Council of the popular bank at Interlaken;

Mr. Seewer, president of the Interlaken municipality;
Mr. Seiler, deputy of the great Council, at Bönigen;
Mr. Seiler, innkeeper, at Interlaken;
Mr. von Steiger, traffic manager of the Wengernalp Railway;
Mr. Wirth, traffic manager of the Bernese Oberland Railway;
Mr. Wirth, innkeeper, at Interlaken;
Mr. Wyder, innkeeper, mayor of the Interlaken commune.

Secretary :

Mr. Hartmann, manager of the information bureau at Interlaken.

Head of the Excursion :

Mr. O. Sand, member of the general administration of the Federal Railway.

Assistants :

Starting from Berne : Mr. Dinichert, secretary at the Federal political Department;
Starting from Thun Hofstetten (ship) : Mr. Liebi, manager of the Steam Navigation on the lakes of Thun and Brienz;
Starting from Scherzligen (railway) : Mr. Kunz, president of the administrative Council of the Lake Thun Railway;
At Interlaken : Dr. Michel, state councillor;
For the 1st group, Beatenberg : Mr. Hartmann, manager of the information bureau at Interlaken;
For the 2nd group, Schynige Platte : Mr. Burkhart-Gruner, president of the administrative Council of the Bernese Oberland Railway;
For the 3rd group, Mürren : Mr. Wirth, traffic manager of the Bernese Oberland Railway;
For the 4th group, Wengernalp-Scheidegg : Mr. von Steiger, traffic manager of the Wengernalp Railway and Dr. Michel, State councillor;
For the 5th group, Lötschberg Railway : Mr. Hirter, president of the administrative Council of the Lötschberg Railway.

It rained! It rained pitilessly and old visitors asked themselves rather doubtfully what an excursion into the mountains would be like in such weather.

But the majority of those members of the Congress who had selected the Oberland as the place of their excursion did not allow themselves to be intimidated by the bad weather and started from Berne cheerfully, relying on their good star and on the cordiality of their Swiss friends to make up for the absence of sun should the latter remain hidden. The arrival at Thun and at Scherzligen took place under very pleasant conditions which put everybody in a good humour. Charming girls, clad in the picturesque Bernese costume, awaited the members at the stations, placed flowers in their buttonholes and presented the ladies with pretty bunches of Alpine roses.

At Scherzligen the school cadet corps was drawn up on the quay, with rifle or crossbow on the shoulder, and the members passed from the train to the ship to the sounds of lively music while guns fired salutes.

All of this had so much local colour, a colour so simple, so wholesome and so cordial, that the members broke out into applause, and it was in the middle of cheers which were returned from the shore that the ship took the excursionists to the end of the pretty lake of Thun, whose beauties were unfortunately hidden by the mist.

At Beatenbucht and at Interlaken the excursionists were divided into groups and then proceeded to the places named in their invitations.

1st group : Beatenberg.

The delegates and their ladies forming the 1st group of the Bernese Oberland excursion, left the steamship *Blümlisalp* and the members of the other groups at Beatenbucht.

They were received on the pier by Mr. Hartmann, manager of the Society for developing the Oberland and secretary of the local reception committee, who placed himself corteously at their disposition and gave them all useful information.

At 9.30 a. m. the members took the cable railway which goes up the Beatenberg, to a height of 1,150 metres (3,773 feet). This line, which is 1,695 metres (1 mile 94 yards) long, was opened to traffic in 1889; the cost of construction amounted to 700,000 francs (£28,000), which corresponds to 413,000 francs per kilometre (£26,585 per mile). From 1889 to 1909, it carried 873,645 passengers, or an average of 43,000 per year.

The difference in height between Beatenbucht station, on the shores of the lake of Thun, and Beatenberg station is 556 metres (1,824 feet); the mean gradient is 34·8 per cent, and the steepest gradient is 40 per cent. The track consists of two ordinary rails and of a rack rail. Each carriage can hold forty-eight passengers, and it is equipped with three brakes, any of which can stop the carriage almost instantly.

In order to start the carriages, the upper carriage is given the necessary overweight, loading it with water if required, to enable it to pull up the carriage which is below.

The railway has two cables which are 32 millimetres (1 1/4 inches) in diameter and have an ultimate tensile strength of 80,000 kilograms (176,370 lb.); these cables were tested at the Zurich federal laboratory and the tests made showed that the factor of safety is ten.

The ascent took sixteen minutes and offered the passengers a series of marvellous views.

When the train arrived at Beatenberg station, a number of carriages awaited the excursionists in order to take them to *Hôtel Victoria*. The weather which had been bad in the morning, improved a little; members were therefore able to take a very pleasant hour's walk on the mountain and enjoy the splendid view over the lake of Thun and the snowy summits of the Bernese Alps.

An excellent lunch served in an irreprochable manner was supplied to the members in one of rooms of the *Hôtel Victoria*, decorated with the flags of the different nations represented at the Congress and with Alpine flowers. The greatest cordiality was prevalent; one of the delegates expressed in a few words the gratitude of everybody and requested Mr. Hartmann to thank the local Oberland committee for the care and the attention shown them.

At 4 p. m. the delegates descended by the cable railway, once more contemplating the magnificent view of the Niesen which is obtained on coming out of the branch tunnel, and soon afterwards they embarked on the *Stadt Bern* which took them to Interlaken, where they rejoined the other groups of excursionists.

2nd group : Schynige Platte.

Wilderswil is the terminus of the Schynige Platte Railway. It was from that station that the members of the 2nd group started the ascent with the same enthusiasm as if it were magnificent weather. And yet the rain continued to fall, but without succeeding in affecting the good humour of the excursionists. They admired the scenery with the eye of faith, for heavy mists obscured the

view and only the valley remained visible. But the latter is so beautiful, it gives such magnificent glimpses of the lakes of Brienz and of Thun that limited though the view was, it was still very beautiful.

At the intermediate station of Breitlauen, there was a stop of several minutes, where the excursionists successfully struggled against the outward damp by "internal stoking" (as one of their kind guides called it) with a glass of Madeira. The top was reached in the middle of a fog which was continually becoming thicker; the rain had ceased but was replaced by snow which fell in great flakes and covered the ground with a white carpet. The thermometer marked —1° C. (30·2° Fahr.), and this made one appreciate to the full the comforts of a warm room where a table covered with flowers awaited the excursionists, and where there was a cordial reception from which all formality was banned.

One gaily sat oneself at the table, with the hidden hope that the sun would succeed in conquering the fog and the snow. This hope was not realized, but everybody was in such high spirits and the hosts were so pleasant that one finished by forgetting the weather and only thought of the cordiality of the assembly.

At dessert, Mr HUBERTI (*Belgium*) rose and addressed the following remarks, which were received with much applause by the company :

"Ladies and gentlemen, do not be afraid; I am not going to make a speech. However short such a one might be, it would be out of place at this friendly gathering where all formality has been carefully eliminated. But I particularly wish to thank in my own name, and in the name of my Belgian friends, and I think I may add in the name of all of you as well, the organizers of this delightful reunion. They have solved a difficult problem. They have shown themselves superior to the sun, and an excursion which for a single tourist would have been a lamentable failure, has been converted by them into a day of pleasure which will always be a most pleasant recollection to us. I therefore raise my glass to the health of the organizers of this excursion, and in particular to Mr. Burkhardt whose kindness and extreme amiability you have all been able to appreciate during our journey."

Mr. BURKHARDT remarking that the programme had provided for neither toasts nor speeches, regretted that he was unable to reply in French to Mr. Huberti, and thanked the latter for his kind words. The organizers, he stated, did all they could to ensure the success of the excursion, but they could not compel the sun to join them, in order to enable their visitors to admire the beautiful mountains about them. Mr. Huberti's words would result in adding to the cordiality of the meeting and would perhaps recall to its duties the sun, which at that moment seemed as if it might break through the curtain of snow. Mr. Burkhardt expressed the hope that before the time for departure arrived, the skies might clear, if only for a few minutes, so as to make visible the magnificent panorama of the Bernese Alps. But he expressed the hope, should this not prove to be the case, that before the delegates left Berne the sun would favour them; and he invited them very cordialy to profit by it and to come once again to the Schynige Platte.

The afternoon was passed in very animated conversation; the female employees of the hotel, grouped in a corner of the room, gave popular songs which were much enjoyed by the guests, and when the hour for departure arrived, everybody was surprised how quickly the time had flown.

3rd group : Mürren.

The members forming the 3rd group of the Oberland excursion, thirty-five in number, parted from the 2nd group at Wilderswil and directed themselves towards Mürren, and took the Grütschalp cable railway. They were truly carried up into the clouds! Up above, clouds, down below, same view! They observed attentively pastures which were still visible, the mossy fir-trees which were along the iron road, the splendid Alpine flora, among which one saw bell-flowers of all sizes and shades, thistles of all kinds, Alpine roses, blue gentians, etc. During the ascent, a sharp eye could see that the Staubbach waterfall is very beautiful, but the mists which surrounded it did not allow everyone to distinguish it. Lighted up by a bright sun and surrounded with its rainbow, it would be a very different sight!

The members of the local committee charged with accompanying the guests took their place at the back of the train and by their merry jests brought back a ray of gaiety and proved to their guests that in Switzerland one knows how to be cheerful under difficulties. At Grütschalp, all changed from the cable line to the electric line. Suddenly the train stopped, then it started again, with difficulty it seemed. One heard the cracking of a whip and the cheerful sound of bells; one looked out and wondered whether double-heading had become necessary! This is what had happened : the driver of the train tried to drive away several cows who were taking a walk on a track; but as they were unable to find any way out they thought it advisable to trot ahead in front of the train! At the *Kurhaus* a reception, warm in two senses, attended the delegates who could not refrain from an appreciative exclamation when they entered the dining room, beautifully decorated with rhododendrons. An ample lunch was served to the sounds of an excellent orchestra.

An alteration had to be made in the official programme, as the walk which it included could not be taken. The local committee knew how to make up for it, and as no yodeller was there to entertain the guests, it yodelled itself in an excellent manner, and in addition sung sundry Helvetic songs!

The room was soon full of cheerfulness. The time passed so quickly that everybody was surprised when the clock struck four and reminded one that it was time to start. During the descent there was more wind, and rain, and snow; the torrents and the waterfalls alone were beautiful.

4th group : Wengernalp-Scheidegg.

In spite of the rain which had been falling continuously since an early hour, a body of more than two hundred members took the train of the Wengernalp line at Lauterbrunnen, in order to go to the freshly-fallen snow and to the eternal snow. Some chilly people went into carriages equipped for a winter service, while the sons of Albion and their cousins from over the seas boarded the carriages used for the summer service. Each one received, with much pleasure, a charming collection of picture postcards graciously presented by the Wengernalp Railway Company.

The hour for departure had arrived; the train went ahead and proceeded silently on its journey, for the first time, for that day was just the day on which electric traction was inaugurated. At last good-bye to Lauterbrunnen and to the Staubbach fall, which is surrounded by a large number of small falls fed by the continuous rain of the last few days, and

then the view was hidden by entering a long tunnel, lit up electrically. After leaving the tunnel, the train continued its ascent through the fog and passed along the Wengen plateau, saluted by its inhabitants. It then reached Wengernalp, where the animal which is symbolic of Berne bade the arrivals welcome.

The young girls of the district, wearing their pretty Oberland dresses, the Simmenthal head-dress ornamented with a crown of rhododendrons, presented to the train the flags of the States represented at the Congress, while the Interlaken male choir intonated a song in order to salute the guests and the Fatherland. During the lunch, the Interlaken choir gave happy moments to everybody, enabling one in this way to appreciate how song is cultivated on the free soil of Switzerland, even in the most retired valleys of the Alps.

Soon after the arrival at the Little Scheidegg, the weather looked as if it would clear; but at 2 p. m., at the moment of starting back to Interlaken, snow began to fall heavily and continued till it gave place to rain.

5th group : Lötschberg.

In spite of the unsatisfactory state of the weather, one hundred and six members, among whom were several ladies, met at the placed fixed for the start of the 5th group, which was under the direction of Mr. Kunz, the president of the Lake Thun Railway.

When passing Spiez, the excursionists admired the electric cars wich will soon run between that station and Frutigen.

On the arrival of the train, the guests were accommodated in a dozen open breaks comfortably equipped with good rugs, and several closed carriages received the ladies and Mr. Comtesse, president of the Confederation, who honoured the excursion with his presence.

The skies remained covered, but did not prevent enjoying the beauties of the road from Frutigen to Kandersteg, which presents such charming and varied views.

At Kandersteg lunch was given at the *Hôtel de l'Ours*, and the guests seated themselves at table with an appetite sharpened not only by exercise, but also by the fresh and light air. During lunch time a ray of the sun gave for a moment the hope of better weather.

Mr. Hirter, president of the Lötschberg Company, rose, as he said, not to make a speech, but only to give particulars of the visit to the installations.

When the time came, the whole assembly started on the way under the leadership of the amiable general manager of the works, Mr. Zürcher, and of his engineers who were very polyglot in their attainments and who gave every information about the works with indefatigable readiness.

After walking through the workshops, seeing a drill at work, and noticing the very interesting operation of pointing the drills, the delegates mounted the small cars which are used by the workmen in order to take them into the tunnel; and the compressed-air locomotive took them quickly to kilometre 3. This part was quite completed and one saw the air conduit, formed by a partition and one of the sides of the tunnel, through which the fresh air was led up to this point. A blower then took this air and sent it, in iron piping having a diameter of 50 centimetres (1 ft. 7 $^{11}/_{16}$ in.), to the working face. The blower and its motor were on a carriage, and could be moved on as the work advances. The electric line here also terminated in a transformer which was on a carriage, which also could be moved on.

As the tunnel is of double-track section

and is very well ventilated, the stay in it left no unpleasant feelings.

Outside the delegates again found the breaks and the carriages, and the return journey was begun.

A half-way stop was made for a short visit to the charming " Blue Lake", so prettily surrounded with fir trees and with rocks. Its water is remarkably transparent, and those who had time to go on it in small boats were enchanted.

The Lötschberg Company offered refreshments, Swiss champagne, in the pretty refreshment chalet, and everybody carried away a souvenir, in the shape of a chromo, showing a pretty landscape; these were courteously presented by the tenant of the chalet, who is well known under the name of the " Blue Lake Director ".

The guests took the train at Frutigen in order to return to Interlaken.

* * *

The different groups of the Oberland excursion met again at Interlaken in order to be present at the banquet given at the *Hôtel Métropole*, the *Hôtel Victoria* and the *Hôtel des Alpes*.

The weather had not had the least influence on the cheerfulness of the members and everyone was pleased, in spite of everything, with his day.

At dessert Mr. Lutz, the mayor of the town, made the following speech :

" Ladies and gentlemen, in the town where your Congress is at present holding its session, in the federal city of Berne, a monument of bronze is erected on an eminence; it represents a young man, his eyes turned towards the glittering summits of the Alps which hide the horizon. This is the statue of the man whom Berne honours most, the statue of the great Albert von Haller.

" During centuries our Alps only inspired men with horror, with fear and with terror; all those who were not forced to live in their neighbourhood fled them.

" It was given to Haller, thanks to his investigating spirit, to be one of the first to place his traveller's staff on the mountains, to walk through their valleys and their abysses and to discover their beauties, thus rising superior to the prejudices of the men of his time. Haller thus became the herald of our Alps, the one who revealed in the clearest way to his contemporaries and to posterity, the charm, the majesty, the beauty and the grandeur which our unappreciated mountains concealed.

" And yet, after that, nearly a hundred years passed before the foot of man was first placed on the top of the Jungfrau; mankind only followed Haller's appeal with fear and trembling; it was reserved for present times to understand the mountains, and to make their magic attraction felt everywhere. Thanks to your constructions, gentlemen of the winged wheel, and to those in whose footsteps you followed, our Alps which were ignored so long have become the meeting-place of the whole world which sends us year by year caravans of those who feel the need of coming and of gaining strength on our mountains, in our valleys.

" And as this traffic became developed, so did the star of Interlaken rise. After a very modest start, our town has gradually become the centre for all the tourists to the Oberland. And the existing importance which Interlaken has acquired is closely dependent on your work and on that of your predecessors, thanks to the ribbon of steel which connects us with other nations, and to the hardy exploits which have enabled you to conquer the mountains.

" Fully cognizant of all this, it is with quite special satisfaction that we today wish you, ladies and gentlemen, a cordial welcome in our district.

" In the name of the population of Interlaken and of its authorities, whom I here represent, I raise my glass to your health."

In answer to this friendly welcome, Mr. DE PRÉAUDEAU, vice-president of the general council of bridges and roads of France, and delegate of the French government, returned thanks in the following terms :

" Ladies and gentlemen, it was for a member of the Permanent Commission to express to the municipality of Interlaken the gratitude of the Congress delegates for this brilliant reception; it is owing to his absence, caused by an unforeseen obstacle, that I have to speak here.

" The sumptuousness of this entertainment does not make us forget gratitude due to the local organizing committee for having enabled us, by suitably-combined excursions, to admire, in spite of the unfavourable weather, a certain number of the picturesque spots of which Switzerland is justly proud.

" In this district, so celebrated as a centre for Alpine excursions, we do not know what to admire the more : the beauties of nature or the talent of the engineers who by their bold work have made it possible to bring this marvellous scenery within the reach of visitors who are tired or hurried.

" The latter fully appreciate the great aptitude of the Swiss nation in discharging the rites of hospitality, so luxuriously exercised today on our behalf.

" We will not forget to include in our thanks the Interlaken Casino Society, which has invited us to a concert followed by a firework display, so as to finish, in the midst of yet another entertainment, this day which has already been so well occupied.

" I lift my glass in honour of our hosts and drink to the prosperity of the city of Interlaken." (*Applause.*)

While these speeches were made at the *Hôtel Métropole*, Mr. MICHEL, State councillor, president of the Interlaken Casino Society, made the following speech at the *Hôtel Victoria* :

" Ladies and gentlemen, it is in the names of the city of Interlaken and of the Bernese Oberland that I have the honour of wishing you a hearty welcome, a wish bearing the imprint of much greater cordiality than could have been the case thirty or forty years ago. It suffices, in fact, to compare the very different attitude of other nations towards you, now and in the past, in order to form even an approximate notion of how great and strong must have been your spirit of initiative, your capacity for work, your creative power which never retreated in front of any danger, of any responsibility !

" You do not even retreat before the gods : you do not even retreat before Jupiter Pluvius, who in spite of our applications to him, has refused to give his rule to the sun or to the queen of our Alps, the Jungfrau. All the same you have carried out your day's programme.

" Time has been necessary in order that all might understand your work, and thirty or forty years ago you would have run a considerable risk in many inhabited places of being received with stones thrown at your heads, whereas today the populations everywhere express their respect and their gratitude to you, for now they know that you bring with you prosperity and peace and goodwill among nations.

" But it has not always been so, and you know this better than I do. Thus at the distant period when the progress of which you are the representatives made unavoidable changes necessary in the methods of communication, cries of indignation were raised. One heard, more than once, and nearly everywhere, strong protests; and history records, in France for instance, the violent sarcasms of Thiers, in the time of Louis-Philippe, denouncing the railway as a smoky toy which would not last for six months; and the celebrated scientific deductions of a François Arago that a locomotive would not be able to move!

" Well! In all countries, in Germany as in France, in Italy as in Switzerland, very great men made mistakes.

" Were all these recriminations foolish? This is not the time for considering this question

and I will not even discuss the objection so often raised of the destruction of fine views.

" There is a French proverb which says, you can't make omelets without breaking eggs, and it is true that those iron roads which at present extend over the whole world, have occasionally taken from a place its individuality, from a landscape its picturesqueness. Alas ! Gentlemen, you have made omelets and your engineers sometimes added seasoning, more than was desired. But what is some small corner damaged and some few interests necessarily injured, as compared with the benefits which all humanity owes to your energy and perseverance? What do any justifiable criticisms amount to as compared with the wealth which you have spread in all countries of the world, and with the light you spread over the whole world !

" Well, gentlemen, the Bernese Oberland has at all time looked on railways with favour and it is with impatience that we await the opening of the new lines of the Lötschberg which are now being built, and of the Moutier-Granges line, lines which will very materially improve our communications with neighbouring countries. However the Interlaken railways still leave a good deal to be desired in the Brunig-Lucerne direction, a great tourist centre with which we are only connected by a narrow-gauge mountain-line, a considerable part of it being a rack line. The desire of being connected by a good standard-gauge line with the St. Gothard will always remain an object of our desires.

" But Interlaken has every confidence in the future and it is with a grateful heart that it wishes you good luck by my feeble voice. In saluting your superb work, in bowing respectfully before your fellows, the Bernese Oberland gives welcome to the hardiest, the most beneficent pioneers who, by establishing closer and closer relations between the countries, promote a uniformity of interests among the nations which will tend more than anything else, to make war impossible in the future, by spreading in the whole universe fruitful ideas of justice and peace among a regenerate people ! " (*Applause.*)

Dr. Röll, head of the section at the Imperial ministry of railways, Austria, chief delegate of the Austrian government, vice-president of the session, answered in the following terms :

" Ladies and gentlemen, allow me to express on your behalf a few words of gratitude, simple but coming from the bottom of my heart, to the very amiable welcome with which Dr. Michel has greeted us. From the moment the Congress delegates set foot on Swiss territory, they have, both themselves and those belonging to them, been literally overwhelmed with marks of the greatest attention, with a charming friendliness and an overpowering hospitality. The brilliant programme of receptions organized by the administrations of the Swiss railways for the benefit of the members of the Congress included for today this visit to the Bernese Oberland which is worthily being ended in this incomparable Interlaken. The very distinguished president of the Swiss local committee, Mr. Winkler, thought it necessary, at the opening ceremony, to add to the information he gave us about the proposed excursions, the remark that they would take place whatever the condition of the weather, because even in bad weather the mountains were beautiful ; that is absolutely true, for even if the Jungfrau hides the magic beauty of its majestic forms in the clouds, and if the huge snowfields of the other mountain giants do not reflect the rays of the sun, the view which is offered to our eyes is none the less of a kind calculated to exalt us and overwhelm us at the same time. It is accordingly no wonder that the Congress members have not allowed the bad weather to stop them from undertaking this excursion. The pleasure of tarrying in the bosom of sublime nature is doubled for us by the fact that we can admire its splendours in the company of our Swiss colleagues, and that we can tell them, while under the direct influence of the impressions received, how grateful we are to them for having given us the opportunity of seeing, from so near, one of the most beautiful parts of their

country, so rich in natural beauty, and how happy we are in being able to enter into the most friendly relations with them. The days we have passed here will leave a profound impression in our minds. They will continue to live in our recollection, together with a feeling of gratitude towards all those who have rendered our stay in Switzerland so exceptionally interesting and agreeable. It is with these sentiments that I lift my glass and ask you to drink to the prosperity of the Bernese Oberland and that of its most precious jewel, the beautiful Interlaken." (*Applause.*)

At the *Hôtel des Alpes*, it was Mr. Seewer, president of the municipality of Interlaken, who bid the delegates welcome in the following terms :

" Ladies and gentlemen, I have been charged with the pleasant duty of wishing you a hearty welcome, on the part of the authorities of Interlaken. They are moreover not alone in being delighted with your visit. The whole population of the valleys and villages which you have seen today, or rather which, as you may have guessed, exist in the fog which is hiding them, adds its welcome and its good wishes to those of our authorities.

" I feel it my duty to thank those who are at the head of the administration of the Federal Railway, the Railway Department and the Federal Council, for having thought of our little corner of the country when they arranged the programme of the entertainments to the Congress. We also thank all those who, having to choose between the different excursions provided for them, gave the preference to our district. And we certainly are entitled to a feeling of pride when we see how numerous are the delegates who have given their preference to the Bernese Oberland.

" Ladies and gentlemen, we duly appreciate the honour of your visit of today. Tributaries of international traffic that we are, we fully recognize the enormous power represented by those who manage the transport enterprises, and we know that in our age railways and steamships rule the world.

" Ladies and gentlemen, you are today the guests of a small nation of mountaineers, of simple morals and antiquated habits, but their welcome is none the less cordial. We can show our visitors neither castles, nor monuments, nor sumptuous palaces; our smiling valleys and our beautiful lakes form our wealth and our pride, as also the majestic giants among our mountains, draped in their eternal covering of ice and snow. It is to show you these that we took you today on the lake of Thun, into the charming Lütschinen valley, to the Schynige Platte, to the Scheidegg and from Lauterbrunnen to Mürren, in order to give you a full view of the queen of our Bernese Alps, the always beautiful Jungfrau. But unfortunately Jupiter Pluvius has spoilt both your pleasure and ours. Instead of a blue sky and a brilliant summer sun, we have had rain, mist, snow! Our queen of the Alps has wrapped herself in her thickest veil, perhaps to show her disdain for those wicked men who are bold enough to encircle her august waist with their bands of steel And thus the whole magnificence of our Alps has not been made manifest to your eyes. We can only tell you that we deeply regret this, and we request you to recognize at least our good will, unfortunately or no avail.

" We equally regret that your visit is so short. The happy party now assembled here will soon break up, and its members will once more become dispersed all over the world. But in spite of the bad luck you have had, we venture to hope that you will keep a kind remembrance of us and of our little country.

" It is with this hope that I raise my glass and empty it in honour of our very valued guests. Long may they live! "

This speech was followed by prolonged applause and several delegates expressed the deep gratitude of all taking part in the Oberland excursion, for the very cordial welcome received at Interlaken.

After the dinner the excursionists returned to the Kursaal where a brilliant display of fireworks terminated the day.

Excursion to central Switzerland.
Thursday, 7 July 1910.

Local Lucerne Committee.

President :

Mr. Schmid, manager of the Steam Navigation Company on the lake of the Four Cantons.

Members :

Mr. Dietler, ex-president of the administration of the St. Gothard Railway;
Mr. Ducloux, municipal councillor at Lucerne;
Mr. Fellmann, traffic manager of the Rigi Railway;
Mr. Kolb, traffic manager of the Stansstad-Engelberg Railway;
Mr. Riedweg, innkeeper, president of the Casino Committee at Lucerne;
Mr. von Schumacher, member of the executive Council of the canton of Lucerne;
Mr. W. Winkler, traffic manager of the Pilatus Railway;
Mr. Zingg, president of the administration of the Vth district of the Federal Railway.

Head of the Excursion :

Mr. R. Winkler, manager at the Federal Railway Department.

Assistants :

Starting from Berne : Dr. Bonzon, secretary of the Federal Railway department;
At Interlaken : Mr. Wirth, traffic manager of the Bernese Oberland Railway;
Starting from Thun : Mr. Morgenthaler, manager of the Emmenthal Railway;
At Lucerne : Mr. Schmid, manager of the Steam Navigation Company on the lake of the Four Cantons;
For the 1st group, Rigi : Mr. Fellmann, traffic manager of the Rigi Railway;
For the 2nd group, Pilatus : Mr. W. Winkler, traffic manager of the Pilatus Railway;
For the 3rd group, Engelberg : Mr. Kolb, traffic manager of the Stansstad-Engelberg Railway;
For the 4th group, St. Gothard : Mr. Zingg, president of the administration of the Vth district of the Federal Railway.

It was in a pouring rain, violently driven by the west wind, on Thursday, 7 July 1910, that those taking part in the excursion to Central Switzerland boarded the special train, which was to take them to Lucerne, at Berne at 7.15 a. m.

The run took two hours and a quarter; members read the papers, conversed, discussed the chances of any improvment in the weather, and looking through the windows covered with damp, saw the clouds low down, floating around the fir trees of Entlebuch.

At Lucerne things were as at Berne, and with open umbrella one walked to the quay where two saloon boats of the Steam Navigation Company on the Lake of the Four Cantons awaited the members.

The groups going to Pilatus and to Engelberg both took the direction of Alpnach, while the groups going to the Rigi and to the St. Gothard travelled together as far as Vitznau. The two boats, the *Ville de Lucerne* and the *Schwyz*, were prettily decorated with roses; a cold and seductive collation reanimated the courage of the faint, and it was to the sound of the Bernese march, played by an Italian orchestra, that the members of the Congress, passed in front of the celebrated quays of Lucerne. The green grass and the blue

lake did not — alas — produce their usual bewitching effect.

1st group : Rigi.

At Vitznau, the excursionists forming the first group boarded the carriages of the Rigi Railway. The view hardly extended to 20 metres (66 feet) on each side of the line : here one also saw a muddy torrent, there a cow which looked at one seriously, then a small roadside station, a peasant's chalet, a hotel scarcely visible in the fog.

At noon : « Rigi-Kulm, all change! » One entered the waiting-room of the station, for one could not see the great *Rigi-Kulm Hotel* which is a few yards off; an obliging conductor had to show the way. In a moment the comfortably-warmed rooms of the hotel were invaded; it was a great time for picture postcards. At half past twelve lunch was served, to which everyone of the members did full justice. But a lunch, although accompanied by music and served like clockwork by a battalion of waiters, can not go on for ever. Accordingly after coffee, while some few members, either very courageous or very conscientious, ventured into the fog and went off to the highest point of the mountain, the others, either as actors or as spectators, assisted at the dancing of the youthful.

At 3 p. m., there was a general summons, and the train left at 3.15 p. m. But whereas on the way up, silence had been predominant, the descent was more lively. Nature itself seemed desirous of being less cruel. Rifts in the fog allowed deep gorges and a part of the lake to be seen.

At Vitznau the members again took the boat which delivered them at 5.30 at the *Schweizerhof* quay, where they scattered to the right and to the left in order to visit the interesting town of Lucerne.

2nd group : Pilatus.

In spite of the unpromising aspect of the weather, about forty delegates and thirty ladies took part in this excursion. Groups II (Pilatus) and III (Engelberg) embarked at Lucerne at 9.40 a. m. on a special steamer, beautifully adorned with flags, and went to Stansstad, where the 3rd group left the steamer in order to continue its journey by rail to Engelberg. The 2nd group remained on the steamer and went on to Alpnachstad, the terminus of the Pilatus Railway, after passing under the Aacheregg bridge. The voyage was made pleasant by an ample supply of refreshments and by excellent music.

The Pilatus line, which was built in 1889 with great boldness, is of great interest from the technical point of view. The difference in height between Alpnachstad (440 metres [1,443 feet] high) and the Pilatus-Kulm station (2,070 metres [6,790 feet] high) is 1,630 metres (5,347 feet). The line is 4,610 metres (2 miles 1,520 yards) long; its mean gradient is 38·1 per cent and it steepest gradient is 48 per cent : the run up to the terminus station takes an hour and twenty minutes. The cost of construction amounted to 2,400,000 francs (£96,000).

The station of the Pilatus Railway was beautifully decorated in honour of the excursionists who were musically received by the town orchestra of Alpnach. Several special trains conveyed the guests to Pilatus-Kulm. After passing the interesting Wolfort gorge, the international guests were saluted at Aemsigen Alp by mountaineers, with waving flags, with Alpine horns, and with jodels; the bells of the cattle browsing around completed this Alpine picture. Unterwald girls, dressed in all their native finery, offered the guests tempting fruit. At Pilatus-Kulm the members were able to see the wonderful

view which extends over Lucerne and the Lake of the Four Cantons. Unfortunately the sun did not succeed in piercing the heavy fog, and the majestic summits covered with eternal snow remained invisible. The guests then assembled in the large hall of the *Pilatus-Kulm Hôtel*, richly decorated with Alpine flowers, in order to partake of lunch; during this time the orchestra of the Lucerne *Palace Hotel* made itself heard. Then came, in honour of the international guests, the formal opening of the new gallery called the "Oberhaupt". This interesting gallery connecting the hotel, through the Oberhaupt, with the Pilatus-Kulm Railway station, is cut in the rock and a number of openings are provided, which give magnificent views and where the eye plunges into giddy depths. The work took three years, and the last shots were fired the day before the Congress visit. As the weather was bad, the opening ceremony took place in the hall of the hotel instead of taking place on the spot. It consisted of a theatrical representation. The scenery represented the entrance to the Oberhaupt gallery. The genius tutelary of the mountain, surrounded by artistically-dressed gnomes (represented by children of the employees of the Pilatus Railway), came out of the depths of the gallery, and bade the guests a poetic welcome; the goblins then distributed bouquets of Alpine flowers among the members of the Congress.

This performance was loudly cheered. Although the time for departure approached, several visitors went in for the pleasures of a dance

As the weather had in the meantime improved, most of the guests visited the Oberhaupt gallery, and then left the Pilatus-Kulm at 3 p. m. and proceeded, via Alpnachstad and Stansstad, to Lucerne.

3rd group : Engelberg.

The excursionists going to Engelberg left the boat at Stansstad and boarded the pleasant carriages of the Stansstad Engelberg Railway which were to take them to their destination. The train travelled up the Aa valley, where one ould see at various places the floods which resulted from the last melting snow. Many a member no doubt asked himself whether he would safely arrive at his destination, and whether the impetuous river would not exhibit its destructive powers. There is there certainly a very important subject which the delegates could discuss : " The strengthening of the roadbed of mountain lines running along impetuous torrents subject to sudden and abnormal rises, from the point of view of the safety of the delegates of the Congress, making an excursion on one of those lines ". But there was no need for raising this question. The track, it is true, had been carried away at several points, but it was repaired and nobody thought that he was passing over uncertain embankments or provisional bridges.

Engelberg : " *Alles usstige !* " (All change!) A small walk served as appetizer. The village does not extend very far and in five minutes one arrived at the celebrated convent, but unfortunately its doors were closed.

At this moment it seemed as if the mountain summits wished to become clear. One even saw a beam of sunlight on the snow on the Titlis, and a hope arose : the weather is going to clear up, and after lunch it will be possible to admire the summits covered with fresh snow !

After a comfortable and perfectly-served lunch at the *Grand Hôtel Cattani*, the excursionists went to the church where an organ recital was given in their honour. This performance with its music, sometimes gentle, sometimes reverberating,

made one somewhat forget the thickness and rawness of the air outside.

The concert finished, one left Engelberg, After a run of a few minutes there was a stop coupling on the rack locomotive. The carriage assumed an alarming inclination, for one was on a gradient of 25 per cent. The small locomotive checked the speed of the train, thanks to its good engines, and one arrived without trouble at the bottom of the steep gradient where the locomotive was uncoupled and replaced by a motor car until Stansstad was reached. The excursionists there again met their companions from Pilatus, with whom they returned to Lucerne.

4th group : St. Gothard.

The members of the 4th group left the boat at Flüelen, where a special train awaited them. The large windows of the carriages made it easy to admire the scenery. At Altdorf attention was drawn to the large amount of damage caused by the last flood. From here the valley contracts and soon becomes a wild gorge in which the Reuss forms a roaring torrent. The long series of works by which the St. Gothard tunnel is approached begins; it is a nearly-uninterrupted succession of tunnels, of viaducts, of embankments and of cuttings. As the excursionists penetrated into the mountain, the sky became clearer and clearer until a few rays of the sun reached the rock walls and the summits around them. The lunch at the Göschenen refreshment room was to everybody's taste. During the return, the smiling shores of the lake of Zug were much admired.

* * *

At 6.30 p. m. all the excursionists found each other in the three following hôtels : *Hôtel National*, *Palace Hotel* and *Hôtel Suisse*, where very good dinners were offered to them.

At the *Hôtel National*, Mr. de Schumacher, member of the executive council of the canton of Lucerne, who presided, rose and proposed the following toast in German, in French, in English and in Italian successively :

" Ladies and gentlemen, I have been entrusted, as member and representative of the government of the canton of Lucerne, with the pleasant task of welcoming you here and thanking you for the honour of your visit.

" Switzerland, as compared with most of the States which are represented here, is a small and modest country ; but that does not prevent it from holding its own position in railway development, in following with the greatest interest the questions involved and in taking an active part in their progress. It may well be said that our main lines across the Alps and our mountain railways have engaged the attention of many other countries.

" The International Railway Congress is celebrating its XXVth anniversary. It is no doubt by chance that it is celebrating this jubilee in Switzerland and that some of its members on this occasion are visiting Lucerne. We are grateful for this chance, an we consider ourselves very honoured by this meeting of the Congress on our soil and by this visit which will permanently connect with it the name of Lucerne.

" After hard-working meetings at Berne, you have taken a day of rest and you have devoted it to a visit to Central Switzerland. The weather has been as unfavourable to you as possible and the skies have shown you a persistent ill-humour. They will not yield to the men who wage a continual strife with the natural forces in order to open out, at the cost of a thousand difficulties, the most remote regions and compel them to give room to the locomotive. Is that not a perfectly intelligible feeling ? And that is alone why today the amiable and gracious phalanx of

ladies throws a ray of light into this dark picture and warms up all hearts.

" It is more especially to you, ladies, but also to you, gentlemen, that I address my wish of welcome. I thank you for your visit and I raise my glass to your health and to the prosperity of the Congress."

Mr. COLSON, of the Permanent Commission of the Congress and member of the *Institut de France*, answered in the following terms :

" Ladies and gentlemen, the Permanent Commission of the Railway Congress has given me the pleasant task of today thanking in its name our hosts, to whom we are indebted for our very pleasant stay in Switzerland. And in the first place I wish to address all our thanks to the authorities of the canton and of the town of Lucerne for their gracious welcome, and to their representative Mr. von Schumacher for the very flattering words he has just pronounced.

" We have today been conducted and entertained by the Swiss Organizing Committee, and we have seen the programme it had drawn up carried out with that faultless regularity to which it has accustomed us, and which is so essential and at the same time so difficult to attain. It received the disinterested assistance of the local transport enterprises, of the steamship companies and of the Rigi Railway Company, whom we also all wish to thank. So excellent was the organization and so good everybody's humour, that in spite of the bad weather, we have had the opportunity of passing a very pleasant day.

" Ladies and gentlemen, as I am today representing the Congress, I would like to say in its name how happy we all are to find ourselves among the Swiss people during this session. The modern development of transport has not led only to meetings for considering special questions, such as ours. The extension of relations between nations, which it has made possible, has resulted in the creation of a large number of international bodies intended to promote agreement on innumerable questions affecting the interest of many and various peoples. Some of them have taken the form of bureaux instituted by diplomatic agreement between governments; others are the work of private initiative, ensuring the periodic meeting of the most important of the innumerable congresses held to promote the progress of art, of science, of industry, or of the most varied institutions. Such bodies choose as their domicile two countries small in extent, but great in their action in the world, which their neutrality places outside the rivalries unfortunately inevitable between States called upon to play a more militant part, namely Belgium and Switzerland. In each of them, everyone is accustomed to find a friendly reception, under the influence of which amicable relations become developped and intercourse becomes easier and easier among all.

" As for us, the International Railway Congress, which is a private institution, as the States only stand in our association on the same footing as the private companies, we have our regular domicile in Belgium. But we are happy that one of our periodic meetings has brought us to the other international centre, and deeply grateful for our welcome in Switzerland.

" And as it is to a Frenchman that the distribution of the functions of the Permanent Commission has given today the honour of speaking in the name of all the peoples taking part in the Congress, he may be alloved to add, in the name of his own country, the expression of the high importance he attaches to the excellent relations which have existed for so many years between him and his Swiss neighbours, and to the cordial understanding arrived at in our days between the railways of the two States, an understanding strengthened recently by a treaty for the joint carrying-out of works for the development of international traffic.

" Ladies and gentlemen, in the name of the Railway Congress, I propose to you the health of the town and of the canton of Lucerne, and of the Swiss people! "

At the *Palace Hotel*, the seat of honour was occupied by Mr. Theodor Schmid, mayor of Lucerne, who welcomed the guests in the name of the cantonal and the municipal authorities of Lucerne in the following terms :

" Ladies and gentlemen, in the name of the authorities of the canton of Lucerne, I wish you a cordial welcome to the shores of the Lake of the Four Cantons. You have interrupted your laborious work today in order to pay a visit to Lucerne and to Central Switzerland. We thank you for this honour, which we all fully appreciate. We only regret that your excursion was not more favoured by the weather.

" We would have taken you with pleasure, on a hot July day, to the pure air of our mountains. With what pleasure would we have made you admire, in bright sunlight, the majesty of the Alpine chain, the giants of the mountains with their silver summits, the green pastures, the superb lakes, the classical sites of Central Switzerland! But we were denied this pleasure.

" Our mountains were enveloped in thick mist, the rain fell in torrents. You have even found fresh snow on Pilatus in the middle of summer!

" I venture to hope that later on you will return to Lucerne and to rural Switzerland under more favourable auspices, and that you will then take away with you a better impression than will be the case today.

" The sketch which is shown on the menu of your dinner opens out the prospect of the possibility of undertaking an excursion through the air.

" Ladies and gentlemen, foreigners come to us every year in hundreds of thousands in order to seek rest and to admire the natural beauties of our country. It is essentially to the improvement of travelling methods that we owe this great growth in our visitors. At all times have civilized people considered the improvement of the ways of communication as of capital importance. It is in particular the construction of railways which made an enormous advance possible in this way, a whole transformation. All countries, all nations work in a spirit of noble emulation at the completion of their railway systems, at the improvement of their communications, at facilitating their traffic.

" You will no doubt have remarked that our little Switzerland also has during the course of the last *lustra* completed a fine piece of work. I refer to the piercing of the Alps, by the St. Gothard tunnel, the north entrance of which some of you have visited today. I recall the construction of the Simplon line, which like that of the St. Gothard, is intended to draw closer together the bonds between the countries north and south of the chain of the Alps.

" There must necessarily be a certain uniformity in the construction and the operation of railways and it is the great object of the Congress to promote this uniformity. For the last twenty-five years, the most important representatives of the railway world have been working at the solution of this important question, and we owe almost every valuable step in advance to their disinterested activity.

" I conclude by raising my glass to the always-growing activity of the International Railway Congress! "

Dr. Ulbricht, professor, member of the Permanent Commission of the Congress, councillor of the Saxon ministry of finance, answered in the following words :

" Ladies and gentlemen, you have just heard the friendly words of welcome with which the representative of the canton of Lucerne has greeted us in the name of the cantonal and the municipal authorities, and his appreciation of the importance of our Congress. It is to me that the undeserved honour has come to thank him for his words, as well as for the friendly reception we have had today I of course do so with pleasure and with all my heart, certain as I feel of being able to count on your unanimous support.

" Ladies and gentlemen, when we started

this morning in heavy rain, no doubt we all asked ourselves this disquieting question : " In " what state shall we return tonight ? " And, now, we can answer it in a most consoling way. Thanks to the excellent arrangements prompted by a spirit of generous hospitality, which we owe chiefly to the canton and the town of Lucerne, we find ourselves here assembled together, after our so-well-organized excursion, in a most happy frame of mind. This reminds me of a reflection of the good peasant to whom some one was praising the sun. " That the sun is shining in " broad daylight, that is not surprising. But " that the moon appears at night — well, that is " really remarkable ! " And so we can say, on this day of rain : " To organize an excursion " into the mountains on a fine day, so that the " members enjoy it, that is easy. But to " organize it in such a way that even in such " awful weather everybody is pleased — well, " that is really remarkable ! "

" We are here assembled on the hospitable soil of the canton of Lucerne, after our hard-working meetings, and have the agreeable feeling of no longer being divided into sections and strictly grouped without distinction of nationality. We cannot, it is true, eliminate national differences and political frontiers ; nor do we desire to do so, for we should then eliminate at the same time an important factor in progress, namely competition between nations. But as regards the international relations of railways, we can extend our hands to each other across the frontiers, and as regards the functions and the work of our Congress, we can here, on the shores of the Lake of the Four Cantons adopt with our Swiss colleagues the device of Wilhelm Tell : " We will be but one nation of " brothers ! "

" We owe it to the generous hospitality of our Lucerne friends that we can indulge in these happy feelings and let ourselves be permeated by them.

" Let me express all our gratitude for the kindnesses we have received on Lucerne territory by these few words : " Cheers for the " canton of Lucerne ! Cheers for the beautiful " city of Lucerne ! "

Finally at the *Schweizerhof* it was Mr. Steinmann, councillor of State, who welcomed the members :

" Ladies and gentlemen, I have the honour, in the name of the government of the canton, to bid you a cordial welcome.

" We are delighted that an excursion to Lucerne and to Central Switzerland was included in the programme of the International Railway Congress. I therefore thank you, in the first place, for the honour you have done our canton and its capital, the city of Lucerne. We are proud of being able to greet within our walls, even though but for a short while, a meeting so important to the development of railways. In particular I wish to welcome the ladies who, although fulfilling no official functions, favour our assembly with the charm of their presence.

" Gentlemen, you may feel certain that your work of developing the railways will nowhere meet with more sympathy than in Lucerne, the international metropolis of the hotel industry, as well as in our whole canton and in Central Switzerland generally.

" Ladies and gentlemen, let me give you an instance of that sympathy with which our people and our authorities regard you : it is the fact that Lucerne, as a central point of the tourist traffic, not only gives work to five lines of the Federal Railway, but also to seven mountain railways. Among these lines, those of the St. Gothard, the Rigi and the Pilatus are considered masterpieces in the way of railway building. The canton of Lucerne has also had the honour of possessing the first mountain line of any importance, that of the Rigi, which has served as model and of which I do not wish to speak without recalling the memory of the great engineer Riggenbach. We also have the honour of including among our citizens another authority on the subject of mountain railways, namely Mr. Romain Abt, the inventor of the system known by his name.

" The functions of Lucerne in the matter of the tourist traffic make it necessary to develop its means of communication in every way. It is thus that side by side with our well-managed railways and with our well-managed steamships which plough our beautiful lake of Lucerne, we will soon have a station of dirigible balloons, the first in Switzerland; side by side with communication by water and by earth, there will be communication by air.

" I think I have now demonstrated to you that Lucerne does not lack intelligence in developing its means of communication, as required by modern times, and that it is ready to face any expenditure that may be necessary. I cannot refrain, on this occasion, from speaking of our hotel-keepers, who work with energy and decision at the continuous development of our ways of communication and devote considerable sums to do this.

" Lucerne thus knows what it owes to the men who have devoted themselves to the work of paving the way, by holding meetings, for the improvement of the international railway traffic; for railways are the chief means of communication.

" Ladies and gentlemen, we have unfortunately not been able to show you the beauties of our country in all the splendour of a sunny day. Nevertheless we hope that you will take home with you a good remembrance of this excursion in our little country. May our mountains, our lakes, our valleys, our hills, our historic sites dear to every Swiss heart, always recall to you our Swiss fatherland, and may you especially keep a good recollection of our Lucerne. May the white cross on a red ground, that federal cross which is today decorating all your breasts, recall to you, each time that you see it in your distant countries, a vivid recollection of our peaceful valleys and of your excursion to Lucerne.

" What we hope today is, that in the future there may always be men of science who will devote their time and their work to the development and improvement of ways of communication, more especially railways, in the interests of the prosperity and well-being of all countries.

" It is in that spirit thas I invite you to raise your glasses and drink to the success of the work undertaken by the International Railway Congress ! "

Mr. DE GEDULY, manager of the Hungarian State Railway, returned thanks in these terms :

" Ladies and gentlemen, you will kindly allow me, as vice-president of a section, to answer in your name all the friendly wishes of welcome which have just been addressed to us, and to express our deep and sincere gratitude for the superb reception we have enjoyed today. Our thanks are due in the first place for the Swiss hospitality, for the generosity of the Confederation, of the canton and of the city of Lucerne; it also is due to the very kind administrations of the railways and steamships and especially to our Swiss colleagues, who have worked so hard and so amiably for us.

" A good many years ago, I was at a banquet in Bosnia. And the mayor — a Turk — expressed in his picturesque language his regret that his body was not of glass, so that his guests could see in his heart how he loved them. I think that we could repeat that wish. We, the guests of Switzerland, we would wish at this moment that our bodies were transparent, so that our dear colleagues could read in our hearts. They would find there our deep gratitude, they would convince themselves of our warm sympathy, and they would see that we are filled with admiration for Switzerland and for its institutions.

" Switzerland ! The name alone already made our hearts beat in the days of our youth, and in the course of years, our sincere enthusiasm for the majesty of its natural beauties and for the work of its inhabitants has but increased. There is no doubt that it was in one of his happiest moments that the Lord created this country on which he has bestowed a special affection !

" We all, who have come from all the countries of the world, we admire its snowy summits directed heavenward, its glaciers, its deep

gorges, its lakes of smiling, but occasionally treacherous, waters, its green pastures and its forests; the hospitable appearance and the picturesque charm of its habitations.

" And between these imposing mountains, on the shores of these lakes, there dwells an energetic nation, of upright spirit, whose love of liberty and thirst for progress form its noblest qualities. This nation at all times has had the rare happiness of possessing men who managed its government in a remarkable fashion, but the groundwork of its constitution has been, and still is today, the principle that the people govern themselves. But one particular favour which divine Providence has bestowed on this small nation has been to give them a number of distinguished engineers who have made it possible to conquer the immense difficulties which nature opposes to ways of communication and especially to railways; it is they who with inventive talent and iron will have overcome all the obstacles found in their way, and who have earned the gratitude of the whole world for the boldness of their inventions and for the improvements they have made in the domain of ways of communication.

" Today we have had the opportunity of admiring many of these masterpieces of civil engineering, and the engineers of all countries can warmly congratulate their Swiss colleagues on their fruitful labours.

" Mr. Steinmann has expressed his regrets that the sun did not shine on us today. But let me record that if the sun did not shine in the heavens, the sun of Swiss hospitality has today shed on us its most brilliant light.

" Ladies and gentlemen, I request you to raise your glasses to the prosperity and happiness of the Confederation, of the canton and city of Lucerne, of the railway and steamship administrations, to the health of our excellent and charming Swiss colleagues! Long may they live and prosper! "

All these speeches were much applauded.

After the dinner, the members of the Congress directed their steps to the station, passing through the town of Lucerne which was brilliantly illuminated in their honour; at 9.30 p. m. they boarded a special train which took them back to Bern, Thun and Interlaken.

Excursion to Lausanne-Montreux. Tuesday, 12 July 1910.

Local Lausanne-Montreux Committee.

President :

Mr. C. Decoppet, State councillor, at Lausanne.

Members :

Mr. Barraud, manager of the Lausanne tramways;
Mr. Chatelanat, syndic of Veytaux;
Mr. Chessex, proprietor, at Territet;
Mr. Emery, State councillor, syndic of Châtelard;
Mr. Lacombe, manager of the General Navigation Company on the Leman lake;
Mr. Miauton, syndic of Planches-Châtelard;
Mr. Schnetzler, syndic of the town of Lausanne;
Mr. Stockmar, president of the administration of the 1st district of the Federal Railway;
Mr. Tschumy, innkeeper at Ouchy.

Head of Excursion :

Mr. Sand, member of the general administration of the Federal Railway.

Assistants :

Starting from Berne : Mr. Dinichert, secretary at the political Federal Department;

Starting from Interlaken-Thun : Mr. Wirth, traffic manager of the Bernese Oberland Railway;

Starting from Lausanne : Messrs. Decoppet, State councillor; Lacombe, manager of the General Navigation Company on the Leman lake; Schnetzler, syndic of the town of Lausanne.

The members of the Congress who took part in the Lausanne-Montreux excursion will say that our celebrated Montaigne is for once wrong when he says " the pleasures and good things that we have, there is not one which is not alloyed with some evil and some inconvenience ! "

The whole day was beautiful and the rain, that celebrated rain which was an especial feature of the eighth session of the Congress, did not arrive till the evening, just in time to make the visitors admire the marvellous play of colours the lake of Geneva can produce.

The excursionists, leaving Berne by special trains, arrived at 11 a. m. at Lausanne, where the State council of Vaud and the municipality of Lausanne, with Swiss simplicity and cordiality offered them some welcome refreshments at the Lausanne-Ouchy casino. Flowers were very kindly presented to the delegates and their ladies by a number of charmingly dressed young girls.

At noon, special tramway cars, kindly supplied by the Lausanne Tramway Company, conveyed the excursionists to the three large hotels of Ouchy : *Beau-Rivage*, *Château* and *Royal*, where an excellent lunch was served. The delegates appreciated, as connoisseurs, the special wine grown in the vineyards which are the property of the town; this wine was presented by the municipality of Lausanne.

Mr. Robert Comtesse, the president of the Swiss Confederation, was present, also Mr. Deucher, federal councillor, and representatives of the federal courts, of the State council of Vaud, of the local authorities, of the management of the first district of the Swiss Federal Railway, etc.

The Lake Geneva Navigation Company then invited the delegates to embark on the ships *La Suisse* and *Montreux*, and to go on the classic round of the upper lake by Evian, Bouveret, Vevey, and then on to Montreux. At the start, the delegates passed through two rows of little girls dressed in white and of cabin-boys with long oars. Cordiality reigned on board the ships and the sun, which wanted to see the company, showed up the natural beauties of this wonderful country.

At the Montreux landing-stage, the delegates were received by the local authorities while the town band made itself heard.

Most of the delegates then went to Glion, taking advantage of the facilities granted by the companies operating the Vevey-Montreux, the Montreux-Glion and the Territet-Glion lines.

At Glion, the view was a magnificent, extending from Geneva to the « Dent du Midi », which stood in its majesty and was quite clear, and received unbounded admiration. The Rochers de Naye and the Jaman appeared in their full beauty.

At 7 p. m. the excursionists sat down to the dinners given at the *Montreux Palace* and at the *Grand Hôtel* of Territet. The food was excellent, the wines were delicious, there were excellent orchestras and the floral decorations were magnificent.

At dessert Mr. Emery, the syndic of Châtelard-Montreux, welcomed the delegates in the following words :

" Ladies and gentlemen, one of our most illustrious masters of gastronomy, Brillat-Savarin, has said that a dessert without cheese is like a fair lady who has an eye missing.

" One might add, particularly in these days,

that a dinner without speeches in an imperfect dinner, although I very much fear that the side-dish which my duties as syndic oblige me to offer to you runs the risk of being indigestible. But the speaker who will succeed me will compensate for the lack of my eloquence.

" Ladies and gentlemen, allow me, in the name of the Montreux authorities, to wish you all a cordial welcome and to thank the organizers of this Congress for having included Montreux in today's excursion.

" But allow me also to tell you how disappointed we are and how much we regret that the time you can give us is so short.

" Montreux is not a large place; nevertheless a few hours more would have given you the opportunity of appreciating it more.

" Montreux, as you know, in a tourist resort. That is to say, that the hotel industry plays an important part here. Now it is indisputable that the railway industry and the hotel industry have numerous points in common. You have sleeping cars and dining cars which are nothing but hotels on wheels. Ours are stationary. Just like you, we have continually to improve our installations, we have to keep up to the level of modern requirements and of modern inventions. Thus we both strive for progress. There is one point, however, on which we have not been able to agree, and that is whether it is the railways which bring us the travellers, or whether it is the hotel which attracts the travellers.

" As for me, I think that each has its well-defined function, within its own limits; that these two industries snpplement each other, and that our many mutual interests oblige us to advance hand in hand.

" We will however readily admit that without railways many hotels would no longer have any reason for their existence and would have nothing further to do, except to shut up.

" You will no doubt have noticed the chain of mountains which protects us against the north wind. It is to this natural protection that Montreux owes its reputation, and it is therefore considered a winter resort, and it has been called the Nice of Switzerland; and that is why, when the season is in full swing everywhere else, you will find Montreux like a house abandoned by its masters and its usual guests; and it is this which has prevented it from assuming its most festive garb in order to receive you.

" Nevertheless we hope that you will take away pleasant memories of this short visit here, and whenever it pleases you to see Montreux again, in spring, in autumn or in winter, we will always be happy to receive you.

" Ladies, it is exceedingly pleasant and agreeable to us, whatever our age, whether we are in the hey-day of spring, or whether winter snows have powdered our heads, to wish you welcome and to thank you for having honoured and beautified this dinner with your presence.

" Gentlemen, I express the best wishes that your future conquests in the domains of railways may continue, on your symbolic winged wheels, to progress with every improvement. I raise my glass in honour of the members of the eighth session of the Railway Congress." (*Applause.*)

Mr. Petri, councillor of the Imperial Ministry of railways of Germany, vice-president of the eighth session of the Railway Congress, replied in German in the name of the delegates to Mr. Emery, as follows :

" Ladies and gentlemen, in my capacity of delegate to the Congress, allow me to thank Mr. Emery, the syndic of Montreux, for the very friendly words of welcome which you have just heard.

" The eagerness with which Switzerland undertook to organize the eighth session has been a great gratification to our Association.

" This is proved by the large number of delegates who have come, and all will say that we have come full of liking for Switzerland, that country where there is as much to learn as to admire.

" The special conditions obtaining in this wonderful mountainous country are such that the railway engineer has found vast problems

there, and it is in their strife with the gigantic world of mountains that the Swiss railways have shown their best powers.

" It is with admiration that we look at the energetic Swiss nation under a beneficent government, which has attained an astonishing degree of perfection.

" We are equally full of enthusiasm over the enchanting natural beauties of this blessed land, and the delightful days passed during the eighth session will continue to dwell in the memories of the members.

" These days have acquired a special value, owing to the captivating amiability and kindness with which the representatives of this dear country have striven to receive us, to increase our welfare and to make our stay in this beautiful and hospitable country as happy as possible.

" Today's excursion is yet another proof of this. The authorities of the canton of Vaud have overwhelmed us with their very cordial reception in their delightful country.

" Gentlemen, I express the sentiments of all in addressing to you our warmest and most sincere thanks, and I raise my glass to all those who have received us so cordially in this dear country : long life to them ! " (*Applause.*)

While these friendly words were exchanged at Montreux-Palace, Mr. Miauton, syndic of Planches-Châtelard addressed the following speech to the delegates at the *Grand Hôtel* at Territet :

" Ladies and gentlemen, in our time of quick social evolution, official duties would be a heavy burden if they did not sometimes bring happy rewards to those charged with them.

" As for me, syndic of Montreux, I fully appreciate the value of the agreeable duty which has today fallen upon me, of bidding you all welcome in the name of our beloved city.

" Montreux is having a festival.

" Montreux is happy and proud.

" It is to your presence that it owes this joy.

" It is to the Federal Council that it owes this honour.

" Nothing could gratify us more.

" May I therefore be permitted to express here, our gratitude to the Federal Council.

" Ladies, may you be welcome, you who know, by your charming grace, how to temper so usefully the severity of our preoccupations.

" You are the bright spots in our lives. To please and to charm are your divine privileges which society respects, but which nature alone has given to you.

" And if you have come to the country of the narcissus, that sad flower with the sweet smell, in order to reflect your charming images in the waters of our lake and conquer all hearts, your mirrors, ladies, are too faithful and already all our hearts belong to you, with but one exception, my own, which you will allow me to except out of discretion, firstly because it is too old to be of any value, and because an honest man is not allowed to give away something which no longer belongs to him. No, you have come because you had duties to perform towards the delegates, remembering no doubt that antiquity did not wish that a man should wear himself out by excessive work. Perhaps also out of pure curiosity, in order to see, to learn, to travel, thus illustrating by a very happy action one part of the usefulness of the work of the members of the Congress.

" Gentlemen, may you also be welcome, you who in the intervals of your useful labours, and in order to find a temporary rest from your creative work, come to the foot of these high mountains whose high summits ignorant of the powers of mankind seem to hurl a defiance at you.

" Welcome to you, the greatness of whose work, the legitimate privilege of the chosen few, is only equalled by the loftiness of your ambitions and of your immovable will.

" Welcome to you who know, by the genial association of your nations, how to place the universal well-being above individual interests; how to reduce the vicissitudes of the fortune of the world by the community of interests, and how to create reciprocal friendships between different countries.

" By your conceptions and your works, which bestow on you a large fraction of the economic sovereignty, you raise labouring mankind, releasing from their social prison millions of workers, otherwise mostly victims destined to misery and to starvation.

" It is this steel network, an admirable instrument of influence and of power, whose meshes, every day coming closer together, envelop millions of beings occupied, like you, in passing through this life, which makes you the determining cause of the modern industrial activity. You peacefully prepare future fates, by bringing truth, wealth, science and life to the remotest corners of nature.

" By your struggle, always more intense in the midst of the continually-growing requirements of our modern society, a perpetual manifestation of energy of which your Congress is the expression; by the clear foresight of future possibilities and of duties which your ideal imposes on you, you ensure that peaceful but freedom-bringing revolution from which universal brotherhood will emerge triumphant for all.

" I conclude in expressing the hope that we will again see you with us. Montreux, a small city in the small country of Switzerland, itself a small country as regards the number of its inhabitants, but a great nation in its ideals, hospitable Montreux is grateful to you for the honour you have bestowed on it. In the name of the whole population, once more, I thank you." (*Applause.*)

Mr. KAREISCHA, assistant manager of the traffic department of the ministry of ways of communication of Russia, principal secretary of the 3rd section of the eighth session, replied to Mr. Miauton, the syndic, as follows :

" Ladies and gentlemen, allow me, in the name of the delegates of the Congress, who have met from different parts of the world, to offer our most sincere and most cordial thanks to the Swiss organizing committee, to the cantonal and communal authorities and to the administrations of the different transport establishments and enterprises, for the friendly welcome we have had in your beautifuf country and in the canton of Vaud.

" I therefore raise my glass to the prosperity of Switzerland and to the good health of the authorities mentioned, as well as to the good health of the inhabitants of beautiful Territet! " (*Applause.*)

Mr. PETSCHKOVSKY, engineer of bridges and roads, chief engineer of the traffic department of the Russian South Western Railway, then added the following words :

" Ladies and gentlemen, tonight we arrive at the end of the series of marvellous excursions which have been organized for the delegates of the International Railway Congress. The recollection of the splendid and cordial welcome which we have received in Switzerland will always remain engraved on our grateful hearts. As delegates of railways, we know from experience, what difficulties the reception of such a large number of guests involve and how much extra work this entails on the operating staff. We are at the same time quite competent to appreciate with what skill everything has been organized. I have been amazed at all I have seen, especially at Berne station where all was concentrated. The regularity and the coolness with which the employees carry out their duties in the most difficult and unforeseen cases have very much struck me and have increased my profound respect for the discipline and the intelligence of the employees. With such a staff the Swiss railways are sure of their future and of the continuation of their prosperity.

" In witness of my profound gratitude, I raise my glass in the honour of all the employees, of whatever rank, of the Swiss railways : *Vivant, floreant, crescant!* " (*Applause.*)

The delegates finally went to the Montreux *Kursaal*. The town was decorated and illuminated. On the public places a

flourish of trumpets was heard. Inside the *Kursaal* the orchestra played its finest music to perfection and was much applauded.

But the hour for departure was striking. Too soon, alas, and not without regrets, did the delegates part from Montreux and from the Vaud authorities in order to resume the homeward journey by special train.

This excursion to Lausanne-Montreux was, in the opinion of everybody, most successful and the members taking part in it will certainly never forget it.

Excursion to Zurich, Tuesday, 12 July 1910.

Local Zurich Committee.

President :

Mr. Bertschinger, president of the administration of the district III of the Federal Railway.

Members :

Mr. Bleuler-Hüni, State councillor, at Zurich;
Mr. Bitterli, manager of the Oerlikon works;
Mr. Brunner-Vogt, president of the administrative Council of the Steam Navigation Company on the lake of Zurich;
Mr. Koch, manager of the wagons works, at Schlieren;
Mr. Dr. Müller, legal adviser to the town of Zurich;
Mr. Neithardt, president of the Development Society of Zurich;
Mr. Nüscheler, traffic manager of the Uetliberg Railway;
Mr. Schoop, member of the administrative Council of the Dolder Railway;
Mr. Studer, manager of the Zurich tramways;
Mr. Zoelly, manager of the Escher, Wyss & C° works, at Zurich.

Secretary :

Mr. Dr. Schumann, secretary of the administration of district III of the Federal Railway.

Head of the Excursion :

Mr. Robert Winkler, technical manager at the Federal Railway Department.

Assistants :

Starting from Berne : Mr. Dr. Bonzon, secretary at the Federal Railway Department.
Starting from Interlaken-Thun : Mr. Wirth, traffic manager of the Bernese Oberland Railway.
For Zurich : Mr. Bertschinger, president of the administration of district III of the Federal Railway.
For the 1st group, Dolder : Mr. Schoop, member of the administrative Council of the Dolder Railway.
For the 2nd group, Uetliberg : Mr. Nüscheler, traffic manager of the Uetliberg Railway.
For the 3rd group, Schlieren : Mr. Koch, manager of the Schlieren wagon works.
For the 4th group, workshops of the Federal Railway : Mr. Bertschinger, president of the administration of district III of the Federal Railway.
For the 5th group, Oerlikon : Mr. Bitterli, manager of the Oerlikon works.

The delegates and their ladies who preferred the banks of the Limmat to the shores of the Lake of Geneva, left Berne by special train at 9 a. m., about three hundred and fifty in number.

The sun was not sulking and its bright rays put everybody into a good temper during the journey from Berne to Zurich, while one quickly passed the substantial

Bernese farmhouses with their great arched roofs, the factories with clear windows and high chimneys, the workmen's dwellings and the private houses which all show the desire of the architect to combine local styles with the most modern comforts. While the " steam-men " talked " compounds " and " superheating ", the electricians complacently drew attention to the high-tension electric-supply lines which run across the country and which " threaten " or " will finally replace " the steam locomotive. These subjects did not seem to have any interest for the ladies, whose attention was more attracted by the chocolate and the soap factories, the dye works and the weaving mills, then by Schinznach Bad, the castle of Habsburg and Baden-les-Bains.

On arrival at Zurich at 11.20 a. m., the different groups of excursionists separated according to their respective destinations.

1st group : Dolder.

The members forming the first group took the Dolder Railway, which is an electrically-operated cable line, going up the slopes of the Zurichberg. This line is 800 metres (875 yards) long, and has gradients of from 95 to 177 per mil. At Dolder station, which is 600 metres (1,968 feet) above sea-level, the members admired the magnificent panorama which presented itself to their eyes.

A feeling of well-being came over the delegates as they approached the Dolder, which is surrounded by a park with charming glades, with terraces around the building, which is in the midst of verdure and of flowers.

The appetites were sharpened by the fragrance of the forest and it was with a feeling of gratitude to the organizers that the guests entered the *Grand Hôtel du Dolder* and took their places at a table prettily decorated with small red roses, a charming decoration in perfect taste. An excellent orchestra added the pleasure of hearing to the pleasure of the sight, and contributed to the gaiety of the guests.

2nd group : Uetliberg.

The members of the 2nd group boarded the blue and white cars of the Zurich tramways which took them to the beautifully-decorated station of the Uetliberg line. Two trains, also adorned with flowers, soon took them up to the summit of the Uetliberg. The standard-gauge line has a length of 9·13 kilometres (5 miles 1,185 yards), and gradients of up to 7 per cent; the difference in height between the two ends is 600 metres (1,968 feet). It first passes through the suburbs of Zurich, and then goes through meadows and orchards to enter the forest, which covers the upper parts of the mountain.

Lunch awaited the visitors at the *Uetliberg Hotel*. The visitors at once took their seats, and at the psychological moment when the company was ready to hear something well said and delicately thought out, Mr. Mauris, director of the Paris-Lyons-Mediterranean Railway Company, gracefully pronounced the following speech :

" Ladies and gentlemen, I feel confident that I interpret your wishes and act in accordance with the general feeling, in expressing our lively gratitude to the organizers of the charming entertainment which has been graciously offered to us today and at which we are now present.

" The Swiss authorities, our colleagues and friends of the Federal Railway, and the representatives of the private railways have provided and arranged everything with a view to amusing us and charming us, to make us appreciate the charm and the beauty of their wonderful country, under many different and varied aspects,

laughing or magnificent. They have known, judiciously, how to break the dry work of the Congress by interesting visits to industrial establishments, or by excursions where everybody could satisfy his taste and his bent. They have thus combined the agreeable and the useful, and they have added to their kindness by graciously inviting our families also to benefit by the facilities which have so generously been granted to us.

" We are grateful to them for their kind and delicate attentions. They have in succession shown to us their smiling valleys, their pinnacles covered with the eternal snows, their glittering glaciers, the lofty summits of their mountains; in short all that forms the attraction of this incomparable country. We have just enjoyed, while ascending the Uetliberg, the magnificent panorama afforded by the Lake of Zurich and by the city nestling on its smiling shores. We shall take away with us an exquisite and ineffaceable recollection of our stay in Switzerland and of the warm welcome we had there.

" Our special thanks are due to the Uetliberg Company which has given us such a hospitable reception, and to its manager who has kindly acted as our guide in our charming excursion. Formerly mountains were an obstacle which repelled travellers. Today they tempt him and attract him, thanks to the remarkable works constructed by the Swiss engineers who have cleverly known how to hang their bold lines to the walls of mountains, and build railways to summits which could formerly only be reached by hardy climbers, but are now within the reach of all.

" I see with pleasure that we have among us a large number of ladies and of younger girls who are accompanying their husbands and their fathers. Their presence adds a charm to this assembly and gives it more life and gaiety. I am sure, gentlemen and dear colleagues, that I express your sentiments in raising my glass to their health. I drink to you, ladies, whom we have today the great pleasure of seeing around these tables."

These words were followed by prolonged applause.

The excursionists then went to the " Kulm ", which is surmounted by a sort of " extra Kulm ", in the shape of a high iron tower. That " extra Kulm " was not to everybody's taste, for the unobstructed view obtained from the top of it is only obtained at the cost of a laborious ascent, while one can see the same view without trouble in successive sections, by walking round the walls. More than one excursionist no longer recognized the Zurich which he saw ten or twenty years ago from the same Uetliberg. The town has pushed out its tentacles in every direction and all those new roofs on the shores of the lake and on both sides of the Limmat give one the impression of a busy hive and of a town which is booming. In the south one sees the Alps, a little screened by disturbing wisps of clouds, and the foreground is a mass of rich green formed by woods, by meadows and by orchards covering beautifully-undulating country. This green is unreal, one delegate remarked who had just come from the burnt country of Algiers.

The hour and the place promoted friendly intercourse and it was with regret that the members took the return journey to Zurich. The same bright clear blue and white cars took them through the streets of the city. The ladies quickly purchased the usual souvenirs and met again at the Tonhalle, which was magnificently decorated for a grand dinner.

3rd group : Schlieren.

The delegates forming the 3rd group met at 11.30 a. m. at the *Hôtel Victoria*, Zurich, where an exquisite lunch was served on small tables. The special train which conveyed them stopped at Schlieren in the middle of the works, for the car works are

in the immediate neighbourhood of the station, with which they are connected by a private branch track. This establishment, which was started in 1902 on a very modest basis, now covers a surface of 12 hectares (29·65 acres), and about a thousand men are now employed there. Its stores of timber are remarkable and represent an average book value of about 800,000 francs (£32,000).

The members were conducted by Mr. Koch, the manager of the works, and by Mr. Kamber, his assistant, who graciously placed themselves at the disposition of the excursionists and showed them successively many wagons of the Federal Railway, tank trucks, cars for the Tramvie luganesie, and for the Chaumont Cable Railway (near Neuchâtel); all the seats of these were arranged on platforms, on a new plan, looking downwards and thus allowing the view to be enjoyed. All these cars were shown in the various successive phases of their construction. Among the details inspected, we may mention two patent devices for preventing fingers from being caught between the hinges, ingenious locks used on the Swiss wagons, installations for autogenous soldering, an automatic fire-alarm and fire-preventer and a large number of other things of equal interest. The delegates then visited the locksmith's shops, the carpenter's shops and others, all equipped with most up-to-date appliances; also the stores, the organization of which was admired by the specialists.

The last part of the visit was reserved to a demonstration of the installations made for the transport of wounded soldiers, which are adopted to two hundred carriages, with three axles, of the Federal Railway. It was with the greatest interest that the excursionists admired this installation, but each of them expressed to himself the wish that it may never be necessary to transform these carriages into ambulances.

Refreshments kindly offered by the works concluded the visit, and it was with their best thanks that the delegates parted from their hosts of the last two hours and returned to Zurich.

4th group : Workshops of the Federal Railway.

Soon after the arrival at Zurich, sixty ladies and gentlemen forming the 4th group met in the dining-room of the *Hôtel du Saint-Gothard*, superbly decorated with roses and with flags of the national colours, where an elaborate lunch awaited them, which took nearly an hour and a half; then a special train conveyed them, together with twenty others who had lunched at the *Hôtel Victoria*, to the new workshops of the Federal Railway. While a small fraction of the excursionists was taken in motor cars to the goods yard, to examine the installations there, the rest of them strolled about the workshops, assisted by a small plan of which each had received a copy, The car workshop is not yet completed, the building only is finished; the inside fittings are still missing in the framework which is to contain the dining-hall and the baths. On the other hand, the locomotive section is in full swing; the excursionists examined it in detail, as well as its annexes, which include the transformer substation, the forge, the shop for turning up the wheels, the boiler house and the stores. The workshops are more particularly devoted to the maintenance of the rolling stock of district III, and at present look after :

308 locomotives, including tenders;
874 carriages;
175 luggages vans;
2,247 wagons.

The delegates then visited with much

interest a small exhibition including a locomotive with Stumpf valve gear, an express locomotive with Brotan boiler and a carriage electric-lighting installation, on the Brown, Boveri & Co. system. The electric accumulator locomotive of the connecting line to the slaughter-houses excited great interest among the technicians. At 3 p. m. this locomotive took the excursionists to the slaughter-houses, which are some little way off, and after a visit to the unloading stages, everybody went to the refreshment room in order to partake quickly of some refreshments. Some of the delegates let themselves be tempted, by the doors which were open everywhere, to enter the superb slaughter-house building in order to examine the interesting installations and see the work of the men from near.

Then the visitors, suitably refreshed, took the tramway which carried them back to Zurich, passing through the whole length of the town, and then took them on to the Zurichberg, at a height of 100 metres (328 feet) above the lake, where they saw the whole panorama of the city. The return journey brought them to the Polytechnic School; finally everybody wandered along on foot through the old city to the Lake the *Tonhalle*.

5th group : Oerlikon works.

A considerable number of the excursionists to Zurich went by a special train on the Federal Railway to Oerlikon, in order to visit the works there. After a short look at the works, which have been much enlarged during the last few years, part of them having been rebuilt entirely, a turbo-alternator set of 4,000 horse-power intended for the generating station in the town of Christiania was started running in the turbine test room. Then the visitors were specially invited to see a shunting locomotive, worked by accumulators, and an electric locomotive of the Lötschberg Railway. The latter was going to be delivered in a few days and set running shortly on the line of access to the Lötschberg (Spiez-Frutingen section); it weighs 88 tons (86·6 English tons). It will be feed with single phase current at 15,000 volts at 15 periods and has two single phase commutator motors of 1,000 horse-power each. Each of these is mounted on a bogie with three coupled axles. This new design has been very carefully worked out in all its details; it deeply interested the distinguished specialists who were pleased to recognize the activity and the success of the Oerlikon works in the domain of electric traction on standard-gauge railways.

After partaking of some refreshments in the waiting-room of Oerlikon station, which had been very prettily decorated for the occasion, the visitors took a special train on the Federal Railway and returned to Zurich.

* * *

The different groups of the excursionists to Zurich reassembled at 5 p. m. in the *Tonhalle* in order to partake of the dinner given in their honour.

This dinner was a great success, for food and drink were exquisite and the " Chambre XXIV " of the *Männerchor* of Zurich added to its beauties by song. Receive our thanks, ye devoted singers, you who with the gymnasts and the marksmen have called into being the valiant Switzerland!

When the time for the speeches arrived, Mr. Bleuler, State councillor, of handsome and serious appearance, rose and made the following speech in German :

" Ladies and gentlemen, the International Railway Congress has done Switzerland the

honour of holding its eighth session within our territory. The States and the administrations of the railways of five continents have sent as delegates to Berne, to the capital of our Federation, the authorities most skilled in the construction and operation of railways in order to examine and discuss, during many laborious meetings, questions of all kinds connected with the construction and operation of railways, and their improvement.

" Gentlemen, you have been kind enough to interrupt your labours, to adjourn your discussions, to leave your meeting-place, and what we feel especially deeply, to bring with you your ladies in order to give the canton and the city of Zurich the honour and the pleasure of your visit.

" Ladies and gentlemen, it is I who have the honour of addressing you a most cordial welcome in the name of the government of the canton of Zurich, and in the name of the municipality of the city of Zurich.

" Our authorities and our people, as well as the establishments which you have today honoured with your visit, feel very happy in welcoming you here and thank you sincerely for your attention. Our country is small as compared with those which you represent and it has but small resources at its command, in the great competition between nations, as compared with those you have available. However we hope that you will have been interested by the visits you have paid today to the workshops of the Federal Railway, to the car-building works at Schlieren, to the Zurich slaughter-houses and to the Oerlikon works; you will have taken away with you the conviction, that in spite of difficulties of an internal and an external order, and of the competition they have to meet, our industries have arrived at a high state of commercial and technical development, thanks to the knowledge of the managers of those establishments and thanks to the skill of the employed.

" Besides you all know, without doubt, that our industries have to fight seriously against their competitors. Our country lacks the most important raw materials, iron and coal. It is true that we are now-a-days trying to replace the latter as much as possible by our " white fuel ", by the power which we obtain from waterfalls. In spite of these difficulties our industries strive by all means in their power, by the quality of their produce, to prove equal to the competition encountered.

" You will have observed, in all our industries, the need and the strong determination, in spite of all difficulties, to keep their establishments and their produce at the height of technical perfection and of commercial suitability. May they always succeed in doing so, for the well-being of the country is wrapped up in the prosperity of our industries.

" Ladies and gentlemen, those of you who have visited the Swiss National Museum have been able to appreciate the value of this jewel of Zurich. In passing through its rooms, you will have been able to grasp the development of the customs and usages of our people from the most remote times until now. I venture to hope that you will take away with you an agreeable recollection of our National Museum. And no doubt Zurich will leave an equally good impression on those who have been able to contemplate it from the heights of the Dolder and of the Uetliberg, and to admire the surrounding country, the beautiful lake of Zurich with its background of snowy mountains.

" You have had the opportunity of visiting the slaughter-houses of the city of Zurich and their modern sanitary installations; you have been through our town with its well operated tramways, its well-kept streets and squares, its drainage, its public fountains, which supply abundance of excellent water, its quays which are of incomparable beauty, and its many other features. Ladies and gentlemen, you will certainly take away with you the impression that the municipal authorities of Zurich have neglected nothing to give the friends and the guests of the city a healthy and agreable stay.

" The water fête tonight, to which the setting sun invites us, will allow you before your departure once more to admire the beautiful situa-

tion of our town and to enjoy the charm of our lake with its shores covered with vine-yards and studded with villas; and I hope that this recollection will decide you to come again to us some day, to pay us another visit.

"I would express once more the great pleasure which the visit of you our guests has given to the authorities of the canton and of the city of Zurich, and I raise my glass to your health in expressing the hope that you will thake away with you pleasant recollections of your visit to Zurich." (*Prolonged applause.*)

Mr. Weissenbruch, general secretary of the Congress, replied in the following speech, not a word of which was lost in the great hall :

" Mr. Councillor, ladies and gentlemen, three gifts are necessary for the happiness of a people as for that of individuals : intellect, strength and beauty.

" Beauty, a beneficent fairy bestowed on Switzerland in the origin of time. The beauties of this wonderful country are innumerable; they are known to the whole world, as is illustrated by the alacrity with which the delegates have come from all countries in answer to the invitation of the Swiss government and of the Swiss Federal Railway.

" The happy inhabitants of this beautiful country also possess the gift of strength, thanks to its superior climate, so healthy, so invigorating, to which so many invalids come in order to regain their health. The bodily vigour of the Swiss has in all historical times been known to be the equal of their courage. They have covered themselves with glory on all the battlefields of Europe. It is through this courage that they succeeded in the mighty task of conquering and then of maintaining their independence in the midst of such powerful neighbours!

" Even at the present day we see the Swiss cantons rivalling each other in the gymnastic training of the young men of an age to serve in the army, and attaching the greatest importance to physical exercises.

" Finally, ladies and gentlemen, *mens sana in corpore sano!* Switzerland possesses the gift of intellect equally with the gift of strength. It proves that by the part it plays in the intellectual life of its neighbours. This fact is made all the more remarkable that it would seem its efforts would be counteracted by its political decentralization, by the diversity of its races, of its languages, of its religions!

" Enclosed today within the narrow limits of customs frontiers, Switzerland has understood the great importance of intellectual culture in the economic strife which has succeeded the heroic strife of nations. It has understood that it could only conquer by the attainments of its engineers, of its chiefs of industry, of its business men, by the skill of its workmen. The cantons accordingly spend very large sums on the popular education. The higher educational institutions of Switzerland can serve as patterns; it has many libraries and museums, its periodical publications are many in number.

" But, ladies and gentlemen, Switzerland possesses not only these three gifts, of intellect, of strength, and of beauty, which make for its happiness. It also possesses other gifts which add to our happiness : namely the gifts of the heart.

" I am sure of being your mouthpiece when I express our deep gratitude for the charming, the delicate, the attentive hospitality we have received here. We shall never forget the touching cordiality of our hosts and I think that I can assert in the name of all the foreigners present that we shall leave behind in this country durable, eternal friendships!

" Ladies and gentlemen, I propose to you to raise your glasses to the health of all those who have contributed to the charming entertainment which we have enjoyed today, and are still going to enjoy this evening :

" To the Swiss Federation! To the Federal Railway and to the private railways! To the canton and to the town of Zurich! To the local committee! To the Tramway Company and to the Steamship Company! "

This speech was uproariously applauded, and the delegates, whose excellent mood continued, went to the quay, where two fine ships, the *Helvetia* and the *Ville de Zurich* were waiting for them. Can we describe the delight of this trip on the lake? Can we describe the beauty of its shores? Can we describe the enthusiasm aroused by the illumination of the roadstead? No, let us leave it to everyone to tell in his own way of that never-to-be-forgotten night when all Zurich was on the water, gliding along in small boats and surrounding the delegates of the Congress with a sympathy of which a thousand bright fireworks showed the depth. For a long time to come the delegates will still hear the singers of "Chambre XXIV" ardently glorify their country in the profoundly-moving song of *Oh mein Heimatland*. Zurich, to you our gratitude!

Banquet on 14 July 1910, offered by the Federal Council.

About twelve hundred people accepted the invitation of the Federal Council to the official entertainment organized in honour of the Railway Congress Association, in the fine Federal Drill Hall. Several members of the Federal Council, the diplomatic corps, the chiefs of the international offices which are located in Berne, and other distinguished guests attended this assembly, which was adorned by the presence of a large number of ladies. The Hall presented a magnificent spectacle. During the dinner, the excellent town orchestra executed a choice programme.

Towards the end of the dinner, Mr. Comtesse, President of the Swiss Confederation, made the following speech:

"Ladies and gentlemen, allow me in the first place to discharge a duty in which you will join. Just as you sent a message of sympathy to the United States on the occasion of the celebration of its independence day, let me today address, from this place, a message of sympathy and of friendship, and our best wishes for prosperity, to the French Republic, which today celebrates its *fête nationale*.

"Gentlemen, to you who are delegates at the eighth session of the Railway Congress Association, I bring you in this banquet, which marks the approaching end of your labours, the cordial compliments of the Federal Council and I express the hope, which will not be frustrated, that this session, which marks the twenty-fifth anniversary of your activity, will prove the starting point for further progress in the organization and operation of railways.

"It is always a refreshing spectacle to see scientists and technicians coming from all parts of the world, as you have come here in great numbers, to communicate to each other the results of their work and their experiments and to investigate together how further progress can be added to the progress which has already been made, and further conquests to the inheritance of humanity.

"Among all the congresses which meet from time to time in different parts of the world, there are none exceeding in importance that of the congresses of your association, none whose work is more useful, for its object is the continual improvement of the greatest public service in the world.

"They have, moreover, this result: by the meeting of a large number of scientists, of engineers, of inventors, of technicians, there is demonstrated, more than in any other way, the beneficial sovereignty of science and of men of science, that continually-growing unity of the world of science, that natural result of the unity of science itself, a distant, but certain, omen of a future of which you, gentlemen, are the forerunners, when the nations will be but a vast association of workers collaborating in the same work, the advancement of science to benefit

View of the federal drill hall arranged for the banquet given to the members of the Congress by the Federal Council, 14 July 1910.

humanity, knowing no other strife but the peaceful strife of work and making no conquests, except over nature and over ignorance.

" They have even this, if possible still higher result, that if they have the object of improving the equipment of iron roads, the quickness and the security of carriage, then they bring more closely together, and establish permanent communication between the men whose mission in the world is the work on railways, that is the work which must most promote the unity of nations.

" Such was also the function which His Majesty the German Emperor attributed to your Congress when he addressed to your session at Washington, five years ago, a telegram in which he said that your Congress Association, in benefiting international traffic, seemed to him the most effective way of fostering mutual understanding and bringing together the nations in peace.

" Must the bringing together which results from a reduction of time and distance not naturally ensure a bringing together in the domains of thought, of sentiment, in mind and in heart? Do not all the ressources which science today places at our disposition assist in this result of bringing governments and nations closer together? Do not the locomotives which run across our frontiers, work at this every day, by continually increasing our facilities for the exchange of produce and by facilitating the movements of men?

" If we all, sons of different nations, have the ambition to serve our respective countries and make them prosper, should we not also have the ambition, not less high, of cooperating in works which have as object not only the material prosperity of humanity, but the policy of mutual understanding, of harmony and of peace, which is the ideal of all of us, and which can not be realized except by the union of men of good will and of conscience, and by the efforts of all.

" Gentlemen, Switzerland will always be proud of having been able to make its small contribution to that work which has as its object the progress you strive for; and it will always be happy every time it is selected as the meeting place of congresses which work, like yours, at works of progress.

" It has, it is true, only modest resources which it strives to supplement by extra goodwill and by the cordiality of its reception, and it would always hope to think it did not fail too much in its object, and that the guests which it receives will retain an agreeable recollection of their visit.

" We would have wished to offer you, during the session of the Congress, sunny days, vistas without clouds, instead of the wet days and too abundant showers which the skies have bestowed upon you. But when I spoke of this to one of the most eminent members of your Association, and when I grieved over this disappointment, he consoled me by saying : " Do not " distress yourself; the Railway Congress is a " working Congress, and the rain only helps " to stimulate our eagerness for work."

" I replied : " The 1910 Congress at Berne " may then be described as follows : There " has been much rain, but there has been much " work."

" I raise my glass in honour of the eighth session of the International Railway Congress Association; I drink to the health of its members! " (*Much applause.*)

Mr. A. Dubois, President of the Permanent Commission of the International Railway Congress Association, answered in the following terms :

" Mr. President, ladies and gentlemen! The International Railway Congress Association is as proud of the great honour done to it by the Federal Government, as it is touched by the friendly and cordial way in which it has been received in your beautiful country. This reception, I may be allowed to tell you, we expected, we promised it to ourselves; for we know how many other associations have been, like us, able to enjoy a hospitality which is always great and generous, always impressed with courtesy and goodwill

" Many of us have come to Switzerland, from all parts of Europe and from beyond the seas. Was not this necessarily so? In addition to the attractions, springing up at every step, which are offered to the traveller by this country so blessed by nature, are there not powerful attractions to the engineer, to the builder and operator of iron roads, to the railway man? Does one not find remarkable and grand solutions, of the most difficult problems which may confront the engineer charged with planning and building railways? Does one not find model constructional works, carried out under the most varied and most difficult conditions? Does one not find a large number of ingenious and rational applications of special systems of traction which science has presented to practice and thanks to which it is possible one can build and operate with advantage, lines of communication which for a long time were considered impracticable?

" Your technical schools, with a perfect organization, have acquired a great reputation in other countries; they produce trained engineers, well prepared for their career, profoundly imbued with the love of work and devoted to their profession.

" The astonishing progress in the domains of electrotechnics has thrown open a vast field for action in which your engineers and your constructors shine.

" The complex and often delicate questions which arise in railway working. have led with you to investigations, to discussions which have aroused a vivid interest in the economic world.

" It was two Swiss jurists who, in 1874, were the initiators of the international legislation concerning the carriage of goods, in force for the last twenty years. And if, as can now be foreseen, and as the wish was expressed at one of the first sessions of the Congress, this legislation is supplemented in the near future by a law controlling the carriage of passengers, one will recollect the learned and deep investigations into the question, published by another Swiss jurist in 1897.

" In whatever direction one explores the vast domain of railways, one always finds indications of the investigations, of the works and of the successes of your countrymen.

" The Congress was certainly in a suitable place with you; we are grateful to the Federal government for giving it us and for having made it so beautiful.

" The work of the eighth session has gone on steadily, and is nearly completed. Soon we shall have to begin our homeward journeys; we shall do so with regret and shall carry away with us a lively feeling of gratitude. Here I am, having arrived nearly at the end of a presidency which has lasted seventeen years. I am happy that today I still am able to act as the representative of a stately assembly in order to express to you the warm and deep sympathies which are aroused in the hearts of all those who have been able to come to your homes, and to live your life, and have themselves been able to appreciate the qualities inherent in your race : an upright nature, a determined spirit, an innate good sense, a patient energy, a love of a simple family life, an incessant search after progress, an ardent patriotism, the inspirer of manly virtues; a whole mass of good qualities which have earned for your country the esteem, the admiration and the respect of the most powerful nations.

" Ladies and gentlemen, I call upon you to raise your glasses : to the greatness, to the unlimited prosperity of the free and proud Swiss nation! " (*Great applause.*)

After this speech, the band played in succession the national anthems of the chief countries represented at the banquet.

Mr. Winkler, vice-president of the Swiss section of the Permanent Commission of the Congress read the following telegram addressed by the President of the United States to Mr. Franklin Lane, senior delegate of te American Government :

" I send greetings to the whole international railway Congress and sincerely hope that their

conferences will result in general benefit and improvement of railway methods."

WILLIAM H. TAFT.

This message was received with prolonged applause.

The banquet was followed by an entertainment given in honour of the Congress by the chief musical and gymnastic societies of Berne.

The programme was carried out in the most successful way; the last part, "*Life in the Swiss mountains*," in particular, was very much applauded.

The entertainment lasted till nearly 1 a. m., and will remain ineffaceable in the memories of all those who were present.

Excursion to the Engadine, on the 18, 19 and 20 July 1910.

It was an animated scene, bearing however the imprint of a certain amount of sadness at leaving the very hospitable city of Berne, of which the Congress had been the spoilt guest during a fortnight, when the remaining members of the Congress, on Monday 18 July, at 9 a. m., boarded the special train which was to take them into eastern Switzerland, among the snowy peaks of the Engadine, to St Moritz, sometimes named the "Mecca of the seekers after health and pleasure".

After an excellent lunch given by the International Sleeping Car Company, the one hundred and fifty members of the Congress arrived at 2 p. m. at Chur, where a special train, provided by the Rhetian Railway Company, awaited them in order to take them through the Grisons by the Albula line, one of the finest creations of the genius of man.

We must not forget to mention that on the way a collection was made for the benefit of those who suffered by the disastrous floods of the Upper Rhine, at Landquart, the sad signs of which appealed to all the travellers.

The Rhetian Railway is a highly-interesting narrow-gauge system from the point of view of a permanent-way engineer. The Albula line, connecting Thusis and St. Moritz, has a gauge of 1 metre (3 ft. $3\,^3/_8$ in.); it goes up the valley, sometimes on the one side, sometimes on the other, gaining height by means of helicoid tunnels of hardly conceivable boldness.

The steepest gradient between Thusis and Filisur is 25 per mil, and attains 35 per mil between Filisur and Bevers; the line rises from a height of 700·50 metres (2,298 feet) at Thusis to one of 1,818 metres (5,965 feet) at Spinas, the culminating point; it then descends to 1,773 metres (5,817 feet) at St. Moritz.

The sharpest curves have a radius of 120 metres (6 chains).

There are many smaller tunnels, having a total length of 10,142 metres (6 miles 532 yards); in addition there is the great Albula tunnel, which has a length of 5,865 metres (3 miles 1,134 yards). The view, from its exit, of the Beverin valley, is very impressive.

The arrival at St. Moritz took place about 5 p m., after three hours of splendid and striking scenery, during which one did not know which to admire most, the picturesque and severe character of the country or the genius of the engineers who were able to reconcile the art of builder with the care of keeping intact the natural beauty of the sites.

Thanks to the excellent organization of the excursion, each member found ready for him at St. Moritz the accommodation which had been reserved for him at the best hotels in the place.

On Tuesday 19 July, a special train awaited the members at 8 a. m., in order to take them across the Bernina pass and bring them close to the Italian frontier.

The Bernina Railway, which connects St Moritz and Tirano, has a total length of 60 kilometres (37·3 miles) and had only been fully opened to traffic a few days before. Electric traction is used; continuous current at 750 volts is supplied by the four electric substations at Campo Cologno, Poschiavo, Bernina Hospiz and Pontresina. At each of these there is a converter set and an accumulator battery; the Brusio power station supplies alternating current at 25,000 volts, 50 periods, to the converters at these substations.

The track has a gauge of 1 metre (3 ft. 3 3/8 in.) and steepest gradients of 70 per mil; the sharpest curves have a radius of 45 metres (2 1/4 chains). The line winds along the slopes of the mountains, through curved tunnels which make it possible to gain considerable height without in any way injuring the beauty of the scenery. There are thirteen tunnels; the two longest are 700 and 300 metres (765 and 328 yards) in length.

The exceptionally favourable weather made this excursion very attractive. The view of the Morteratsch glacier, which soon appeared in its immaculate whiteness, aroused great enthusiasm among the members.

An excellent cold lunch restored the energies of the members at Le Prese, the extreme point of the excursion, and a charming walk along the shores of the lake of Poschiavo quickly passed the time until the return train started.

In the evening, at 8.30 p. m., the members met at the *Grand Hôtel*, where a magnificent banquet was given to them by the municipality and the Society for developing St. Moritz. The excellent food and the seductive wines soon promoted the utmost cordiality among the guests.

During dessert, numerous speeches were made : by Mr. Hoffmann, president of the Society for developing St. Moritz, to welcome the members of the Congress, and by several delegates, in the name of the Congress and of all the countries represented, to thank the local authorities and the people of Switzerland, for the splendid way in which they had been welcomed.

On Wednesday 20 July, an excursion in brakes was arranged to the Maloja in the morning; and in the afternoon one by cable railway up the Muottas Murail. These most successful excursions thus ended the series of voyages organized for the Railway Congress, and they will leave ineffaceable memories in the minds of all those who took part in them.

SUMMARY

OF THE

3rd VOLUME

3rd SECTION : WORKING.

Pages.

OPENING MEETING 1

QUESTION IX. — **Large stations.**

Report No. 1 (all countries except those hereafter), by Messrs. JULLIEN and LEVERVE. (See English edition of the *Bulletin* of February, 1910, p. 909.) . . IX — 3

Report No. 3 (America), by Mr. H. A. JAGGARD. (See English edition of the *Bulletin* of May, 1910, p. 2077.) . . . . . IX — 37

Report No. 2 (Russia, Austria, Hungary, Rumania, Bulgaria, Servia and Turkey), by Mr. A. KAIN. (See English edition of the *Bulletin* of August-September-October, 1910, p. 3363.). . . . . IX — 89

Sectional discussion. . . . . IX — 165

Sectional report. . . . . IX — 192

Discussion at the general meeting . . . . . IX — 192

Conclusions . . . . . IX — 194

QUESTION X. — **Operation of switches and signals.**

Report No. 1 (Austria, Hungary, Bulgaria, Denmark, Germany, Luxemburg, Norway, Rumania, Russia, Servia, Sweden, Switzerland and Turkey), by Professor Dr. ULBRICHT. (See English edition of the *Bulletin* of January, 1910, p. 295.) . . . . . X — 3

Report No. 3 (America), by Mr. E. C. CARTER. (See English edition of the *Bulletin* of March, 1910, p. 1337.) . . . . . X — 67

	Pages.
Report No. 2 (Holland), by Mr. L. H. N. Dufour. (See English edition of the *Bulletin* of April, 1910, p. 1361.)	X — 79
Report No. 4 (other countries), by Messrs. L. Weissenbruch and J. Verdeyen. (See English edition of the *Bulletin* of July, 1910, p. 3319.)	X — 145
Sectional discussion	X — 185
Sectional report	X — 242
Discussion at the general meeting.	X — 242
Conclusions	X — 247
Appendix I : Note of the Administration of the Swedish State Railway in answer to question 16 of the list of questions of Mr. Ulbricht, author of report No. 1	X — 249
— II : Note on the M. D. M. system. Installation in cabin XI (Landy), Paris-Nord, by Anon.	X — 251

Question XI. — Passenger tickets.

Report by Mr. von Stierlin. (See English edition of the *Bulletin* of December, 1909, p. 1769.)	XI — 3
Sectional discussion	XI — 29
Sectional report	XI — 46
Discussion at the general meeting.	XI — 46
Conclusions	XI — 47

Question XII. — Motor vehicles.

Report No. 1 (America), by Mr. C. Peter Clark. (See English edition of the *Bulletin* of November, 1909, p. 1319.)	XII — 3
Report No. 2 (all countries, except Great Britain and America), by Mr. L. Greppi. (See English edition of the *Bulletin* of March, 1910, p. 1273.)	XII — 21
Report No. 3 (Great Britain and colonies), by Mr. T. Hurry Riches. (See English edition of the *Bulletin* of April, 1910, p. 1495.)	XII — 85
Sectional discussion	XII — 165
Report of the 2nd, 3rd and 5th sections meeting jointly	XII — 188
Discussion at the general meeting.	XII — 188
Conclusions	XII — 190

4th SECTION : GENERAL.

	Pages.
Opening meeting	1

Question XIII. — Railways and waterways.

Report No. 1 (Great Britain), by Mr. G. R. Jebb. (See English edition of the *Bulletin* of August, 1909, p. 791.).	XIII — 3
Report No. 3 (America), by Mr. W. E. Hoyt (See English edition of the *Bulletin* of February, 1910, p. 817.).	XIII — 17
Report No. 2 (all countries, except Great Britain and America), by Messrs. C. Colson and L. Marlio. (See English edition of the *Bulletin* of March, 1910, p. 1123.).	XIII — 27
Sectional discussion	XIII — 135
Sectional report	XIII — 158
Discussion at the general meeting.	XIII — 158
Conclusions.	XIII — 159

Question XIV. — Statistics.

Report No. 1 (British colonies), by Sir Thomas Rees Price. (See English edition of the *Bulletin* of December, 1909, p. 1569.)	XIV — 3
Report No. 2 (Great Britain), by Mr. W. M. Acworth. (See English edition of the *Bulletin* of January, 1910, p. 3.).	XIV — 87
Report No. 3 (all countries, except Great Britain, British colonies and America), by Mr. Barriol. (See English edition of the *Bulletin* of May, 1910, p. 2049.) .	XIV — 133
Report No. 4 (North America), by Mr. A. J. County. (See English edition of the *Bulletin* of June, 1910 [2nd part], p. 2985.)	XIV — 161
Sectional discussion	XIV — 257
Sectional report	XIV — 299
Discussion at the general meeting	XIV — 299
Conclusions	XIV — 304
Appendix : Memorandum on the question of statistics, by Mr. J. de Richter. .	XIV — 305

Question XV. — Motor car services.

	Pages.
Report by Mr. J. C. Inglis. (See English edition of the *Bulletin* of December 1909, p. 1735.)	XV — 3
Sectional discussion	XV — 57
Sectional report	XV — 46
Discussion at the general meeting	XV — 46
Conclusions	XV — 47
Appendix : Corrigenda to the report	XV — 48

Question XVI. — Perishable goods.

Report No. 1 (countries using the English language), by Mr. J. M. Culp. (See English edition of the *Bulletin* of December, 1909, p. 1655.)	XVI — 5
Report No. 2 (other countries), by Mr. R. Bloch. (See English edition of the *Bulletin* of June, 1910 [1st part], p. 2319)	XVI — 85
Sectional discussion	XVI — 211
Sectional report	XVI — 233
Discussion at the general meeting	XVI — 233
Conclusions	XVI — 234
Appendix : Addenda to report No. 1 (countries using the English language), by Mr. J. M. Culp	XVI — 237

5th SECTION : LIGHT RAILWAYS.

Opening meeting	1

Question XVII. — Lines belonging to main railways but having not much traffic.

Report by Mr. Quarré. (See English edition of the *Bulletin* of November, 1909, p. 1337.)	XVII — 3
Sectional discussion	XVII — 45
Report of the 3rd and 5th sections meeting jointly	XVII — 65
Discussion at the general meeting	XVII — 65
Conclusions	XVII — 67

Question XVIII. — The working of light railways.

	Pages.
Report by Mr. Plocq. (See English edition of the *Bulletin* of October, 1909, p. 1265, and of June, 1910 [1st part], p. 2707.)	XVIII — 3
Sectional discussion.	XVIII — 33
Sectional report	XVIII — 60
Discussion at the general meeting	XVIII — 60
Conclusions	XVIII — 61
Appendix : Corrigenda to the report	XVIII — 63

Question XIX. — Locomotives and rolling stock of narrow-gauge light railways.

Report by Mr. Moriz Jesser. (See English edition of the *Bulletin* of July 1910, p. 3119.)	XIX — 3
Sectional discussion.	XIX — 119
Sectional report	XIX — 150
Discussion at the general meeting	XIX — 150
Conclusions	XIX — 151
Appendix : Corrigenda to the report	XIX — 154

Question XX. — Transhipment.

Report by Mr. C. de Burlet. (See English edition of the *Bulletin* of January, 1910, p. 451.)	XX — 3
Sectional discussion.	XX — 39
Sectional report	XX — 57
Discussion at the general meeting	XX — 57
Conclusions	XX — 60

VARIOUS MOTIONS.

Pages.

I. — Motion relating to the drafting of the list of questions of the ninth session : " Utility of studying the question of freight-car interchange and demurrage " . 1

Note, by Mr. W. F. Allen. (See English edition of the *Bulletin* of January 1910, p. 11.) 3

Sectional discussion 21

Sectional report. 24

Discussion at the general meeting 24

Resolution. 25

II. — Miscellaneous matters 26

Addenda to various motions.

Note on the development of the Russian railways, by Mr. Pierre de Tchérémissinoff . . 28

CLOSING OF THE EIGHTH SESSION.

Closing ceremony. (See English edition of the *Bulletin* of December 1910, p. 3854.) . 1

Appendix I : Permanent Commission and Executive Committee. (See English edition of the *Bulletin* of December, 1910, p. 3839.). 6

Changes in the constitution of the Permanent Commission since the eighth session . . . . . 8[1]

— I[bis] : Report of the Commissioners appointed to audit the accounts for the period from 15 April 1901 to 15 April 1906 . . . . . 8[3]

— II : Programme of events. (See English edition of the *Bulletin* of December 1910, p. 3650.) 9

— III : Visits to works, excursions and receptions. (See English edition of the *Bulletin* of December 1910, p. 3842.) 11

ATTIC SHELVING
